  TO '/etc/TDE/export.exp'
  IDENTIFIED BY password
```

```
  WITH IDENTIFIER IN 'AdoxnJ0uH08cv7xkz83ovwsAAAAAAAAAAAAAAAAAAAAAAAAAAAA',
                     'AW5z3CoyKE/yv3cNT5CWCXUAAAAAAAAAAAAAAAAAAAAAAAAAAAAA';
```

The following statement exports master encryption keys from a password-protected software keystore to file `/etc/TDE/export.exp`. Only the keys whose tags are `mytag1` or `mytag2` are exported. The master encryption keys in the file are encrypted using the secret `my_secret`. The key identifiers are found by querying the `V$ENCRYPTION_KEYS` view.

```
ADMINISTER KEY MANAGEMENT
  EXPORT KEYS WITH SECRET "my_secret"
  TO '/etc/TDE/export.exp'
  IDENTIFIED BY password
  WITH IDENTIFIER IN
    (SELECT KEY_ID FROM V$ENCRYPTION_KEYS WHERE TAG IN ('mytag1', 'mytag2'));
```

The following statement exports all master encryption keys of the database to file `/etc/TDE/export.exp`. The master encryption keys in the file are encrypted using the secret `my_secret`.

```
ADMINISTER KEY MANAGEMENT
  EXPORT KEYS WITH SECRET "my_secret"
  TO '/etc/TDE/export.exp'
  IDENTIFIED BY password;
```

In a multitenant environment, the following statements exports all master encryption keys of the PDB `salespdb`, along with metadata, to file `/etc/TDE/salespdb.exp`. The master encryption keys in the file are encrypted using the secret `my_secret`. If the PDB is subsequently cloned, or unplugged and plugged back in, then the export file created by this statement can be used to import the keys into the cloned or newly plugged-in PDB.

```
ALTER SESSION SET CONTAINER = salespdb;
ADMINISTER KEY MANAGEMENT
  EXPORT KEYS WITH SECRET "my_secret"
  TO '/etc/TDE/salespdb.exp'
  IDENTIFIED BY password;
```

Importing Keys: Example

The following statement imports the master encryption keys, encrypted with secret `my_secret`, from file `/etc/TDE/export.exp` to a password-protected software keystore. It also creates a backup of the password-protected software keystore before importing the keys.

```
ADMINISTER KEY MANAGEMENT
  IMPORT KEYS WITH SECRET "my_secret"
  FROM '/etc/TDE/export.exp'
  IDENTIFIED BY password
  WITH BACKUP;
```

Migrating a Keystore: Example

The following statement migrates from a password-protected software keystore to a hardware keystore. It also creates a backup of the password-protected software keystore before performing the migration.

```
ADMINISTER KEY MANAGEMENT
  SET ENCRYPTION KEY IDENTIFIED BY "user_id:password"
  MIGRATE USING software_keystore_password
  WITH BACKUP;
```

Reverse Migrating a Keystore: Example

The following statement reverse migrates from a hardware keystore to a password-protected software keystore:

```
ADMINISTER KEY MANAGEMENT
  SET ENCRYPTION KEY IDENTIFIED BY software_keystore_password
  REVERSE MIGRATE USING "user_id:password";
```

Adding a Secret to a Keystore: Examples

The following statement adds secret `secret1`, with the tag `My first secret`, for client `client1` to a password-protected software keystore. It also creates a backup of the password-protected software keystore before adding the secret.

```
ADMINISTER KEY MANAGEMENT
  ADD SECRET 'secret1' FOR CLIENT 'client1'
  USING TAG 'My first secret'
  IDENTIFIED BY password
  WITH BACKUP;
```

The following statement adds a similar secret to a hardware keystore:

```
ADMINISTER KEY MANAGEMENT
  ADD SECRET 'secret2' FOR CLIENT 'client2'
  USING TAG 'My second secret'
  IDENTIFIED BY "user_id:password";
```

Updating a Secret in a Keystore: Examples

The following statement updates the secret that was created in the previous example in a password-based software keystore. It also creates a backup of the password-protected software keystore before updating the secret.

```
ADMINISTER KEY MANAGEMENT
  UPDATE SECRET 'secret1' FOR CLIENT 'client1'
  USING TAG 'New Tag 1'
  IDENTIFIED BY password
  WITH BACKUP;
```

The following statement updates the secret that was created in the previous example in a hardware keystore:

```
ADMINISTER KEY MANAGEMENT
  UPDATE SECRET 'secret2' FOR CLIENT 'client2'
  USING TAG 'New Tag 2'
  IDENTIFIED BY "user_id:password";
```

Deleting a Secret from a Keystore: Examples

The following statement deletes the secret that was updated in the previous example from a password-protected software keystore. It also creates a backup of the password-protected software keystore before deleting the secret.

```
ADMINISTER KEY MANAGEMENT
  DELETE SECRET FOR CLIENT 'client1'
  IDENTIFIED BY password
  WITH BACKUP;
```

The following statement deletes the secret that was updated in the previous example from a hardware keystore:

```
ADMINISTER KEY MANAGEMENT
  DELETE SECRET FOR CLIENT 'client2'
  IDENTIFIED BY "user_id:password";
```

ALTER ANALYTIC VIEW

Purpose

Use the `ALTER ANALYTIC VIEW` statement to rename or compile an analytic view. Additionally, you can modify grouping level caches by adding or dropping a new level grouping cache to a specifed analytic view.

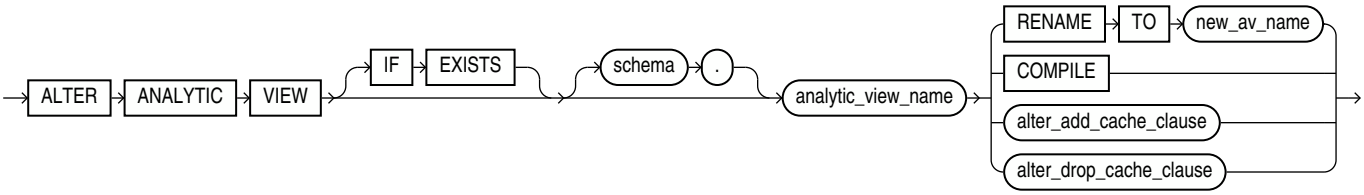
For other alterations, use `CREATE OR REPLACE ANALYTIC VIEW`.

Prerequisites

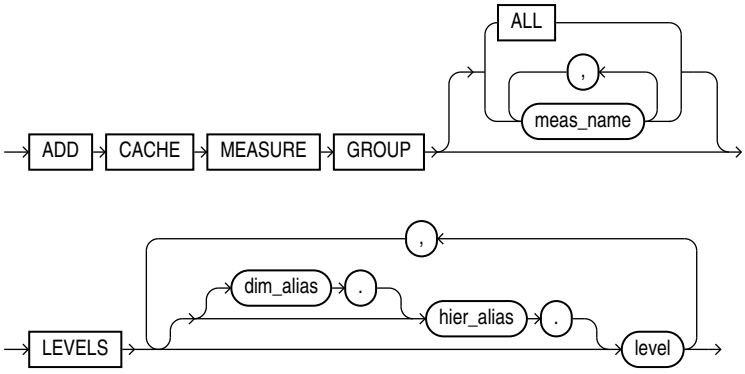
To alter an analytic view in your own schema, you must have the `ALTER ANALYTIC VIEW` system privilege. To alter an analytic view in another user's schema, you must have the `ALTER ANY ANALYTIC VIEW` system privilege or `ALTER ANY TABLE` granted on the analytic view.

Syntax

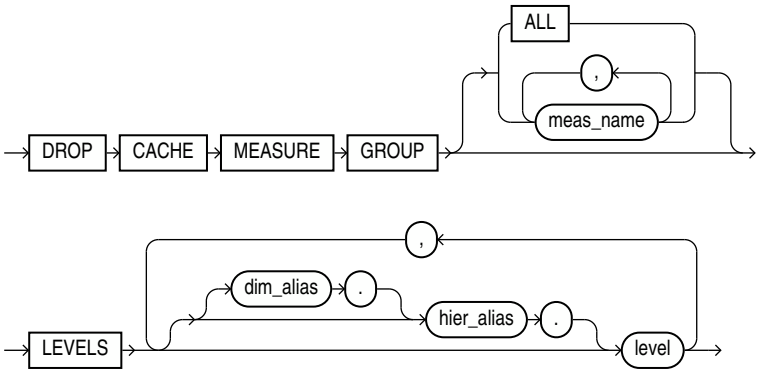
***alter_analytic_view*::=**



***alter_add_cache_clause*::=**



***alter_drop_cache_clause*::=**



Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

schema

Specify the schema in which the analytic view exists. If you do not specify a schema, then Oracle Database looks for the analytic view in your own schema.

analytic_view_name

Specify the name of the analytic view.

RENAME TO

Specify `RENAME TO` to change the name of the analytic view. For *`new_av_name`*, specify a new name for the analytic view.

COMPILE

Specify `COMPILE` to compile the analytic view.

alter_add_cache_clause

Use this clause to add a new level grouping cache to a specified analytic view like the measure group, level clause and the cache type. Before you add a new level grouping cache, you must ensure that it does not match a previously defined cache with the same measures and levels.

alter_drop_cache_clause

Use this clause to drop an existent level grouping cache from an analytic view. You must specify the attributes of the level grouping you are about to drop, like the measure group and the level clause.

Example: Change the Name of an Analytic View

```
ALTER ANALYTIC VIEW sales_av RENAME TO mysales_av;
```

Example: Add a New Level Grouping Cache to an Analytic View

```
ALTER ANALYTIC VIEW TKHCSGL308_UNITS_AVIEW_CACHE ADD CACHE
    MEASURE GROUP (sales, units, cost)
    LEVELS (TIME.FISCAL.FISCAL_QUARTER, WAREHOUSE);
```

ALTER ATTRIBUTE DIMENSION

Purpose

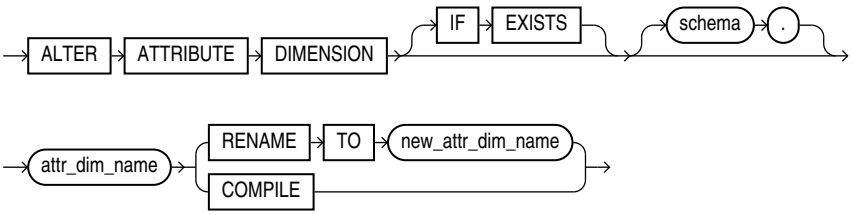
Use the `ALTER ATTRIBUTE DIMENSION` statement to rename or compile an attribute dimension. For other alterations, use `CREATE OR REPLACE ATTRIBUTE DIMENSION`.

Prerequisites

To alter an attribute dimension in your own schema, you must have the `ALTER ATTRIBUTE DIMENSION` system privilege. To alter an attribute dimension in another user's schema, you must have the `ALTER ANY ATTRIBUTE DIMENSION` system privilege or have been granted `ALTER` on the attribute dimension directly.

Syntax

***alter_attribute_dimension*::=**



Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

schema

Specify the schema in which the attribute dimension exists. If you do not specify a schema, then Oracle Database looks for the attribute dimension in your own schema.

attr_dim_name

Specify the name of the attribute dimension.

RENAME TO

Specify `RENAME TO` to change the name of the attribute dimension. For *`new_attr_dim_name`*, specify a new name for the attribute dimension.

COMPILE

Specify `COMPILE` to compile the attribute dimension.

Example

The following statement changes the name of an attribute dimension:

```
ALTER ATTRIBUTE DIMENSION product_attr_dim RENAME TO my_product_attr_dim;
```

ALTER AUDIT POLICY (Unified Auditing)

This section describes the `ALTER AUDIT POLICY` statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12*c* and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

Purpose

Use the `ALTER AUDIT POLICY` statement to modify a unified audit policy.

> **See Also:**
>
> - CREATE AUDIT POLICY (Unified Auditing)
> - DROP AUDIT POLICY (Unified Auditing)
> - AUDIT (Unified Auditing)
> - NOAUDIT (Unified Auditing)

Prerequisites

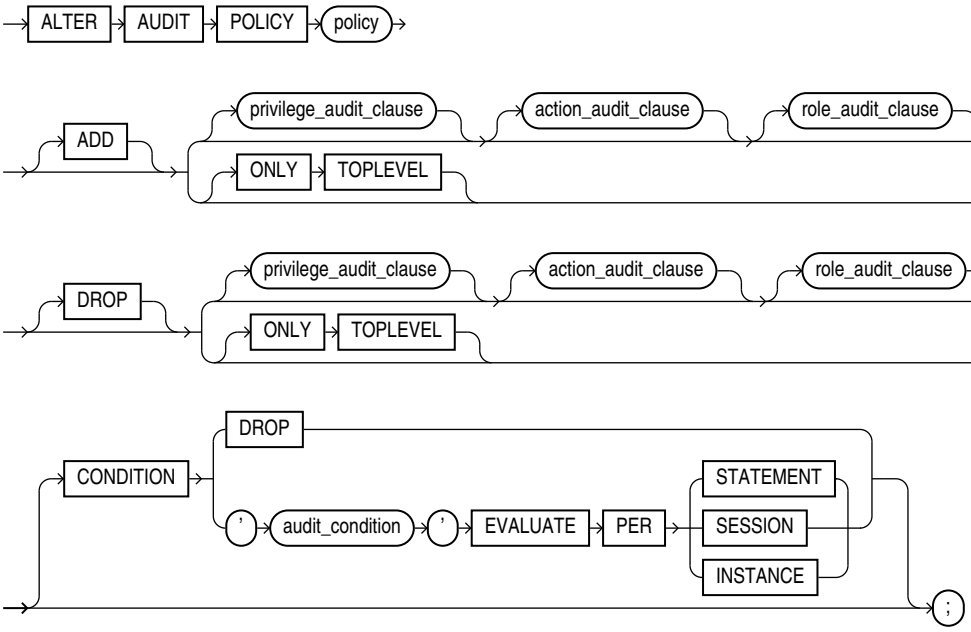
You must have the `AUDIT SYSTEM` system privilege or the `AUDIT_ADMIN` role.

If you are connected to a multitenant container database (CDB), then to modify a common unified audit policy, the current container must be the root and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role. To modify a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role, or you must have the locally granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` local role in the container.

After you alter an unified audit policy with object audit options, the new audit settings take place immediately, for both the active and subsequent user sessions. If you alter an unified audit policy with system audit options, or audit conditions, then they become effective only for new user sessions, but not for the current user session.

Syntax

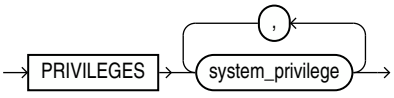
***alter_audit_policy*::=**



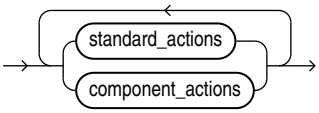
> **Note:**
>
> If you specify the `ADD` or `DROP` clause, then you must specify at least one of the clauses *`privilege_audit_clause`*, *`action_audit_clause`*, or *`role_audit_clause`*.

(*privilege_audit_clause*::=, *action_audit_clause*::=, *role_audit_clause*::=)

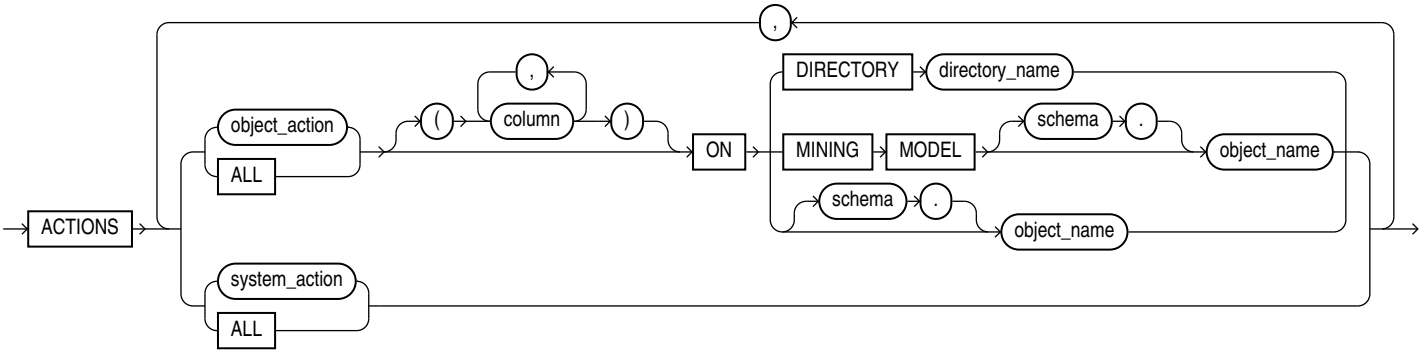
***privilege_audit_clause*::=**



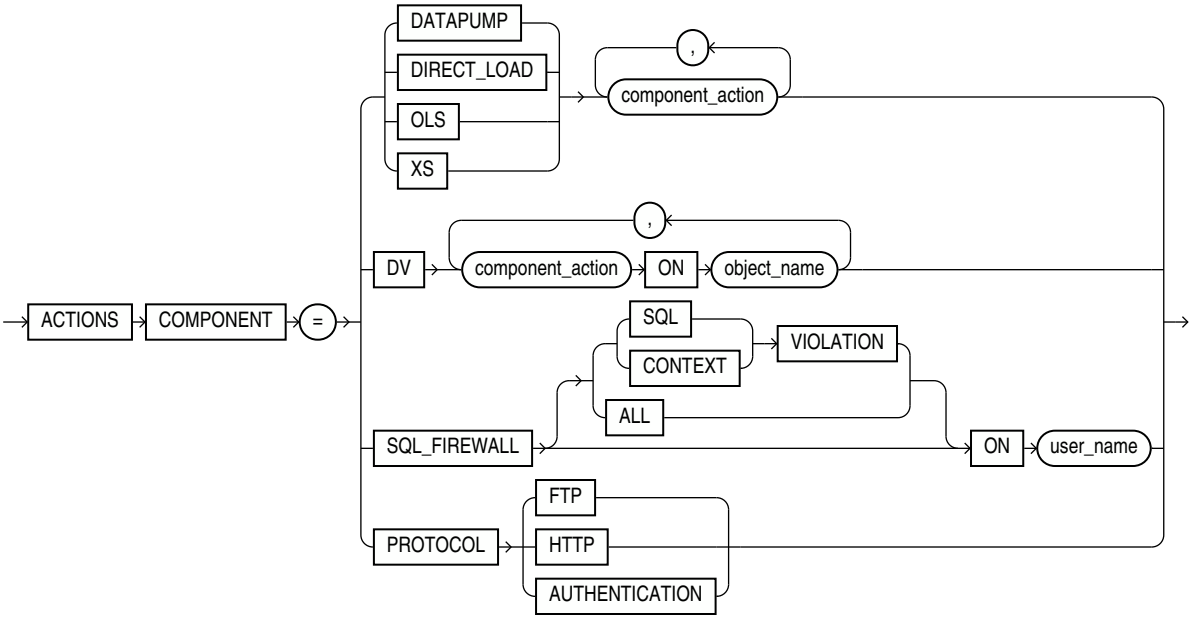
***action_audit_clause*::=**



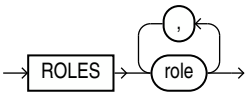
***standard_actions*::=**



***component_actions*::=**



***role_audit_clause*::=**



Semantics

policy

Specify the name of the unified audit policy to be modified. The policy must have been created using the `CREATE AUDIT POLICY` statement. You can find descriptions of all unified audit policies by querying the `AUDIT_UNIFIED_POLICIES` view.

> **See Also:**
>
> - CREATE AUDIT POLICY (Unified Auditing)
> - *Oracle Database Reference* for more information on the `AUDIT_UNIFIED_POLICIES` view

ADD | DROP

Use the `ADD` clause to add privileges to be audited to *`policy`*.

Use the `DROP` clause to remove privileges to be audited from *`policy`*.

Refer to *privilege_audit_clause*, *action_audit_clause*, and *role_audit_clause* of `CREATE AUDIT POLICY` for the full semantics of these clauses.

CONDITION

Use this clause to drop, add, or replace the audit condition for *`policy`*.

Specify `DROP` to drop the audit condition from *`policy`*.

Specify `'audit_condition' ...` to add or replace the audit condition for *`policy`*.

Refer to audit_condition, EVALUATE PER STATEMENT, EVALUATE PER SESSION, and EVALUATE PER INSTANCE of `CREATE AUDIT POLICY` for the full semantics of these clauses.

ONLY TOPLEVEL

Specify this clause to change the existing unified audit policy to audit only the top level SQL statements issued by the user.

Example: Add Top Level Auditing

The example changes the HR audit policy *`hr_audit_policy`* to capture only top level statements.

```
ALTER AUDIT POLICY hr_audit_policy ADD ONLY TOPLEVEL
```

You can drop top level auditing from an existing audit policy auditing the top level SQL statements.

Example: Drop Top Level Auditing

```
ALTER AUDIT POLICY hr_audit_policy DROP ONLY TOPLEVEL
```

See *Database Security Guide* for more information.

Examples

The following examples modify unified audit policies that were created in the `CREATE AUDIT POLICY` "Examples".

Adding Privileges, Actions, and Roles to a Unified Audit Policy: Examples

The following statement adds the system privileges `CREATE ANY TABLE` and `DROP ANY TABLE` to unified audit policy `dml_pol`:

```
ALTER AUDIT POLICY dml_pol
  ADD PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE;
```

The following statement adds the system actions `CREATE JAVA`, `ALTER JAVA`, and `DROP JAVA` to unified audit policy `java_pol`:

```
ALTER AUDIT POLICY java_pol
  ADD ACTIONS CREATE JAVA, ALTER JAVA, DROP JAVA;
```

The following statement adds the role `dba` to unified audit policy `table_pol`:

```
ALTER AUDIT POLICY table_pol
  ADD ROLES dba;
```

The following statement adds multiple system privileges, actions, and roles to unified audit policy `security_pol`:

```
ALTER AUDIT POLICY security_pol
  ADD PRIVILEGES CREATE ANY LIBRARY, DROP ANY LIBRARY
      ACTIONS DELETE on hr.employees,
              INSERT on hr.employees,
              UPDATE on hr.employees,
              ALL on hr.departments
      ROLES dba, connect;
```

Dropping Privileges, Actions, and Roles from a Unified Audit Policy: Examples

The following statement drops the system privilege `CREATE ANY TABLE` from unified audit policy `table_pol`:

```
ALTER AUDIT POLICY table_pol
  DROP PRIVILEGES CREATE ANY TABLE;
```

The following statement drops the `INSERT` and `UPDATE` actions on `hr.employees` from unified audit policy `dml_pol`:

```
ALTER AUDIT POLICY dml_pol
  DROP ACTIONS INSERT on hr.employees,
               UPDATE on hr.employees;
```

The following statement drops the role `java_deploy` from unified audit policy `java_pol`:

```
ALTER AUDIT POLICY java_pol
  DROP ROLES java_deploy;
```

The following statement drops a system privilege, an action, and a role from unified audit policy `hr_admin_pol`:

```
ALTER AUDIT POLICY hr_admin_pol
  DROP PRIVILEGES CREATE ANY TABLE
       ACTIONS LOCK TABLE
       ROLES audit_viewer;
```

Adding and Dropping Actions for a Unified Audit Policy: Example

The following statement adds `EXPORT` actions for Oracle Data Pump to unified audit policy `dp_actions_pol` and drops `IMPORT` actions for Oracle Data Pump:

```
ALTER AUDIT POLICY dp_actions_pol
  ADD ACTIONS COMPONENT = datapump EXPORT
  DROP ACTIONS COMPONENT = datapump IMPORT;
```

Dropping the Audit Condition from a Unified Audit Policy: Example

The following statement drops the audit condition from unified audit policy `order_updates_pol`:

```
ALTER AUDIT POLICY order_updates_pol
  CONDITION DROP;
```

Modifying the Audit Condition for a Unified Audit Policy: Example

The following statement modifies the audit condition for unified audit policy `emp_updates_pol` so that the policy is enforced only when the auditable statement is issued by a user whose UID is 102:

```
ALTER AUDIT POLICY emp_updates_pol
  CONDITION 'UID = 102'
  EVALUATE PER STATEMENT;
```

Altering an Audit Policy at the Column Level: Example

The audit policy `employee_audit_policy` generates audit records only when the select operation is performed on the `sal` column in the `emp` table.

```
CREATE AUDIT POLICY employee_audit_policy ACTIONS SELECT(sal) on scott.emp;
```

The example alters the `employee_audit_policy` so that audit records are generated also when insert operations are done in the `dname` column of the `dept` table.

```
ALTER AUDIT POLICY employee_audit_policy ACTIONS ADD INSERT(dname) on scott.dept;
```

ALTER CLUSTER

Purpose

Use the `ALTER CLUSTER` statement to redefine storage and parallelism characteristics of a cluster.

> **Note:**
>
> You cannot use this statement to change the number or the name of columns in the cluster key, and you cannot change the tablespace in which the cluster is stored.

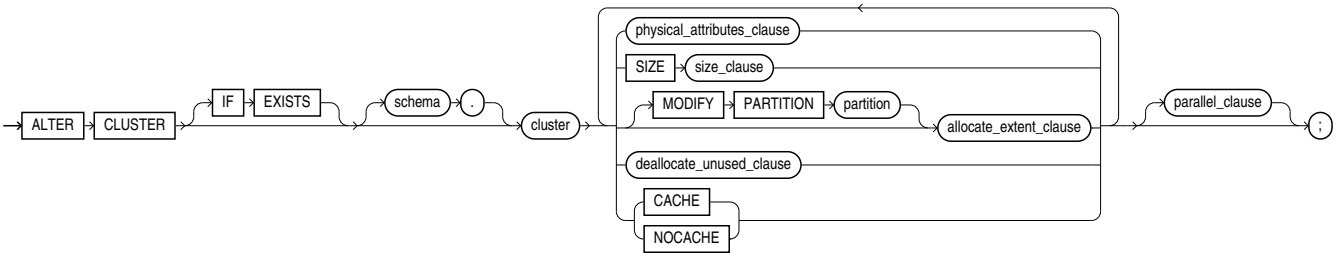
> **See Also:**
>
> CREATE CLUSTER for information on creating a cluster, DROP CLUSTER and DROP TABLE for information on removing tables from a cluster, and CREATE TABLE ... *physical_properties* for information on adding a table to a cluster

Prerequisites

The cluster must be in your own schema or you must have the `ALTER ANY CLUSTER` system privilege.

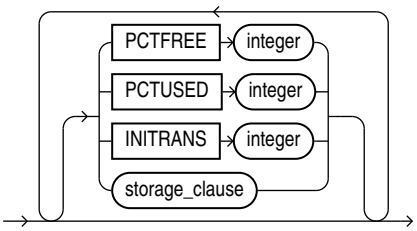
Syntax

***alter_cluster*::=**



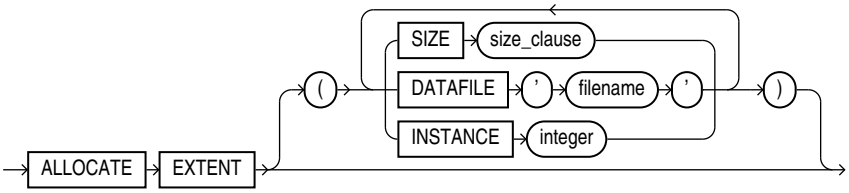
(*physical_attributes_clause*::, *size_clause*::=, MODIFY PARTITION, *allocate_extent_clause*::=, *deallocate_unused_clause*::=, *parallel_clause*::=)

***physical_attributes_clause*::**



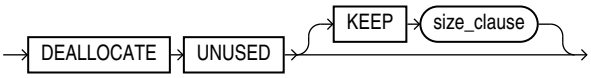
(*storage_clause*::=)

***allocate_extent_clause*::=**



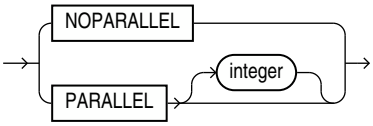
(*size_clause*::=)

***deallocate_unused_clause*::=**



(*size_clause*::=)

***parallel_clause*::=**



Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

schema

Specify the schema containing the cluster. If you omit *schema*, then Oracle Database assumes the cluster is in your own schema.

cluster

Specify the name of the cluster to be altered.

physical_attributes_clause

Use this clause to change the values of the `PCTUSED`, `PCTFREE`, and `INITRANS` parameters of the cluster.

Use the `STORAGE` clause to change the storage characteristics of the cluster.

> **See Also:**
>
> - *physical_attributes_clause* for information on the parameters
> - storage_clause for a full description of that clause

Restriction on Physical Attributes

You cannot change the values of the storage parameters `INITIAL` and `MINEXTENTS` for a cluster.

SIZE

integer

Use the `SIZE` clause to specify the number of cluster keys that will be stored in data blocks allocated to the cluster.

Restriction on SIZE

You can change the `SIZE` parameter only for an indexed cluster, not for a hash cluster.

> **See Also:**
>
> CREATE CLUSTER for a description of the `SIZE` parameter and "Modifying a Cluster: Example"

MODIFY PARTITION

Specify `MODIFY PARTITION` *`partition allocate_extent_clause`* to explicitly allocate a new extent for a cluster partition. This operation is valid only for range-partitioned hash clusters. For *`partition`*, specify the cluster partition name.

allocate_extent_clause

Specify *`allocate_extent_clause`* to explicitly allocate a new extent for a cluster. This operation is valid only for indexed clusters and nonpartitioned hash clusters.

When you explicitly allocate an extent with the *`allocate_extent_clause`*, Oracle Database does not evaluate the storage parameters of the cluster and determine a new size for the next extent to be allocated (as it does when you create a table). Therefore, specify `SIZE` if you do not want Oracle Database to use a default value.

> **See Also:**
>
> *allocate_extent_clause* for a full description of this clause

deallocate_unused_clause

Use the *`deallocate_unused_clause`* to explicitly deallocate unused space at the end of the cluster and make the freed space available for other segments.

> **See Also:**
>
> *deallocate_unused_clause* for a full description of this clause and "Deallocating Unused Space: Example"

parallel_clause

Specify the *`parallel_clause`* to change the default degree of parallelism for queries on the cluster.

> **See Also:**
>
> *parallel_clause* in the documentation on `CREATE TABLE` for complete information on this clause

Examples

The following examples modify the clusters that were created in the `CREATE CLUSTER` "Examples".

Modifying a Cluster: Example

The next statement alters the `personnel` cluster:

```
ALTER CLUSTER personnel
   SIZE 1024 CACHE;
```

Oracle Database allocates 1024 bytes for each cluster key value and enables the cache attribute. Assuming a data block size of 2 kilobytes, future data blocks within this cluster contain 2 cluster keys in each data block, or 2 kilobytes divided by 1024 bytes.

Deallocating Unused Space: Example

The following statement deallocates unused space from the `language` cluster, keeping 30 kilobytes of unused space for future use:

```
ALTER CLUSTER language
   DEALLOCATE UNUSED KEEP 30 K;
```

Altering Clusters: Example

The following statement creates a cluster with the default key size (600):

```
CREATE CLUSTER EMP_DEPT (DEPTNO NUMBER(3))
   SIZE 600
   TABLESPACE USERS
   STORAGE (INITIAL 200K
      NEXT 300K
      MINEXTENTS 2
      PCTINCREASE 33);
```

The following statement queries `USER_CLUSTERS` to display the cluster metadata:

```
SELECT CLUSTER_NAME, TABLESPACE_NAME, KEY_SIZE, CLUSTER_TYPE,
AVG_BLOCKS_PER_KEY, MIN_EXTENTS, MAX_EXTENTS FROM USER_CLUSTERS;

CLUSTER_NAME    TABLESPACE_NAME                  KEY_SIZE CLUST
AVG_BLOCKS_PER_KEY MIN_EXTENTS MAX_EXTENTS
-------------- ------------------------------ ---------- -----
----------------- ----------- -----------
EMP_DEPT        USERS                                600
INDEX                             1  2147483645
```

The following statement modifies the cluster key size:

```
ALTER CLUSTER EMP_DEPT SIZE 1024;
```

The following statement displays the metadata of the modified cluster:

```
SELECT CLUSTER_NAME, TABLESPACE_NAME, KEY_SIZE, CLUSTER_TYPE,
AVG_BLOCKS_PER_KEY, MIN_EXTENTS, MAX_EXTENTS FROM USER_CLUSTERS;
```

```
CLUSTER_NAME    TABLESPACE_NAME                   KEY_SIZE CLUST
AVG_BLOCKS_PER_KEY MIN_EXTENTS MAX_EXTENTS
--------------- ------------------------------ ---------- -----
----------------- ----------- -----------
EMP_DEPT        USERS                               1024
INDEX                            1  2147483645
```

The following statement deallocates unused space from the `EMP_DEPT` cluster, keeping 30 kilobytes of unused space for future use:

```
ALTER CLUSTER EMP_DEPT DEALLOCATE UNUSED KEEP 30 K;
```

The following statement displays the metadata of the modified cluster:

```
SELECT CLUSTER_NAME, TABLESPACE_NAME, KEY_SIZE, CLUSTER_TYPE,
AVG_BLOCKS_PER_KEY, MIN_EXTENTS, MAX_EXTENTS FROM USER_CLUSTERS;

CLUSTER_NAME    TABLESPACE_NAME                   KEY_SIZE CLUST
AVG_BLOCKS_PER_KEY MIN_EXTENTS MAX_EXTENTS
--------------- ------------------------------ ---------- -----
----------------- ----------- -----------
EMP_DEPT        USERS                               1024
INDEX                            1  2147483645
```

ALTER DATABASE

Purpose

Use the `ALTER DATABASE` statement to modify, maintain, or recover an existing database.

See Also:

- *Oracle Database Backup and Recovery User's Guide* for examples of performing media recovery
- *Oracle Data Guard Concepts and Administration* for additional information on using the `ALTER DATABASE` statement to maintain standby databases
- CREATE DATABASE for information on creating a database

Prerequisites

You must have the `ALTER DATABASE` system privilege.

To specify the *startup_clauses*, you must also be connected AS SYSDBA, AS SYSOPER, AS SYSBACKUP, or AS SYSDG.

To specify the *general_recovery* clause, you must also have the SYSDBA or SYSBACKUP system privilege.

To specify the DEFAULT EDITION clause, you must also have the USE object privilege WITH GRANT OPTION on the specified edition.

If you are connected to a multitenant container database (CDB):

- To modify the entire CDB, the current container must be the root and you must have the commonly granted ALTER DATABASE privilege.
- To modify a container, it must be the current container and you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the container.

Notes on Using ALTER DATABASE in a CDB

When you issue the ALTER DATABASE statement while connected to a CDB, the behavior of the statement depends on the current container and the clause(s) you specify.

If the current container is the root, then ALTER DATABASE statements with the following clauses modify the entire CDB. In order to specify these clauses, you must have the commonly granted ALTER DATABASE privilege:

- *startup_clauses*
- *recovery_clauses*

  Note: A subset of the *recovery_clauses* are supported to back up and recover an individual pluggable database (PDB). In order to specify these clauses, you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the PDB. Refer to "Notes on Using the recovery_clauses in a CDB" for more information.
- *logfile_clauses*
- *controlfile_clauses*
- *standby_database_clauses*
- *instance_clauses*
- *security_clause*
- RENAME GLOBAL_NAME TO
- ENABLE BLOCK CHANGE TRACKING
- DISABLE BLOCK CHANGE TRACKING
- *undo_mode_clause*

If the current container is the root, then ALTER DATABASE statements with the following clauses modify only the root. In order to specify these clauses, you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the root:

- *database_file_clauses*
- DEFAULT EDITION
- DEFAULT TABLESPACE

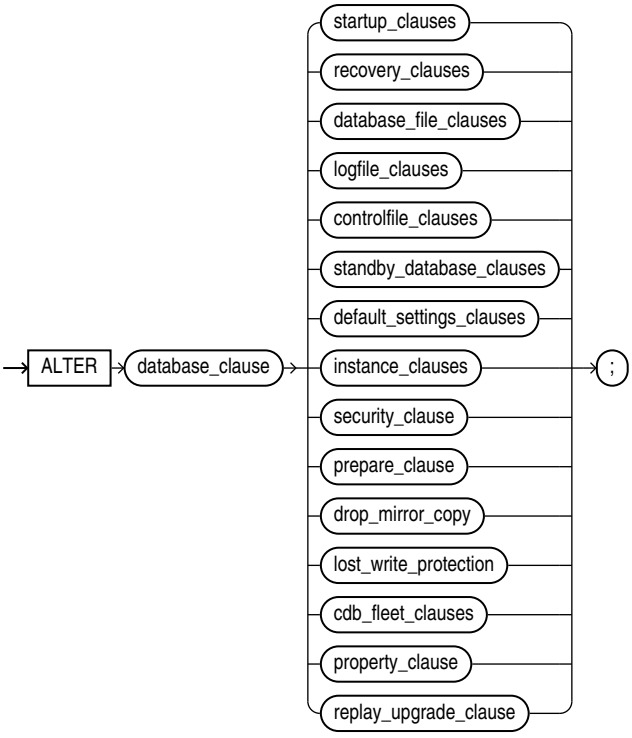
If the current container is the root, then `ALTER DATABASE` statements with the following clauses modify the root and set default values for the PDBs. In order to specify these clauses, you must have the commonly granted `ALTER DATABASE` privilege:

- `DEFAULT [ LOCAL ] TEMPORARY TABLESPACE`
- *`flashback_mode_clause`*
- `SET DEFAULT { BIGFILE | SMALLFILE } TABLESPACE`
- *`set_time_zone_clause`*

If the current container is a PDB, then `ALTER DATABASE` statements modify that PDB. In this case, you can issue only `ALTER DATABASE` clauses that are also supported by the `ALTER PLUGGABLE DATABASE` statement. This functionality is provided to maintain backward compatibility for applications that have been migrated to a CDB environment. The exception is modifying PDB storage limits, for which you must use the *`pdb_storage_clause`* of `ALTER PLUGGABLE DATABASE`. Refer to the documentation on ALTER PLUGGABLE DATABASE for complete information on these clauses.

Syntax

***alter_database*::=**



Groups of ALTER DATABASE syntax:

- ***startup_clauses*::=**

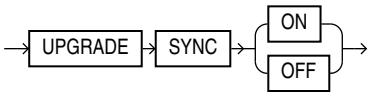
property_clause

***replay_upgrade_clause*::=**



Semantics

database_clause

Specify the `DATABASE` option for a non-container database.

db_name

Specify the name of the database to be altered. If you omit *`db_name`*, then Oracle Database alters the database identified by the value of the initialization parameter `DB_NAME`. You can alter only the database whose control files are specified by the initialization parameter `CONTROL_FILES`. The database identifier is not related to the Oracle Net database specification.

startup_clauses

The *`startup_clauses`* let you mount and open the database so that it is accessible to users.

MOUNT Clause

Use the `MOUNT` clause to mount the database. Do not use this clause when the database is already mounted.

MOUNT STANDBY DATABASE

You can specify `MOUNT STANDBY DATABASE` to mount a physical standby database. The keywords `STANDBY DATABASE` are optional, because Oracle Database determines automatically whether

the database to be mounted is a primary or standby database. As soon as this statement executes, the standby instance can receive redo data from the primary instance.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information on standby databases

MOUNT CLONE DATABASE

Specify `MOUNT CLONE DATABASE` to mount the clone database.

OPEN Clause

Use the `OPEN` clause to make the database available for normal use. You must mount the database before you can open it.

If you specify only `OPEN` without any other keywords, then the default is `OPEN READ WRITE NORESETLOGS` on a primary database, logical standby database, or snapshot standby database and `OPEN READ ONLY` on a physical standby database.

OPEN READ WRITE

Specify `OPEN READ WRITE` to open the database in read/write mode, allowing users to generate redo logs. This is the default if you are opening a primary database. You cannot specify this clause for a physical standby database.

> **See Also:**
>
> "READ ONLY / READ WRITE: Example"

RESETLOGS | NORESETLOGS

This clause determines whether Oracle Database resets the current log sequence number to 1, archives any unarchived logs (including the current log), and discards any redo information that was not applied during recovery, ensuring that it will never be applied. Oracle Database uses `NORESETLOGS` automatically except in the following specific situations, which require a setting for this clause:

- You must specify `RESETLOGS`:
  - After performing incomplete media recovery or media recovery using a backup control file
  - After a previous `OPEN RESETLOGS` operation that did not complete
  - After a `FLASHBACK DATABASE` operation
- If a created control file is mounted, then you must specify `RESETLOGS` if the online logs are lost, or you must specify `NORESETLOGS` if they are not lost.

UPGRADE | DOWNGRADE

Use these `OPEN` clause parameters only if you are upgrading or downgrading a database. This clause instructs Oracle Database to modify system parameters dynamically as required for

upgrade and downgrade, respectively. You can achieve the same result using the SQL*Plus `STARTUP UPGRADE` or `STARTUP DOWNGRADE` command.

When you use the `UPGRADE` or `DOWNGRADE` parameters for a CDB, the root container is opened in the specified mode, but all other containers are opened in `READ WRITE` mode.

> **See Also:**
>
> - *Oracle Database Upgrade Guide* for information on the steps required to upgrade or downgrade a database from one release to another
> - *SQL*Plus User's Guide and Reference* for information on the SQL*Plus `STARTUP` command

OPEN READ ONLY

Specify `OPEN READ ONLY` to restrict users to read-only transactions, preventing them from generating redo logs. This setting is the default when you are opening a physical standby database, so that the physical standby database is available for queries even while archive logs are being copied from the primary database site.

Restrictions on Opening a Database

The following restrictions apply to opening a database:

- You cannot open a database in `READ ONLY` mode if it is currently opened in `READ WRITE` mode by another instance.
- You cannot open a database in `READ ONLY` mode if it requires recovery.
- You cannot take tablespaces offline while the database is open in `READ ONLY` mode. However, you can take data files offline and online, and you can recover offline data files and tablespaces while the database is open in `READ ONLY` mode.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for additional information about opening a physical standby database

recovery_clauses

The *`recovery_clauses`* include post-backup operations. For all of these clauses, Oracle Database recovers the database using any incarnations of data files and log files that are known to the current control file.

> **See Also:**
>
> *Oracle Database Backup and Recovery User's Guide* for information on backing up the database and "Database Recovery: Examples"

Notes on Using the *recovery_clauses* in a CDB

When the current container is the root, you can specify all of the *recovery_clauses* to back up and recover the entire CDB.

When the current container is a PDB, you can specify the following subclauses of the *recovery_clauses* to back up and recover the PDB:

- BEGIN BACKUP
- END BACKUP
- *full_database_recovery*: You can specify only the DATABASE keyword
- *partial_database_recovery*
- The LOGFILE and CONTINUE clauses of *general_recovery*

You can also specify the preceding subclauses using the *pdb_recovery_clauses* of ALTER PLUGGABLE DATABASE. Refer to the syntax diagram *pdb_recovery_clauses* of ALTER PLUGGABLE DATABASE.

general_recovery

The *general_recovery* clause lets you control media recovery for the database or standby database or for specified tablespaces or files. You can use this clause when your instance has the database mounted, open or closed, and the files involved are not in use.

> **Note:**
>
> Parallelism is enabled by default during full or partial database recovery and logfile recovery. The database computes the degree of parallelism. You can disable parallelism of these operations by specifying NOPARALLEL, or specify a degree of parallelism with PARALLEL *integer*, as shown in the respective syntax diagrams.

Restrictions on General Database Recovery

General recovery is subject to the following restrictions:

- You can recover the entire database only when the database is closed.
- Your instance must have the database mounted in exclusive mode.
- You can recover tablespaces or data files when the database is open or closed, if the tablespaces or data files to be recovered are offline.
- You cannot perform media recovery if you are connected to Oracle Database through the shared server architecture.

> **See Also:**
>
> - *Oracle Database Backup and Recovery User's Guide* for more information on RMAN media recovery and user-defined media recovery
> - *SQL*Plus User's Guide and Reference* for information on the SQL*Plus RECOVER command

AUTOMATIC

Specify AUTOMATIC if you want Oracle Database to automatically generate the name of the next archived redo log file needed to continue the recovery operation. If the LOG_ARCHIVE_DEST_*n* parameters are defined, then Oracle Database scans those that are valid and enabled for the first local destination. It uses that destination in conjunction with LOG_ARCHIVE_FORMAT to generate the target redo log filename. If the LOG_ARCHIVE_DEST_*n* parameters are not defined, then Oracle Database uses the value of the LOG_ARCHIVE_DEST parameter instead.

If the resulting file is found, then Oracle Database applies the redo contained in that file. If the file is not found, then Oracle Database prompts you for a filename, displaying the generated filename as a suggestion.

If you specify neither AUTOMATIC nor LOGFILE, then Oracle Database prompts you for a filename, displaying the generated filename as a suggestion. You can then accept the generated filename or replace it with a fully qualified filename. If you know that the archived filename differs from what Oracle Database would generate, then you can save time by using the LOGFILE clause.

FROM *'location'*

Specify FROM *'location'* to indicate the location from which the archived redo log file group is read. The value of *location* must be a fully specified file location following the conventions of your operating system. If you omit this parameter, then Oracle Database assumes that the archived redo log file group is in the location specified by the initialization parameter LOG_ARCHIVE_DEST or LOG_ARCHIVE_DEST_1.

full_database_recovery

The *full_database_recovery* clause lets you recover an entire database.

DATABASE

Specify the DATABASE clause to recover the entire database. This is the default. You can use this clause only when the database is closed.

STANDBY DATABASE

Specify the STANDBY DATABASE clause to manually recover a physical standby database using the control file and archived redo log files copied from the primary database. The standby database must be mounted but not open.

This clause recovers only online data files.

- Use the UNTIL clause to specify the duration of the recovery operation.
  - CANCEL indicates cancel-based recovery. This clause recovers the database until you issue the ALTER DATABASE statement with the RECOVER CANCEL clause.
  - TIME indicates time-based recovery. This parameter recovers the database to the time specified by the date. The date must be a character literal in the format 'YYYY-MM-DD:HH24:MI:SS'.
  - CHANGE indicates change-based recovery. This parameter recovers the database to a transaction-consistent state immediately before the system change number specified by *integer*.
  - CONSISTENT recovers the database until all online files are brought to a consistent SCN point so that the database can be open in read only mode. This clauses requires the controlfile to be a backup controlfile.
- Specify USING BACKUP CONTROLFILE if you want to use a backup control file instead of the current control file.

- Specify the SNAPSHOT TIME clause to recover the database with a storage snapshot using Storage Snapshot Optimization. This clause can be used in cases where the database was not placed in backup mode when the storage snapshot was created.
  - *date* must be a character literal in the format 'YYYY-MM-DD:HH24:MI:SS'. It must represent a time that is immediately after the snapshot was completed. If you specify the UNTIL TIME clause, then SNAPSHOT TIME *date* must be earlier than UNTIL TIME *date*.

> **See Also:**
>
> *Oracle Database Backup and Recovery User's Guide* for more information on recovery using Storage Snapshot Optimization

partial_database_recovery

The *partial_database_recovery* clause lets you recover individual tablespaces and data files.

TABLESPACE

Specify the TABLESPACE clause to recover only the specified tablespaces. You can use this clause if the database is open or closed, provided the tablespaces to be recovered are offline.

> **See Also:**
>
> "Using Parallel Recovery Processes: Example"

DATAFILE

Specify the DATAFILE clause to recover the specified data files. You can use this clause when the database is open or closed, provided the data files to be recovered are offline.

You can identify the data file by name or by number. If you identify it by number, then *filenumber* is an integer representing the number found in the FILE# column of the V$DATAFILE dynamic performance view or in the FILE_ID column of the DBA_DATA_FILES data dictionary view.

STANDBY {TABLESPACE | DATAFILE}

In earlier releases, you could specify STANDBY TABLESPACE or STANDBY DATAFILE to recover older backups of a specific tablespace or a specific data file on the standby to be consistent with the rest of the standby database. These two clauses are now desupported. Instead, to recover the standby database to a consistent point, but no further, use the statement ALTER DATABASE RECOVER MANAGED STANDBY DATABASE UNTIL CONSISTENT.

LOGFILE

Specify the LOGFILE '*filename*' to continue media recovery by applying the specified redo log file.

TEST

Use the TEST clause to conduct a trial recovery. A trial recovery is useful if a normal recovery procedure has encountered some problem. It lets you look ahead into the redo stream to detect possible additional problems. The trial recovery applies redo in a way similar to normal

recovery, but it does not write changes to disk, and it rolls back its changes at the end of the trial recovery.

You can use this clause only if you have restored a backup taken since the last `RESETLOGS` operation. Otherwise, Oracle Database returns an error.

ALLOW ... CORRUPTION

The `ALLOW` *`integer`* `CORRUPTION` clause lets you specify, in the event of logfile corruption, the number of corrupt blocks that can be tolerated while allowing recovery to proceed.

> **See Also:**
>
> - *Oracle Database Backup and Recovery User's Guide* for information on database recovery in general
> - *Oracle Data Guard Concepts and Administration* for information on managed recovery of standby databases

CONTINUE

Specify `CONTINUE` to continue multi-instance recovery after it has been interrupted to disable a thread.

Specify `CONTINUE DEFAULT` to continue recovery using the redo log file that Oracle Database would automatically generate if no other logfile were specified. This clause is equivalent to specifying `AUTOMATIC`, except that Oracle Database does not prompt for a filename.

CANCEL

Specify `CANCEL` to terminate cancel-based recovery.

managed_standby_recovery

Use the *`managed_standby_recovery`* clause to start and stop Redo Apply on a physical standby database. Redo Apply keeps the standby database transactionally consistent with the primary database by continuously applying redo received from the primary database.

A primary database transmits its redo data to standby sites. As the redo data is written to redo log files at the physical standby site, the log files become available for use by Redo Apply. You can use the *`managed_standby_recovery`* clause when your standby instance has the database mounted or is opened read-only.

> **Note:**
>
> Beginning with Oracle Database 12*c*, **real-time apply** is enabled by default during Redo Apply. Real-time apply recovers redo from the standby redo log files as soon as they are written, without requiring them to be archived first at the physical standby database. You can disable real-time apply with the `USING ARCHIVED LOGFILE` clause. Refer to:
>
> - *Oracle Data Guard Concepts and Administration* for more information on real-time apply
> - USING ARCHIVED LOGFILE Clause

> **Note:**
>
> Parallelism is enabled by default during Redo Apply. The database computes the degree of parallelism. You can disable parallelism of these operations by specifying `NOPARALLEL`, or specify a degree of parallelism with `PARALLEL` *`integer`*, as shown in the respective syntax diagrams.

Restrictions on Managed Standby Recovery

The same restrictions listed under *general_recovery* apply to this clause.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information on the use of this clause

USING ARCHIVED LOGFILE Clause

Specify `USING ARCHIVED LOGFILE` to start Redo Apply without enabling real-time apply.

DISCONNECT

Specify `DISCONNECT` to indicate that Redo Apply should be performed in the background, leaving the current session available for other tasks. The `FROM SESSION` keywords are optional and are provided for semantic clarity.

NODELAY

The `NODELAY` clause overrides the `DELAY` attribute on the `LOG_ARCHIVE_DEST_n` parameter on the primary database. If you do not specify the `NODELAY` clause, then application of the archived redo log file is delayed according to the `DELAY` attribute of the `LOG_ARCHIVE_DEST_`*`n`* setting (if any). If the `DELAY` attribute was not specified on that parameter, then the archived redo log file is applied immediately to the standby database.

If you specify real-time apply with the `USING CURRENT LOGFILE` clause, then any `DELAY` value specified for the `LOG_ARCHIVE_DEST_`*`n`* parameter at the primary for this standby is ignored, and `NODELAY` is the default.

UNTIL CHANGE Clause

Use this clause to instruct Redo Apply to recover redo data up to, but not including, the specified system change number.

UNTIL CONSISTENT

Use this clause to recover the standby database to a consistent SCN point so that the standby database can be opened in read only mode.

USING INSTANCES

This clause is applicable only for Oracle Real Application Clusters (Oracle RAC) or Oracle RAC One Node databases and allows you to start apply processes on multiple instances of the standby that are started in the same mode (`MOUNTED` or `READ ONLY`) as the instance on which the command is executed. Specify `USING INSTANCES ALL` to perform Redo Apply on all instances in an Oracle RAC standby database started in the same mode. Specify `USING INSTANCES` *`integer`* to perform Redo Apply on the specified number of instances that are started in the same mode. For *`integer`*, specify an integer value from 1 to the number of instances in the standby database. The database chooses the instances on which to perform Redo Apply; you cannot specify particular instances. For example, if you specify 4 instances from an instance that is `MOUNTED` and only 3 instances of the standby are running in the `MOUNTED` mode, then Redo Apply will only be started on 3 instances. If you omit the `USING INSTANCES` clause, then Oracle Database performs Redo Apply only on the instance where the command was executed.

FINISH

Specify `FINISH` to complete applying all available redo data in preparation for a failover.

Use the `FINISH` clause only in the event of the failure of the primary database. This clause overrides any specified delay intervals and applies all available redo immediately. After the `FINISH` command completes, this database can no longer run in the standby database role, and it must be converted to a primary database by issuing the `ALTER DATABASE COMMIT TO SWITCHOVER TO PRIMARY` statement.

CANCEL

Specify `CANCEL` to stop Redo Apply immediately. Control is returned as soon as Redo Apply stops.

TO LOGICAL STANDBY Clause

Use this clause to convert a physical standby database into a logical standby database.

db_name

Specify a database name to identify the new logical standby database. If you are using a server parameter file (spfile) at the time you issue this statement, then the database will update the file with appropriate information about the new logical standby database. If you are not using an spfile, then the database issues a message reminding you to set the name of the `DB_NAME` parameter after shutting down the database. In addition, you must invoke the `DBMS_LOGSTDBY.BUILD` PL/SQL procedure on the primary database before using this clause on the standby database.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_LOGSTDBY.BUILD` procedure

KEEP IDENTITY

Use this clause if you want to use the rolling upgrade feature provided by a logical standby and also revert to the original configuration of a primary database and a physical standby. A logical standby database created using this clause provides only limited support for switchover and failover. Therefore, do not use this clause create a general-purpose logical standby database.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information on rolling upgrade

Deprecated Managed Standby Recovery Clauses

The following clauses appeared in the syntax of earlier releases. They have been deprecated and are no longer needed. Oracle recommends that you do not use these clauses.

FINISH FORCE, FINISH WAIT, FINISH NOWAIT

These optional forms of the `FINISH` clause are deprecated. Their semantics are presented here for backward compatibility:

- `FORCE` terminates inactive redo transport sessions that would otherwise prevent `FINISH` processing from beginning.
- `NOWAIT` returns control to the foreground process before the recovery completes
- `WAIT` (the default) returns control to the foreground process after recovery completes

When specified, these clauses are ignored. Terminal recovery now runs in the foreground and always terminates all redo transport sessions. Therefore control is not returned to the user until recovery completes.

CANCEL IMMEDIATE, CANCEL WAIT, CANCEL NOWAIT

These optional forms of the `CANCEL` clause are deprecated. Their semantics are presented here for backward compatibility:

- Include the `IMMEDIATE` keyword to stop Redo Apply *before* completely applying the current redo log file. Session control returns when Redo Apply actually stops.
- Include the `NOWAIT` keyword to return session control without waiting for the `CANCEL` operation to complete.

When specified, these clauses are ignored. Redo Apply is now always cancelled immediately and control returns to the session only after the operation completes.

USING CURRENT LOGFILE Clause

The `USING CURRENT LOGFILE` clause is deprecated. It invokes real-time apply during Redo Apply. However, this is now the default behavior and this clause is no longer useful.

BACKUP Clauses

Use these clauses to move all the data files in the database into or out of online backup mode (also called hot backup mode).

> **See Also:**
>
> ALTER TABLESPACE for information on moving all data files in an individual tablespace into and out of online backup mode

BEGIN BACKUP Clause

Specify `BEGIN BACKUP` to move all data files in the database into online backup mode. The database must be mounted and open, and media recovery must be enabled (the database must be in `ARCHIVELOG` mode).

While the database is in online backup mode, you cannot shut down the instance normally, begin backup of an individual tablespace, or take any tablespace offline or make it read only.

This clause has no effect on data files that are in offline or on read-only tablespaces.

END BACKUP Clause

Specify `END BACKUP` to take out of online backup mode any data files in the database currently in online backup mode. The database must be mounted (either open or closed) when you perform this operation.

After a system failure, instance failure, or `SHUTDOWN ABORT` operation, Oracle Database does not know whether the files in online backup mode match the files at the time the system crashed. If you know the files are consistent, then you can take either individual data files or all data files out of online backup mode. Doing so avoids media recovery of the files upon startup.

- To take an individual data file out of online backup mode, use the `ALTER DATABASE DATAFILE ... END BACKUP` statement. See *database_file_clauses* .
- To take all data files in a tablespace out of online backup mode, use an `ALTER TABLESPACE ... END BACKUP` statement.

database_file_clauses

The *`database_file_clauses`* let you modify data files and temp files. You can use any of the following clauses when your instance has the database mounted, open or closed, and the files involved are not in use. The exception is the *`move_datafile_clause`*, which allows you to move a data file that is in use.

RENAME FILE Clause

Use the `RENAME FILE` clause to rename data files, temp files, or redo log file members. You must create each filename using the conventions for filenames on your operating system before specifying this clause.

- To use this clause for a data file or temp file, the database must be mounted. The database can also be open, but the data file or temp file being renamed must be offline. In addition, you must first rename the file on the file system to the new name.
- To use this clause for logfiles, the database must be mounted but not open.

- If you have enabled block change tracking, then you can use this clause to rename the block change tracking file. The database must be mounted but not open when you rename the block change tracking file.

This clause renames only files in the control file. It does not actually rename them on your operating system. The operating system files continue to exist, but Oracle Database no longer uses them.

> **See Also:**
>
> - *Oracle Database Backup and Recovery User's Guide* for information on recovery of data files and temp files
> - "Renaming a Log File Member: Example" and "Manipulating Temp Files: Example"

create_datafile_clause

Use the `CREATE DATAFILE` clause to create a new empty data file in place of an old one. You can use this clause to re-create a data file that was lost with no backup. The *`filename`* or *`filenumber`* must identify a file that is or was once part of the database. If you identify the file by number, then *`filenumber`* is an integer representing the number found in the `FILE#` column of the `V$DATAFILE` dynamic performance view or in the `FILE_ID` column of the `DBA_DATA_FILES` data dictionary view.

- Specify `AS NEW` to create an Oracle-managed data file with a system-generated filename, the same size as the file being replaced, in the default file system location for data files.
- Specify `AS` *`file_specification`* to assign a file name (and optional size) to the new data file. Use the *`datafile_tempfile_spec`* form of *`file_specification`* (see *file_specification*) to list regular data files and temp files in an operating system file system or to list Oracle Automatic Storage Management (Oracle ASM) disk group files.

If the original file (*`filename`* or *`filenumber`*) is an existing Oracle-managed data file, then Oracle Database attempts to delete the original file after creating the new file. If the original file is an existing user-managed data file, then Oracle Database does not attempt to delete the original file.

If you omit the `AS` clause entirely, then Oracle Database creates the new file with the same name and size as the file specified by *`filename`* or *`filenumber`*.

During recovery, all archived redo logs written to since the original data file was created must be applied to the new, empty version of the lost data file.

Oracle Database creates the new file in the same state as the old file when it was created. You must perform media recovery on the new file to return it to the state of the old file at the time it was lost.

Restrictions on Creating New Data Files

The creation of new data files is subject to the following restrictions:

- You cannot create a new file based on the first data file of the `SYSTEM` tablespace.
- You cannot specify the *`autoextend_clause`* of *`datafile_tempfile_spec`* in this `CREATE DATAFILE` clause.

> **See Also:**
>
> - "DATAFILE Clause" of `CREATE DATABASE` for information on the result of this clause if you do not specify a name for the new data file
> - *file_specification* for a full description of the file specification (*datafile_tempfile_spec*) and "Creating a New Data File: Example"

alter_datafile_clause

The `DATAFILE` clause lets you manipulate a file that you identify by name or by number. If you identify it by number, then *filenumber* is an integer representing the number found in the `FILE#` column of the `V$DATAFILE` dynamic performance view or in the `FILE_ID` column of the `DBA_DATA_FILES` data dictionary view. The `DATAFILE` clauses affect your database files as follows:

ONLINE

Specify `ONLINE` to bring the data file online.

OFFLINE

Specify `OFFLINE` to take the data file offline. If the database is open, then you must perform media recovery on the data file before bringing it back online, because a checkpoint is not performed on the data file before it is taken offline.

FOR DROP

If the database is in `NOARCHIVELOG` mode, then you must specify `FOR DROP` clause to take a data file offline. However, this clause does not remove the data file from the database. To do that, you must use an operating system command or drop the tablespace in which the data file resides. Until you do so, the data file remains in the data dictionary with the status `RECOVER` or `OFFLINE`.

If the database is in `ARCHIVELOG` mode, then Oracle Database ignores the `FOR DROP` clause.

RESIZE

Specify `RESIZE` if you want Oracle Database to attempt to increase or decrease the size of the data file to the specified absolute size in bytes. There is no default, so you must specify a size. You can also use this command to resize datafiles in shadow tablespaces, that store lost write data.

If sufficient disk space is not available for the increased size, or if the file contains data beyond the specified decreased size, then Oracle Database returns an error.

> **See Also:**
>
> "Resizing a Data File: Example"

END BACKUP

Specify `END BACKUP` to take the data file out of online backup mode. The `END BACKUP` clause is described more fully at the top level of the syntax of `ALTER DATABASE`. See "END BACKUP Clause".

ENCRYPT | DECRYPT

Use these clauses to perform offline encryption or decryption of the data file using Transparent Data Encryption (TDE). In any given tablespace, either all data files must be encrypted or all data files must be unencrypted.

Before issuing either of these clauses, the database must be mounted. The database can also be open, but the tablespace that contains the data file being encrypted or decrypted must be offline. The TDE master key must be loaded into database memory.

- Specify `ENCRYPT` to encrypt an unencrypted data file. The data file is encrypted using the `AES128` algorithm.
- Specify `DECRYPT` to decrypt a data file. The data file must have been previously encrypted with the `ALTER DATABASE DATAFILE ... ENCRYPT` statement.

Restrictions on Encrypting and Decrypting Data Files

The following restrictions apply to the `ENCRYPT` and `DECRYPT` clauses:

- You cannot encrypt or decrypt a temporary data file of a temporary tablespace. Instead, you must drop the temporary tablespace and recreate it as an encrypted tablespace.
- Oracle recommends against encrypting the data files of an undo tablespace. Doing so prevents the keystore from being closed, which prevents the database from functioning. Furthermore, this practice is unnecessary because all undo records that are associated with an encrypted tablespace are already automatically encrypted in the undo tablespace.

> **Note:**
>
> The use of the `ENCRYPT` or `DECRYPT` clause is only one step in a series of steps for performing offline encryption or decryption of a data file. Refer to *Transparent Data Encryption* for the complete set of steps before you use either of these clauses.

alter_tempfile_clause

Use the `TEMPFILE` clause to resize your temporary data file or specify the *`autoextend_clause`*, with the same effect as for a permanent data file. The database must be open. You can identify the temp file by name or by number. If you identify it by number, then *`filenumber`* is an integer representing the number found in the `FILE#` column of the `V$TEMPFILE` dynamic performance view.

> **Note:**
>
> On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

DROP

Specify `DROP` to drop *`tempfile`* from the database. The tablespace remains.

If you specify `INCLUDING DATAFILES`, then Oracle Database also deletes the associated operating system files and writes a message to the alert log for each such deleted file. You can achieve the same result using an `ALTER TABLESPACE ... DROP TEMPFILE` statement. Refer to the `ALTER TABLESPACE` DROP Clause for more information.

move_datafile_clause

Use the `MOVE DATAFILE` clause to move an online data file to a new location. The database can be open and accessing the data file when you perform this operation. The database creates a copy of the data file when it is performing this operation. Ensure that there is adequate disk space for the original data file and the copy before using this clause.

You can specify the original data file using the *`file_name`*, *`ASM_filename`*, or *`file_number`*. Refer to *ASM_filename* for information on ASM file names. If you identify the file by number, then *`file_number`* is an integer representing the number found in the `FILE#` column of the `V$DATAFILE` dynamic performance view or in the `FILE_ID` column of the `DBA_DATA_FILES` data dictionary view.

Use the `TO` clause to specify the new *`file_name`* or *`ASM_filename`*. If you are using Oracle Managed Files, then you can omit the `TO` clause. In this case, Oracle Database creates a unique name for the data file and saves it in the directory specified by the `DB_CREATE_FILE_DEST` initialization parameter.

If you specify `REUSE`, then the new data file is created even if it already exists.

If you specify `KEEP`, then the original data file will be kept after the `MOVE DATAFILE` operation. You cannot specify `KEEP` if the original data file is an Oracle Managed File. You can specify `KEEP` if the new data file is an Oracle Managed File.

autoextend_clause

Use the *`autoextend_clause`* to enable or disable the automatic extension of a new or existing data file or temp file. Refer to *file_specification* for information about this clause.

logfile_clauses

The logfile clauses let you add, drop, or modify log files.

ARCHIVELOG

Specify ARCHIVELOG if you want the contents of a redo log file group to be archived before the group can be reused. This mode prepares for the possibility of media recovery. Use this clause only after shutting down your instance normally, or immediately with no errors, and then restarting it and mounting the database.

MANUAL

Specify MANUAL to indicate that Oracle Database should create redo log files, but the archiving of the redo log files is controlled entirely by the user. This clause is provided for backward compatibility, for example for users who archive directly to tape. If you specify MANUAL, then:

- Oracle Database does not archive redo log files when a log switch occurs. You must handle this manually.
- You cannot have specified a standby database as an archivelog destinations. As a result, the database cannot be in MAXIMUM PROTECTION or MAXIMUM AVAILABILITY standby protection mode.

If you omit this clause, then Oracle Database automatically archives the redo log files to the destination specified in the LOG_ARCHIVE_DEST_*n* initialization parameters.

NOARCHIVELOG

Specify NOARCHIVELOG if you do not want the contents of a redo log file group to be archived so that the group can be reused. This mode does not prepare for recovery after media failure. Use this clause only if your instance has the database mounted but not open.

[NO] FORCE LOGGING

Use this clause to put the database into or take the database out of FORCE LOGGING mode. The database must be mounted or open.

In FORCE LOGGING mode, Oracle Database logs all changes in the database except changes in temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any NOLOGGING or FORCE LOGGING settings you specify for individual tablespaces and any NOLOGGING settings you specify for individual database objects.

If you specify FORCE LOGGING, then Oracle Database waits for all ongoing unlogged operations to finish.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information on when to use FORCE LOGGING mode

SET STANDBY NOLOGGING

Standby nologging instructs the database to not log operations that qualify to be done without logging. The database sends the data blocks created by the operation to each qualifying standby database in the Data Guard configuration, to prevent missed data on the standby and keep it in sync with the primary.

Use this clause to determine how nonlogged tasks are handled . You can choose one of two logging modes for a database when you create the database, and you can change the logging mode of a database from one mode to the other.

- SET STANDBY NOLOGGING FOR LOAD PERFORMANCE to put the database into standby nologging for load performance mode. In this mode, the data loaded as part of the

nonlogged task is sent to the qualifying standbys via a private network connection, provided that doing so will not slow down the load process. If the load process slows, then the data is not sent but automatically fetched from the primary as each standby encounters the invalidation redo and will be retried until the data blocks are eventually received.

- Specify `SET STANDBY NOLOGGING FOR DATA AVAILABILITY` to put the database into standby nologging for data availability mode. In this mode the data loaded as part of the nonlogged task is sent to the qualifying standbys either via a network connection or via block images in the redo, in case the network connection fails. That is to say, in this mode the load will switch to be done in a logged fashion if the network connection or related processes prevent the sending of the data over the private network connection.

For the standby nologging modes, a qualifying standby is one that is open for read, running managed recovery and receiving redo into standby redo logs.

Restrictions on Setting Standby Nologging

The`SET STANDBY NOLOGGING` clause cannot be used at the same time as `FORCE LOGGING`.

RENAME FILE Clause

This clause has the same function for logfiles that it has for data files and temp files. See "RENAME FILE Clause".

CLEAR LOGFILE Clause

Use the `CLEAR LOGFILE` clause to reinitialize an online redo log, optionally without archiving the redo log. `CLEAR LOGFILE` is similar to adding and dropping a redo log, except that the statement may be issued even if there are only two logs for the thread and may be issued for the current redo log of a closed thread.

For a standby database, if the `STANDBY_FILE_MANAGEMENT` initialization parameter is set to `AUTO`, and if any of the log files are Oracle Managed Files, Oracle Database will create as many Oracle-managed log files as are in the control file. The log file members will reside in the current default log file destination.

- You must specify `UNARCHIVED` if you want to reuse a redo log that was not archived.

> **Note:**
>
> Specifying `UNARCHIVED` makes backups unusable if the redo log is needed for recovery.

- You must specify `UNRECOVERABLE DATAFILE` if you have taken the data file offline with the database in `ARCHIVELOG` mode (that is, you specified `ALTER DATABASE ... DATAFILE OFFLINE` without the `DROP` keyword), and if the unarchived log to be cleared is needed to recover the data file before bringing it back online. In this case, you must drop the data file and the entire tablespace once the `CLEAR LOGFILE` statement completes.

  Do not use `CLEAR LOGFILE` to clear a log needed for media recovery. If it is necessary to clear a log containing redo after the database checkpoint, then you must first perform incomplete media recovery. The current redo log of an open thread can be cleared. The current log of a closed thread can be cleared by switching logs in the closed thread.

  If the `CLEAR LOGFILE` statement is interrupted by a system or instance failure, then the database may hang. In this case, reissue the statement after the database is restarted. If the failure occurred because of I/O errors accessing one member of a log group, then that member can be dropped and other members added.

> **See Also:**
>
> "Clearing a Log File: Example"

add_logfile_clauses

Use these clauses to add redo log file groups to the database and to add new members to existing redo log file groups.

ADD LOGFILE Clause

Use the `ADD LOGFILE` clause to add one or more redo log file groups to the online redo log or standby redo log.

> **See Also:**
>
> - "LOGFILE Clause" of `CREATE DATABASE` for information on the result of this clause for Oracle Managed Files if you do not specify a name for the new log file group
> - "Adding Redo Log File Groups: Examples"
> - *Oracle Data Guard Concepts and Administration* for more information on standby redo logs

STANDBY

Use the `STANDBY` clause to add a redo log file group to the standby redo log. If you do not specify this clause, then a log file group is added to the online redo log.

INSTANCE

The `INSTANCE` clause is applicable only for Oracle Real Application Clusters (Oracle RAC) or Oracle RAC One Node databases. Specify the name of the instance for which you want to add a redo log file group. The instance name is a string of up to 80 characters. Oracle Database automatically uses the thread that is mapped to the specified instance. If no thread is mapped to the specified instance, then Oracle Database automatically acquires an available unmapped thread and assigns it to that instance. If you do not specify this clause, then Oracle Database executes the command as if you had specified the current instance. If the specified instance has no current thread mapping and there are no available unmapped threads, then Oracle Database returns an error.

THREAD

When adding a redo log file group to the standby redo log, use the `THREAD` clause to assign the log file group to a specific primary database redo thread. Query the `V$INSTANCE` view on the primary database to determine which redo threads have been opened, and specify one of these thread numbers.

You can also use the `THREAD` clause to assign a log file group to a specific redo thread when adding the log file group to the online redo log. This usage has been deprecated. The `INSTANCE` clause achieves the same purpose and is easier to use.

GROUP

The GROUP clause uniquely identifies the redo log file group among all groups in all threads and can range from 1 to the value specified for MAXLOGFILES in the CREATE DATABASE statement. You cannot add multiple redo log file groups having the same GROUP value. If you omit this parameter, then Oracle Database generates its value automatically. You can examine the GROUP value for a redo log file group through the dynamic performance view V$LOG.

redo_log_file_spec

Each *redo_log_file_spec* specifies a redo log file group containing one or more members (copies). If you do not specify a filename for the new log file, then Oracle Database creates Oracle Managed Files according to the rules described in the "LOGFILE Clause" of CREATE DATABASE.

> **See Also:**
>
> - *file_specification*
> - *Oracle Database Reference* for information on dynamic performance views

ADD LOGFILE MEMBER Clause

Use the ADD LOGFILE MEMBER clause to add new members to existing redo log file groups. Each new member is specified by *'filename'*. If the file already exists, then it must be the same size as the other group members and you must specify REUSE. If the file does not exist, then Oracle Database creates a file of the correct size. You cannot add a member to a group if all of the members of the group have been lost through media failure.

STANDBY

You must specify STANDBY when adding a member to a standby redo log file group. Otherwise, Oracle Database returns an error.

You can use the *logfile_descriptor* clause to specify an existing redo log file group in one of two ways:

GROUP *integer*

Specify the value of the GROUP parameter that identifies the redo log file group.

***filename*(s)**

List all members of the redo log file group. You must fully specify each filename according to the conventions of your operating system.

> **See Also:**
>
> - "LOGFILE Clause" of CREATE DATABASE for information on the result of this clause for Oracle Managed Files if you do not specify a name for the new log file group
> - "Adding Redo Log File Group Members: Example"

drop_logfile_clauses

Use these clauses to drop redo log file groups or redo log file members.

DROP LOGFILE Clause

Use the `DROP LOGFILE` clause to drop all members of a redo log file group. If you use this clause to drop Oracle Managed Files, then Oracle Database also removes all log file members from disk. Specify a redo log file group as indicated for the `ADD LOGFILE MEMBER` clause.

- To drop the current log file group, you must first issue an `ALTER SYSTEM SWITCH LOGFILE` statement.
- You cannot drop a redo log file group if it needs archiving.
- You cannot drop a redo log file group if doing so would cause the redo thread to contain less than two redo log file groups.

> **See Also:**
>
> ALTER SYSTEM and "Dropping Log File Members: Example"

DROP LOGFILE MEMBER Clause

Use the `DROP LOGFILE MEMBER` clause to drop one or more redo log file members. Each *'filename'* must fully specify a member using the conventions for filenames on your operating system.

- To drop a log file in the current log, you must first issue an `ALTER SYSTEM SWITCH LOGFILE` statement. Refer to ALTER SYSTEM for more information.
- You cannot use this clause to drop all members of a redo log file group that contains valid data. To perform that operation, use the `DROP LOGFILE` clause.

> **See Also:**
>
> "Dropping Log File Members: Example"

switch_logfile_clause

This clause is useful when you are migrating the database to disks with a different block size that the block size of the current database. Use this clause to switch logfiles to a different block size for all externally enabled threads, including both open and closed threads. If you are migrating the database to use 4KB sector disks, then you must specify 4096 for *integer*. If you are unmigrating the database back to using 512B sector disks, then you must specify 512 for *integer*.

This clause is an extension of the existing `ALTER SYSTEM SWITCH LOGFILE` statement. That statement switches logs for a single thread. This clause switches logfiles for all externally enabled threads, including both open and closed threads.

Before using this clause, you must already have created at least two redo log groups with the same target block size on the migration target disk.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information on migrating the database to disks with a different block size, and "Adding a Log File: Example"

supplemental_db_logging

Use these clauses to instruct Oracle Database to add or stop adding supplemental data into the log stream.

ADD SUPPLEMENTAL LOG Clause

Specify `ADD SUPPLEMENTAL LOG DATA` to enable **minimal supplemental logging**. Specify `ADD SUPPLEMENTAL LOG` *`supplemental_id_key_clause`* to enable column data logging in addition to minimal supplemental logging. Specify `ADD SUPPLEMENTAL LOG` *`supplemental_plsql_clause`* to enable supplemental logging of PL/SQL calls. Oracle Database does not enable either minimal supplemental logging or supplemental logging by default.

Minimal supplemental logging ensures that LogMiner (and any products building on LogMiner technology) will have sufficient information to support chained rows and various storage arrangements such as cluster tables.

If the redo generated on one database is to be the source of changes (to be mined and applied) at another database, as is the case with logical standby, then the affected rows need to be identified using column data (as opposed to rowids). In this case, you should specify the *`supplemental_id_key_clause`*.

You can query the appropriate columns in the `V$DATABASE` view to determine whether any supplemental logging has already been enabled.

You can use this clause when the database is open. However, Oracle Database will invalidate all DML cursors in the cursor cache, which will have an effect on performance until the cache is repopulated.

If you use this clause in a CDB, then the current container must be the root and the operation will be performed on the entire CDB.

You can enable supplemental logging levels at PDB without minimal supplemental logging enabled at `CDB$ROOT`. Dropping all supplemental logging from `CDB$ROOT` will not disable supplemental logging enabled at the PDB level.

For a full discussion of the *`supplemental_id_clause`*, refer to supplemental_id_key_clause in the documentation on `CREATE TABLE`.

> **See Also:**
>
> - *Oracle Data Guard Concepts and Administration* for information on supplemental logging on the primary database to support a logical standby database
> - *Oracle Database Utilities* for examples using the *`supplemental_db_logging`* clause syntax

DROP SUPPLEMENTAL LOG Clause

Use this clause to stop supplemental logging.

- Specify `DROP SUPPLEMENTAL LOG DATA` to instruct Oracle Database to stop placing minimal additional log information into the redo log stream whenever an update operation occurs. If Oracle Database is doing column data supplemental logging specified with the *`supplemental_id_key_clause`*, then you must first stop the column data supplemental logging with the `DROP SUPPLEMENTAL LOG` *`supplemental_id_key_clause`* and then specify this clause.
- Specify `DROP SUPPLEMENTAL LOG` *`supplemental_id_key_clause`* to drop some or all of the system-generated supplemental log groups. You must specify the *`supplemental_id_key_clause`* if the supplemental log groups you want to drop were added using that clause.
- Specify `DROP SUPPLEMENTAL LOG` *`supplemental_plsql_clause`* disable supplemental logging of PL/SQL calls.

If you use this clause in a CDB, then the current container must be the root and the operation will be performed on the entire CDB.

ADD SUPPLEMENTAL LOG DATA SUBSET DATABASE REPLICATION of `ALTER DATABASE` enables low impact minimal supplemental logging.

- You can execute this DDL only when the *`enable_goldengate_replication`* parameter is TRUE, and database compatible is 19.0 or higher.
- This DDL implicitly adds DB-level minimal supplemental logging, similar to other DB-level supplemental logging DDLs.
- In case of CDB, this DDL can be executed in both `CDB$ROOT` and pluggable databases.
- When executed in `CDB$ROOT`, it enables low impact minimal supplemental logging for entire database. Low impact minimal supplemental logging will be enabled for all the pluggable databases regardless of the PDB level setting for subset database replication.
- When executed in pluggable database, it's same as `ALTER PLUGGABLE DATABASE ADD SUPPLEMENTAL LOG DATA SUBSET DATABASE REPLICATION`. See *ALTER PLUGGABLE DATABASE* for details.

DROP SUPPLEMENTAL LOG DATA SUBSET DATABASE REPLICATION of `ALTER DATABASE` disables low impact minimal supplemental logging.

- You can execute this DDL only when the*`enable_goldengate_replication`* parameter is TRUE, and database compatible should be 19.0 or higher.
- You must have explicitly enabled other supplemental log data. This restriction ensures that disabling low impact minimal supplemental logging never disables minimal supplemental logging.
- Once this DDL is executed, the minimal supplemental logging will go back to its current behavior.
- In case of CDB, this DDL can be executed in both `CDB$ROOT` and pluggable databases.
- When executed in `CDB$ROOT` , it disables low impact minimal supplemental logging at the database level. For each pluggable database, whether low impact supplemental logging is enabled depends on the PDB-level setting for subset database replication.
- When executed in pluggable database, the behavior is the same as `ALTER PLUGGABLE DATABASE DROP SUPPLEMENTAL LOG DATA SUBSET DATABASE REPLICATION`. See *ALTER PLUGGABLE DATABASE* for details.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for information on supplemental logging

controlfile_clauses

The *controlfile_clauses* let you create or back up a control file.

CREATE CONTROLFILE Clause

The CREATE CONTROLFILE clause lets you create a control file.

- Specify PHYSICAL STANDBY to create a control file to be used to maintain a physical database. This is the default if you specify STANDBY and do not specify PHYSICAL or LOGICAL.
- Specify LOGICAL STANDBY to create a control file to be used to maintain a logical database.
- Specify FAR SYNC INSTANCE to create a control file to be used to maintain a Data Guard far sync instance.

If the file already exists, then you must specify REUSE. In an Oracle RAC environment, the control file must be on shared storage.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information on creating control files

BACKUP CONTROLFILE Clause

Use the BACKUP CONTROLFILE clause to back up the current control file. The database must be open or mounted when you specify this clause.

TO '*filename*'

Use this clause to specify a binary backup of the control file. You must fully specify the *filename* using the conventions for your operating system. If the specified file already exists, then you must specify REUSE. In an Oracle RAC environment, *filename* must be on shared storage.

A binary backup contains information that is not captured if you specify TO TRACE, such as the archived log history, offline range for read-only and offline tablespaces, and backup sets and copies (if you use RMAN). If the COMPATIBLE initialization parameter is 10.2 or higher, binary control file backups include temp file entries.

TO TRACE

Specify TO TRACE if you want Oracle Database to write SQL statements to a trace file rather than making a physical backup of the control file. You can use SQL statements written to the trace file to start up the database, re-create the control file, and recover and open the database appropriately, based on the created control file. If you issue an ALTER DATABASE BACKUP CONTROLFILE TO TRACE statement while block change tracking is enabled, then the resulting trace file will contain a command to reenable block change tracking.

This statement issues an implicit `ALTER DATABASE REGISTER LOGFILE` statement, which creates incarnation records if the archived log files reside in the current archivelog destinations.

The trace file will also include `ALTER DATABASE REGISTER LOGFILE` statements for existing logfiles that reside in the current archivelog destinations. This will implicitly create database incarnation records for the branches of redo to which the logfiles apply.

You can copy the statements from the trace file into a script file, edit the statements as necessary, and use the script if all copies of the control file are lost (or to change the size of the control file).

- Specify `AS` *`filename`* if you want Oracle Database to place the trace output into a file called *`filename`* rather than into the standard trace file.
- Specify `REUSE` to allow Oracle Database to overwrite any existing file called *`filename`*.
- `RESETLOGS` indicates that the SQL statement written to the trace file for starting the database is `ALTER DATABASE OPEN RESETLOGS`. This setting is valid only if the online logs are unavailable.
- `NORESETLOGS` indicates that the SQL statement written to the trace file for starting the database is `ALTER DATABASE OPEN NORESETLOGS`. This setting is valid only if all the online logs are available.

If you cannot predict the future state of the online logs, then specify neither `RESETLOGS` nor `NORESETLOGS`. In this case, Oracle Database puts both versions of the script into the trace file, and you can choose which version is appropriate when the script becomes necessary.

The trace files are stored in a subdirectory determined by the `DIAGNOSTIC_DEST` initialization parameter. You can find the name and location of the trace file to which the `CREATE CONTROLFILE` statements were written by looking in the alert log. You can also find the directory for trace files by querying the `NAME` and `VALUE` columns of the `V$DIAG_INFO` dynamic performance view.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information on viewing the alert log

standby_database_clauses

Use these clauses to activate the standby database or to specify whether it is in protected or unprotected mode.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for descriptions of the physical and logical standby database and for information on maintaining and using standby databases

activate_standby_db_clause

Use the `ACTIVATE STANDBY DATABASE` clause to convert a standby database into a primary database.

> **Note:**
>
> Before using this command, refer to *Oracle Data Guard Concepts and Administration* for important usage information.

PHYSICAL

Specify `PHYSICAL` to activate a physical standby database. This is the default.

LOGICAL

Specify `LOGICAL` to activate a logical standby database. If you have more than one logical standby database, then you should first ensure that the same log data is available on all the standby systems.

FINISH APPLY

This clause applies only to logical standby databases. Use it to initiate **terminal apply**, which is the application of any remaining redo to bring the logical standby database to the same state as the primary database. When terminal apply is complete, the database completes the switchover from logical standby to primary database.

If you require immediate restoration of the database in spite of data loss, then omit this clause. The database will execute the switchover from logical standby to primary database immediately without terminal apply.

maximize_standby_db_clause

Use this clause to specify the level of protection for the data in your database environment. You specify this clause from the primary database.

> **Note:**
>
> The `PROTECTED` and `UNPROTECTED` keywords have been replaced for clarity but are still supported. `PROTECTED` is equivalent to `TO MAXIMIZE PROTECTION`. `UNPROTECTED` is equivalent to `TO MAXIMIZE PERFORMANCE`.

TO MAXIMIZE PROTECTION

This setting establishes **maximum protection mode** and offers the highest level of data protection. A transaction does not commit until all data needed to recover that transaction has been written to at least one physical standby database that is configured to use the `SYNC` log transport mode. If the primary database is unable to write the redo records to at least one such standby database, then the primary database is shut down. This mode guarantees zero data loss, but it has the greatest potential impact on the performance and availability of the primary database.

Restriction on Establishing Maximum Protection Mode

You can specify `TO MAXIMIZE PROTECTION` on an open database only if the current data protection mode is `MAXIMUM AVAILABILITY` and there is at least one synchronized standby database.

TO MAXIMIZE AVAILABILITY

This setting establishes **maximum availability mode** and offers the next highest level of data protection. A transaction does not commit until all data needed to recover that transaction has been written to at least one physical or logical standby database that is configured to use the SYNC log transport mode. Unlike maximum protection mode, the primary database does not shut down if it is unable to write the redo records to at least one such standby database. Instead, the protection is lowered to maximum performance mode until the fault has been corrected and the standby database has caught up with the primary database. This mode guarantees zero data loss unless the primary database fails while in maximum performance mode. Maximum availability mode provides the highest level of data protection that is possible without affecting the availability of the primary database.

TO MAXIMIZE PERFORMANCE

This setting establishes **maximum performance mode** and is the default setting. A transaction commits before the data needed to recover that transaction has been written to a standby database. Therefore, some transactions may be lost if the primary database fails and you are unable to recover the redo records from the primary database. This mode provides the highest level of data protection that is possible without affecting the performance of the primary database.

To determine the current mode of the database, query the PROTECTION_MODE column of the V$DATABASE dynamic performance view.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for full information on using these standby database settings

register_logfile_clause

Specify the REGISTER LOGFILE clause from the standby database to manually register log files from the failed primary. Use the *redo_log_file_spec* form of *file_specification* (see *file_specification*) to list regular redo log files in an operating system file system or to list Oracle ASM disk group redo log files.

When a log file is from an unknown incarnation, the REGISTER LOGFILE clause causes an incarnation record to be added to the V$DATABASE_INCARNATION view. If the newly registered log file belongs to an incarnation having a higher RESETLOGS_TIME than the current RECOVERY_TARGET_INCARNATION#, then the REGISTER LOGFILE clause also causes RECOVERY_TARGET_INCARNATION# to be changed to correspond to the newly added incarnation record.

OR REPLACE

Specify OR REPLACE to allow an existing archivelog entry in the standby database to be updated, for example, when its location or file specification changes. The system change numbers of the entries must match exactly, and the original entry must have been created by the managed standby log transmittal mechanism.

FOR *logminer_session_name*

This clause is useful in a Streams environment. It lets you register the log file with one specified LogMiner session.

switchover_clause

> **Caution:**
>
> Before using this command, refer to *Oracle Data Guard Concepts and Administration* for complete usage information.

Use this clause to perform a switchover to a physical standby database. Specify this clause from the primary database. For *target_db_name*, specify the DB_UNIQUE_NAME of the standby database.

VERIFY

Use this clause to verify that a physical standby database is ready for a switchover. Specify this clause from the primary database. For *target_db_name*, specify the DB_UNIQUE_NAME of the standby database. If the standby database is ready for a switchover, then the "Database Altered" message is returned. Otherwise, an error message that will assist you in preparing the standby database for a switchover is returned.

FORCE

Use this clause if a previous switchover command failed and created a configuration with no primary database. Specify this clause from the physical standby database that you want to convert to the primary database. For *target_db_name*, specify the DB_UNIQUE_NAME of the database that you want to convert to the primary database.

failover_clause

> **Caution:**
>
> Before using this command, refer to *Oracle Data Guard Concepts and Administration* for complete usage information.

Use this clause to perform a failover to a physical standby database. Specify this clause from the standby database. For *target_db_name*, specify the DB_UNIQUE_NAME of the standby database.

FORCE

This clause has meaning only when the failover target is serviced by a Data Guard far sync instance. Use this clause when a previous failover command failed and the reason for the failure cannot be resolved. It instructs the failover to ignore any failures encountered when interacting with the Data Guard far sync instance and proceed with the failover, if at all possible.

commit_switchover_clause

Use this clause to perform database role transitions in a Data Guard configuration.

> **Caution:**
>
> Before using this command, refer to *Oracle Data Guard Concepts and Administration* for complete usage information.

PREPARE TO SWITCHOVER

This clause prepares a primary database to become a logical standby database or a logical standby database to become a primary database.

- Specify `PREPARE TO SWITCHOVER TO LOGICAL STANDBY` on a primary database.
- Specify `PREPARE TO SWITCHOVER TO PRIMARY DATABASE` on a logical standby database.

COMMIT TO SWITCHOVER

This clause switches a primary database to a standby database role or switches a standby database to the primary database role.

- Specify `COMMIT TO SWITCHOVER TO PHYSICAL STANDBY` or `COMMIT TO SWITCHOVER TO LOGICAL STANDBY` on a primary database.
- Specify `COMMIT TO SWITCHOVER TO PRIMARY DATABASE` on a standby database.

PHYSICAL

This clause is always optional. Use of this clause with the `COMMIT TO SWITCHOVER TO PRIMARY` clause has been deprecated.

LOGICAL

This clause is specified with the `PREPARE TO SWITCHOVER` or `COMMIT TO SWITCHOVER` clauses when switching a primary database to the logical standby database role. Use of this clause with the `COMMIT TO SWITCHOVER TO PRIMARY` clause has been deprecated.

WITH SESSION SHUTDOWN

This clause causes all database sessions to be closed and uncommitted transactions to be rolled back before performing a database role transition.

WITHOUT SESSION SHUTDOWN

This clause prevents a requested role transition from occurring if there are any database sessions. This is the default.

WAIT

Specify this clause to wait for a role transition to complete before returning control to the user.

NOWAIT

Specify this clause to return control to the user without waiting for a role transition to complete. This is the default.

CANCEL

Specify this clause to reverse the effect of a previously specified `PREPARE TO SWITCHOVER` statement.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for full information on switchover between primary and standby databases

start_standby_clause

Specify the `START LOGICAL STANDBY APPLY` clause to begin applying redo logs to a logical standby database. This clause enables primary key, unique index, and unique constraint supplemental logging as well as PL/SQL call logging.

- Specify `IMMEDIATE` to apply redo data from the current standby redo log file.
- Specify `NODELAY` if you want Oracle Database to ignore a delay for this apply. This is useful if the primary database is no longer present, which would otherwise require a PL/SQL call to be made.
- Specify `INITIAL` the first time you apply the logs to the standby database.
- The `NEW PRIMARY` clause is needed in two situations:
  - On a failover to a logical standby, specify this clause on a logical standby not participating in the failover operation, and on the old primary database after it has been reinstated as a logical standby database.
  - During a rolling upgrade using a logical standby database (which uses an unprepared switchover operation), specify this clause after the original primary database has been upgraded to the new database software.
- Specify `SKIP FAILED` [`TRANSACTION`] to skip the last transaction in the events table and restart the apply.
- Specify `FINISH` to force the standby redo logfile information into archived logs. If the primary database becomes disabled, then you can then apply the data in the redo log files.

stop_standby_clause

Use this clause to stop the log apply services. This clause applies only to logical standby databases, not to physical standby databases. Use the `STOP` clause to stop the apply in an orderly fashion.

convert_database_clause

Use this clause to convert a database from one form to another.

- Specify `CONVERT TO PHYSICAL STANDBY` to convert a primary database, a logical standby database, or a snapshot standby database into a physical standby database.

  Perform these steps before specifying this clause:
  - On an Oracle Real Application Clusters (Oracle RAC) database, shut down all but one instance.
  - Ensure that the database is mounted, but not open.

  The database is dismounted after conversion and must be restarted.
- Specify `CONVERT TO SNAPSHOT STANDBY` to convert a physical standby database into a snapshot standby database.

  Ensure that redo apply is stopped before specifying this clause.

> **Note:**
>
> A snapshot standby database must be opened at least once in read/write mode before it can be converted into a physical standby database.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information about standby databases

default_settings_clauses

Use these clauses to modify the default settings of the database.

DEFAULT EDITION Clause

Use this clause to designate the specified edition as the default edition for the database. The specified edition must already have been created and must be `USABLE`. The change takes place immediately and is visible to all nodes in an Oracle RAC environment. New database sessions automatically start out in the specified edition. The new setting persists across database shutdown and startup.

When you designate an edition as the database default edition, all users can use the edition, as though the `USE` object privilege were granted on the specified edition to the role `PUBLIC`.

You can determine the current default edition of the database with the following query:

```
SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES
  WHERE PROPERTY_NAME = 'DEFAULT_EDITION';
```

> **See Also:**
>
> CREATE EDITION for more information on editions and *Oracle Database PL/SQL Language Reference* for information on how editions are designated as `USABLE`

CHARACTER SET, NATIONAL CHARACTER SET

You can no longer change the database character set or the national character set using the `ALTER DATABASE` statement. Refer to *Oracle Database Globalization Support Guide* for information on database character set migration.

SET DEFAULT TABLESPACE Clause

Use this clause to specify or change the default type of subsequently created tablespaces. Specify `BIGFILE` or `SMALLFILE` to indicate whether the tablespaces should be bigfile or smallfile tablespaces.

- A **bigfile tablespace** contains only one data file or temp file, which can contain up to approximately 4 billion (2^{32}) blocks. The maximum size of the single data file or temp file is 128 terabytes (TB) for a tablespace with 32K blocks and 32TB for a tablespace with 8K blocks.

- A **smallfile tablespace** is a traditional Oracle tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million (2^{22}) blocks.

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for more information about bigfile tablespaces
> - "Setting the Default Type of Tablespaces: Example"

DEFAULT TABLESPACE Clause

Specify this clause to establish or change the default permanent tablespace of the database. The tablespace you specify must already have been created. After this operation completes, Oracle Database automatically reassigns to the new default tablespace all non-`SYSTEM` users. All objects subsequently created by those users will by default be stored in the new default tablespace. If you are replacing a previously specified default tablespace, then you can move the previously created objects from the old to the new default tablespace, and then drop the old default tablespace if you want to.

DEFAULT [LOCAL] TEMPORARY TABLESPACE Clause

Specify this clause to change the default shared temporary tablespace of the database to a new tablespace or tablespace group, or to change the default local temporary tablespace to a new tablespace.

- Specify *`tablespace`* to indicate the new default temporary tablespace for the database. After this operation completes, Oracle Database automatically reassigns to the new default temporary tablespace all users who had been assigned to the old default temporary tablespace. You can then drop the old default temporary tablespace if you want to. Specify `DEFAULT TEMPORARY TABLESPACE` to change the default shared temporary tablespace. Specify `DEFAULT LOCAL TEMPORARY TABLESPACE` to change the default local temporary tablespace.
- Specify *`tablespace_group_name`* to indicate that all tablespaces in the tablespace group specified by *`tablespace_group_name`* are now default shared temporary tablespaces for the database. After this operation completes, users who have not been explicitly assigned a default temporary tablespace can create temporary segments in any of the tablespaces that are part of *`tablespace_group_name`*. You cannot drop an old default temporary tablespace if it is part of the default temporary tablespace group. Local temporary tablespaces cannot be part of a tablespace group.

To learn the name of the current default temporary tablespace or default temporary tablespace group, query the `TEMPORARY_TABLESPACE` column of the `ALL_`, `DBA_`, or `USER_USERS` data dictionary views.

Restrictions on Default Temporary Tablespaces

Default temporary tablespaces are subject to the following restrictions:

- The tablespace you assign or reassign as the default temporary tablespace must have a standard block size.
- If the `SYSTEM` tablespace is locally managed, then the tablespace you specify as the default temporary tablespace must also be locally managed.

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for information on tablespace groups
> - "Changing the Default Temporary Tablespace: Examples"

instance_clauses

In an Oracle Real Application Clusters environment, specify `ENABLE INSTANCE` to enable the thread that is mapped to the specified database instance. The thread must have at least two redo log file groups, and the database must be open.

Specify `DISABLE INSTANCE` to disable the thread that is mapped to the specified database instance. The name of the instance is a string of up to 80 characters. If no thread is currently mapped to the specified instance, then Oracle Database returns an error. The database must be open, but you cannot disable a thread if an instance using it has the database mounted.

> **See Also:**
>
> *Oracle Real Application Clusters Administration and Deployment Guide* for more information on enabling and disabling instances

RENAME GLOBAL_NAME Clause

Specify `RENAME GLOBAL_NAME` to change the global name of the database. The database must be open. The *`database`* is the new database name and can be as long as eight bytes. The optional *`domain`* specifies where the database is effectively located in the network hierarchy. If you specify a domain name, then the components of the domain name must be legal identifiers. See "Database Object Naming Rules " for information on valid identifiers.

> **Note:**
>
> Renaming your database does not change global references to your database from existing database links, synonyms, and stored procedures and functions on remote databases. Changing such references is the responsibility of the administrator of the remote databases.

> **See Also:**
>
> "Changing the Global Database Name: Example"

BLOCK CHANGE TRACKING Clauses

The **block change tracking** feature causes Oracle Database to keep track of the physical locations of all database updates on both the primary database and any physical standby database. You must enable block change tracking on each database for which you want tracking to be performed. The tracking information is maintained in a separate file called the

block change tracking file. If you are using Oracle Managed Files, then Oracle Database automatically creates the block change tracking file in the location specified by `DB_CREATE_FILE_DEST`. If you are not using Oracle Managed Files, then you must specify the change tracking filename. Oracle Database uses change tracking data for some internal tasks, such as increasing the performance of incremental backups. You can enable or disable block change tracking with the database either open or mounted, in either archivelog or `NOARCHIVELOG` mode.

ENABLE BLOCK CHANGE TRACKING

This clause enables block change tracking and causes Oracle Database to create a block change tracking file.

- Specify `USING FILE '`*`filename`*`'` if you want to name the block change tracking file instead of letting Oracle Database generate a name for it. You must specify this clause if you are not using Oracle Managed Files.
- Specify `REUSE` to allow Oracle Database to overwrite an existing block change tracking file of the same name.

> **Note:**
>
> On a standby database, the block change tracking only becomes effective when the managed recovery starts. If the recovery is already active on the standby database when you issue the command, the recovery must be stopped and then started again to benefit from the fast incremental backups.

DISABLE BLOCK CHANGE TRACKING

Specify this clause if you want Oracle Database to stop tracking changes and delete the existing block change tracking file.

> **See Also:**
>
> *Oracle Database Backup and Recovery User's Guide* for information on setting up block change tracking and "Enabling and Disabling Block Change Tracking: Examples"

[NO] FORCE FULL DATABASE CACHING

Use this clause to enable or disable the force full database caching mode. In contrast to the default mode, which is automatic, the force full database caching mode considers the entire database, including `NOCACHE` LOBs, as eligible for caching in the buffer cache.

The database must be mounted but not open. In an Oracle RAC environment, the database must be mounted but not open in the current instance and unmounted in all other instances.

- Specify `FORCE FULL DATABASE CACHING` to enable the force full database caching mode.
- Specify `NO FORCE FULL DATABASE CACHING` to disable the force full database caching mode. This is the default mode.

You can determine whether the force full database caching mode is enabled by querying the `FORCE_FULL_DB_CACHING` column of the `V$DATABASE` dynamic performance view.

> **See Also:**
>
> - *Oracle Database Concepts* for more information on the force full database caching mode
> - *Oracle Database Administrator's Guide* to learn how to enable the force full database caching mode
> - *Oracle Database Reference* for more information on the `V$DATABASE` dynamic performance view

CONTAINERS DEFAULT TARGET

Use this clause to specify the default container for DML statements in a CDB. You must be connect to the CDB root.

- For *`container_name`*, specify the name of the default container. The default container can be any container in the CDB, including the CDB root, a PDB, an application root, or an application PDB. You can specify only one default container.
- If you specify `NONE`, then the default container is the CDB root. This is the default.

When a DML statement is issued in a CDB root without specifying containers in the `WHERE` clause, the DML statement affects the default container for the CDB.

flashback_mode_clause

Use this clause to put the database in or take the database out of `FLASHBACK` mode. You can specify this clause only if the database is in `ARCHIVELOG` mode and you have already prepared a fast recovery area for the database. You can specify this clause when the database is mounted or open. This clause cannot be specified on a physical standby database if redo apply is active.

> **See Also:**
>
> *Oracle Database Backup and Recovery User's Guide* for information on preparing the fast recovery area for Flashback operations

FLASHBACK ON

Use this clause to put the database in `FLASHBACK` mode. When the database is in `FLASHBACK` mode, Oracle Database automatically creates and manages Flashback Database logs in the fast recovery area. Users with `SYSDBA` system privilege can then issue a `FLASHBACK DATABASE` statement.

FLASHBACK OFF

Use this clause to take the database out of `FLASHBACK` mode. Oracle Database stops logging Flashback data and deletes all existing Flashback Database logs. Any attempt to issue a `FLASHBACK DATABASE` will fail with an error.

undo_mode_clause

This clause is valid only when you are connected to a CDB. It lets you change the undo mode for the CDB. The CDB must be in `OPEN UPGRADE` mode.

- Specify `LOCAL UNDO ON` to change the CDB to use local undo mode.
- Specify `LOCAL UNDO OFF` to change the CDB to use shared undo mode.

> **See Also:**
>
> - `CREATE DATABASE` *undo_mode_clause* for the full semantics of this clause
> - *Oracle Database Administrator's Guide* for the complete steps for configuring a CDB to use local undo mode or shared undo mode

set_time_zone_clause

This clause has the same semantics in `CREATE DATABASE` and `ALTER DATABASE` statements. When used in with `ALTER DATABASE`, this clause resets the time zone of the database. To determine the time zone of the database, query the built-in function DBTIMEZONE . After setting or changing the time zone with this clause, you must restart the database for the new time zone to take effect.

Oracle Database normalizes all new `TIMESTAMP WITH LOCAL TIME ZONE` data to the time zone of the database when the data is stored on disk.Oracle Database does not automatically update existing data in the database to the new time zone. Therefore, you cannot reset the database time zone if there is any `TIMESTAMP WITH LOCAL TIME ZONE` data in the database. You must first delete or export the `TIMESTAMP WITH LOCAL TIME ZONE` data and then reset the database time zone. For this reason, Oracle does not encourage you to change the time zone of a database that contains data.

For a full description of this clause, refer to *set_time_zone_clause* in the documentation on `CREATE DATABASE`.

security_clause

Use the *`security_clause`* (`GUARD`) to protect data in the database from being changed. You can override this setting for a current session using the `ALTER SESSION DISABLE GUARD` statement. Refer to ALTER SESSION for more information.

ALL

Specify `ALL` to prevent all users other than `SYS` from making any changes to the database.

STANDBY

Specify `STANDBY` to prevent all users other than `SYS` from making changes to any database object being maintained by logical standby. This setting is useful if you want report operations to be able to modify data as long as it is not being replicated by logical standby.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for information on logical standby

NONE

Specify `NONE` if you want normal security for all data in the database.

> **Note:**
>
> Oracle strongly recommends that you not use this setting on a logical standby database.

prepare_clause

- Use this clause to prepare mirror copies of the database. You must provide a *`mirror_name`* to identify the filegroup that is created. The filegroup contains all the prepared files.
- Specify the number of copies to be prepared by the `REDUNDANCY` options: `EXTERNAL`, `NORMAL`, or `HIGH`.
- If you do not specify the redundancy of the mirror, the redundancy of the source database is used.

Prepare a Database : Example

```
ALTER DATABASE db_name PREPARE MIRROR COPY mirror_name WITH HIGH REDUNDANCY
```

drop_mirror_copy

Use this clause to discard mirror copies of data created by the prepare statement. You must specify the same mirror name that you used for the prepare operation.

You cannot use this clause to drop a database that has already been split by the `CREATE DATABASE` or `CREATE PLUGGABLE DATABASE` statement.

lost_write_protection

Specify this clause to enable lost write protection for data files. You can enable, remove, and suspend lost write protection for data files.

Example: Turn on Lost Write for a Datafile

The example turns on lost write on datafile `td_file.df`.

```
ALTER DATABASE DATAFILE td_file.df ENABLE LOST WRITE PROTECTION
```

Note that the lost write database is zeroed out. It is not initialized with the contents of the current data file.

You can turn off lost write protection for a datafile in two ways, with the `REMOVE` or `SUSPEND` options.

1. The `REMOVE` option stops lost write protection for the data file. Additionally, it removes all references to lost write protection including tracking data from the shadow tablespace.

Example: Remove Lost Write for a Datafile

```
ALTER DATABASE DATAFILE td_file.df REMOVE LOST WRITE PROTECTION
```

2. The `SUSPEND` option disables updates and lost write checking, but leaves the tracking data in the shadow tablespace. If you suspend lost write protection for a short time, lost write protection for the data file is stopped during the suspended period. This means that no lost write data is gathered, and no blocks are checked. If you turn on lost write protection for the data file later, there will be no records of SCN updates made to the blocks in the datafile during the suspended period. Note that the `SUSPEND` option does not deallocate the lost write storage.

   Example: Suspend Lost Write for a Datafile

   ```
   ALTER DATABASE DATAFILE td_file.df SUSPEND LOST WRITE PROTECTION
   ```

You can enable lost write protection for container databases and pluggable databases.

Example: Turn on Lost Write for a Database

```
ALTER DATABASE ENABLE LOST WRITE PROTECTION
```

Example: Turn off Lost Write for a Database

```
ALTER DATABASE DISABLE LOST WRITE PROTECTION
```

Note that disabling lost write for the database does not deallocate the lost write storage. You must use the `DROP TABLESPACE` statement to deallocate lost write storage.

cdb_fleet_clauses

Specify the *cdb_fleet_clauses* to set a Lead CDB in a collection of different CDBs.

lead_cdb_clause

Use this clause to designate a CDB as the Lead CDB in a CDB fleet. The database property `LEAD_CDB` indicates that the current CDB is a Lead CDB, and can be found in `DATABASE_PROPERTIES` view.

There is a new parameter in `SYS_CONTEXT` named `IS_LEAD_CDB` which can be used to determine if the current session is connected to a Lead CDB in a CDB fleet.

lead_cdb_uri_clause

Use this clause to specify the connection URI for the Lead CDB in a CDB fleet. It is used to register a Member CDB with the Lead CDB of the fleet.

The database link name specified in `dblink` must exist in the CDB ROOT of the Member CDB joining the CDB fleet. It is used to synchronize PDB metadata with the Lead CDB in the fleet.

The `uri_string` specified is stored as a database property named `LEAD_CDB_URI` and can be found in `DATABASE_PROPERTIES` view.

There is a new parameter in `SYS_CONTEXT` named `IS_LEAD_CDB` which can be used to determine if the current session is connected to a Member CDB in a CDB fleet.

property_clause

Specify this clause to set or remove database properties visible through `DATABASE_PROPERTIES` or `CDB_PROPERTIES` views.

replay_upgrade_clause

Use this clause to enable or disable replay upgrade on the database.

If `UPGRADE SYNC` is `ON`, then replay upgrade and upgrade on open is enabled.

Examples

READ ONLY / READ WRITE: Example

The following statement opens the database in read-only mode:

```
ALTER DATABASE OPEN READ ONLY;
```

The following statement opens the database in read/write mode and clears the online redo logs:

```
ALTER DATABASE OPEN READ WRITE RESETLOGS;
```

Using Parallel Recovery Processes: Example

The following statement performs tablespace recovery using parallel recovery processes:

```
ALTER DATABASE
   RECOVER TABLESPACE tbs_03
   PARALLEL;
```

Adding Redo Log File Groups: Examples

The following statement adds a redo log file group with two members and identifies it with a `GROUP` parameter value of 3:

```
ALTER DATABASE
  ADD LOGFILE GROUP 3
    ('diska:log3.log' ,
     'diskb:log3.log') SIZE 50K;
```

The following statement adds a redo log file group containing two members to thread 5 (in a Real Application Clusters environment) and assigns it a `GROUP` parameter value of 4:

```
ALTER DATABASE
    ADD LOGFILE THREAD 5 GROUP 4
        ('diska:log4.log',
         'diskb:log4:log');
```

Adding Redo Log File Group Members: Example

The following statement adds a member to the redo log file group added in the previous example:

```
ALTER DATABASE
   ADD LOGFILE MEMBER 'diskc:log3.log'
   TO GROUP 3;
```

Dropping Log File Members: Example

The following statement drops one redo log file member added in the previous example:

```
ALTER DATABASE
    DROP LOGFILE MEMBER 'diskb:log3.log';
```

The following statement drops all members of the redo log file group 3:

```
ALTER DATABASE DROP LOGFILE GROUP 3;
```

Renaming a Log File Member: Example

The following statement renames a redo log file member:

```
ALTER DATABASE
    RENAME FILE 'diskc:log3.log' TO 'diskb:log3.log';
```

The preceding statement only changes the member of the redo log group from one file to another. The statement does not actually change the name of the file `diskc:log3.log` to `diskb:log3.log`. Before issuing this statement, you must change the name of the file through your operating system.

Setting the Default Type of Tablespaces: Example

The following statement specifies that subsequently created tablespaces be created as bigfile tablespaces by default:

```
ALTER DATABASE
    SET DEFAULT BIGFILE TABLESPACE;
```

Changing the Default Temporary Tablespace: Examples

The following statement makes the `tbs_05` tablespace (created in "Creating a Temporary Tablespace: Example") the default temporary tablespace of the database. This statement either establishes a default temporary tablespace if none was specified at create time, or replaces an existing default temporary tablespace with `tbs_05`:

```
ALTER DATABASE
   DEFAULT TEMPORARY TABLESPACE tbs_05;
```

Alternatively, a group of tablespaces can be defined as the default temporary tablespace by using a tablespace group. The following statement makes the tablespaces in the tablespace group `tbs_group_01` (created in "Adding a Temporary Tablespace to a Tablespace Group: Example") the default temporary tablespaces of the database:

```
ALTER DATABASE
   DEFAULT TEMPORARY TABLESPACE tbs_grp_01;
```

Creating a New Data File: Example

The following statement creates a new data file `tbs_f04.dbf` based on the file `tbs_f03.dbf`. Before creating the new data file, you must take the existing data file (or the tablespace in which it resides) offline.

```
ALTER DATABASE
    CREATE DATAFILE 'tbs_f03.dbf'
                 AS 'tbs_f04.dbf';
```

Manipulating Temp Files: Example

The following takes offline the temp file temp02.dbf created in Adding and Dropping Data Files and Temp Files: Examples and then renames the temp file:

```
ALTER DATABASE TEMPFILE 'temp02.dbf' OFFLINE;

ALTER DATABASE RENAME FILE 'temp02.dbf' TO 'temp03.dbf';
```

The statement renaming the temp file requires that you first create the file `temp03.dbf` on the operating system.

Changing the Global Database Name: Example

The following statement changes the global name of the database and includes both the database name and domain:

```
ALTER DATABASE
    RENAME GLOBAL_NAME TO demo.world.example.com;
```

Enabling and Disabling Block Change Tracking: Examples

The following statement enables block change tracking and causes Oracle Database to create a block change tracking file named `tracking_file` and overwrite the file if it already exists:

```
ALTER DATABASE
  ENABLE BLOCK CHANGE TRACKING
    USING FILE 'tracking_file' REUSE;
```

The following statement disables block change tracking and deletes the existing block change tracking file:

```
ALTER DATABASE
  DISABLE BLOCK CHANGE TRACKING;
```

Resizing a Data File: Example

The following statement attempts to change the size of data file `diskb:tbs_f5.dbf`:

```
ALTER DATABASE
    DATAFILE 'diskb:tbs_f5.dbf' RESIZE 10 M;
```

Clearing a Log File: Example

The following statement clears a log file:

```
ALTER DATABASE
    CLEAR LOGFILE 'diskc:log3.log';
```

Database Recovery: Examples

The following statement performs complete recovery of the entire database, letting Oracle Database generate the name of the next archived redo log file needed:

```
ALTER DATABASE
  RECOVER AUTOMATIC DATABASE;
```

The following statement explicitly names a redo log file for Oracle Database to apply:

```
ALTER DATABASE
    RECOVER LOGFILE 'diskc:log3.log';
```

The following statement performs time-based recovery of the database:

```
ALTER DATABASE
    RECOVER AUTOMATIC UNTIL TIME '2001-10-27:14:00:00';
```

Oracle Database recovers the database until 2:00 p.m. on October 27, 2001.

For an example of recovering a tablespace, see "Using Parallel Recovery Processes: Example".

ALTER DATABASE DICTIONARY

Purpose

To encrypt obfuscated database link passwords and use the TDE framework to manage the encryption key.

A LOB locator (pointer to the location of a large object (LOB) value) can be assigned a signature to secure the LOB.

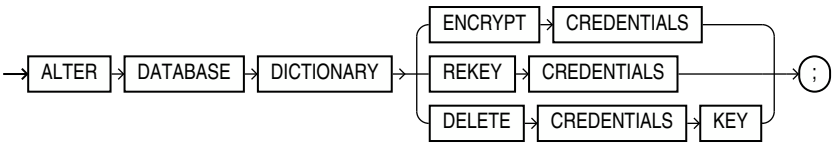
Prerequisites

- The TDE keystore must exist. The DDL first checks that the TDE:
  - Keystore exists.
  - Keystore is open.
  - Master Encryption Key exists in the TDE keystore.

    If any of the checks fail, the DDL fails. When this happens you must create a TDE keystore and provision a TDE Master Key. For more see the *Database Security Guide*.
- The instance initialization parameter `COMPATIBLE` must be set to 12.2.0.2.
- You must have `SYSKM` privileges to execute the command.

Syntax

***alter_database_dictionary*::=**



Semantics

***alter_database_dictionary_encrypt_credentials*::=**

This DDL encrypts existing and future obfuscated sensitive information in data dictionaries, for example database link passwords stored in `SYS.LINKS$`.

It performs the following actions:

- Inserts a new entry in `ENC$` corresponding to `SYS.LINK$`.
- It creates and initializes the SGA variable.
- De-obfuscates obfuscated passwords in `SYS.LINK$`.
- Encrypts the de-obfuscated passwords using the generated encryption key in `ENC$` for `SYS.LINK$`.
- Sets the flag to indicate a valid/usable dblink entry in `SYS.LINK$`.

When you use this DDL with LOB locator signature keys, they are always encrypted. A LOB locator (pointer to the location of a large object (LOB) value) can be assigned a signature to secure the LOB.

***alter_database_dictionary_rekey_credentials*::=**

This DDL is used to change the data encryption key. It is applied to `SYS.LINK$` and any other tables covered under the data dictionary encryption framework.

You can also use this DDL to regenerate the LOB locator signature key for LOB locators. If the database is in restricted mode, then Oracle Database regenerates a new LOB signature key and encrypts it with the new encryption key. If the database is in non-restricted mode, then a new signature key is not regenerated but instead, Oracle Database uses a new encryption key to encrypt the existing LOB signature key.

***alter_database_dictionary_delete_credentials_key*::=**

This DDL marks encrypted passwords unusable. That means that current password entries in `SYS.LINK$` are marked unusable. It deletes the key in `ENC$` that was used to encrypt the credentials, and clears the SGA variable to prevent future encryption.

You can also use this DDL to delete the encrypted LOB locator signature key and then regenerate a new LOB signature key in obfuscated form.

> **See Also:**
>
> *Managing Security for Application Developers* in the *Database Security Guide*

ALTER DATABASE LINK

Purpose

Use the `ALTER DATABASE LINK` statement to modify a fixed-user database link when the password of the connection or authentication user changes.

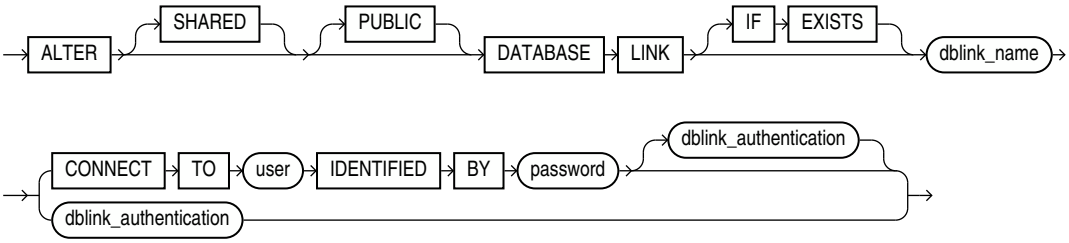
> **Note:**
>
> - You cannot use this statement to change the connection or authentication user associated with the database link. To change *`user`*, you must re-create the database link.
> - You cannot use this statement to change the password of a connection or authentication user. You must use the ALTER USER statement for this purpose, and then alter the database link with the `ALTER DATABASE LINK` statement.
> - This statement is valid only for fixed-user database links, not for connected-user or current user database links. See CREATE DATABASE LINK for more information on these two types of database links.

Prerequisites

To alter a private database link, you must have the `ALTER DATABASE LINK` system privilege. To alter a public database link, you must have the `ALTER PUBLIC DATABASE LINK` system privilege.

Syntax

***alter_database_link*::=**



dblink_authentication

Semantics

The `ALTER DATABASE LINK` statement is intended only to update fixed-user database links with the current passwords of connection and authentication users. Therefore, any clauses valid in a `CREATE DATABASE LINK` statement that do not appear in the syntax diagram above are not valid in an `ALTER DATABASE LINK` statement. The semantics of all of the clauses permitted in this statement are the same as the semantics for those clauses in `CREATE DATABASE LINK`. Refer to CREATE DATABASE LINK for this information.

IF EXISTS

Specify `IF EXISTS` to alter an existing database link.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

IDENTIFIED BY

You can set the password length to a maximum length of 1024 bytes.

Examples

The following statements show the valid variations of the `ALTER DATABASE LINK` statement:

```
ALTER DATABASE LINK private_link
  CONNECT TO hr IDENTIFIED BY hr_new_password;

ALTER PUBLIC DATABASE LINK public_link
  CONNECT TO scott IDENTIFIED BY scott_new_password;

ALTER SHARED PUBLIC DATABASE LINK shared_pub_link
  CONNECT TO scott IDENTIFIED BY scott_new_password
  AUTHENTICATED BY hr IDENTIFIED BY hr_new_password;

ALTER SHARED DATABASE LINK shared_pub_link
  CONNECT TO scott IDENTIFIED BY scott_new_password;
```

ALTER DIMENSION

Purpose

Use the `ALTER DIMENSION` statement to change the hierarchical relationships or dimension attributes of a dimension.

> **See Also:**
>
> CREATE DIMENSION and DROP DIMENSION

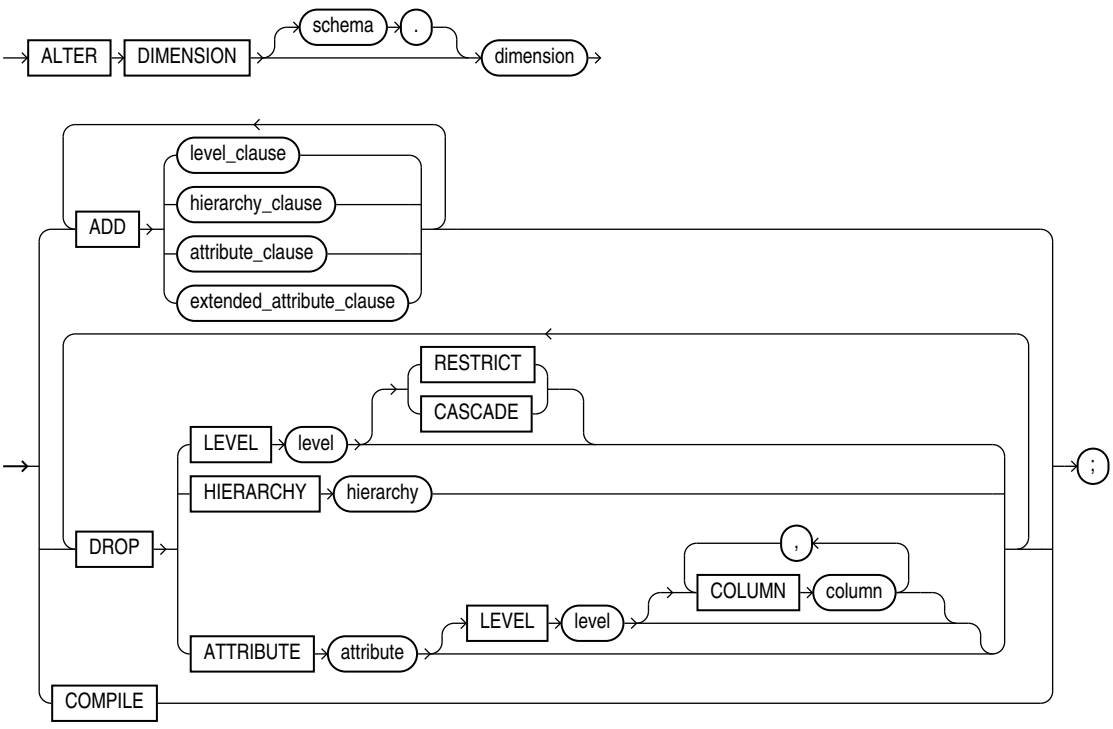
Prerequisites

The dimension must be in your schema or you must have the `ALTER ANY DIMENSION` system privilege to use this statement.

A dimension is always altered under the rights of the owner.

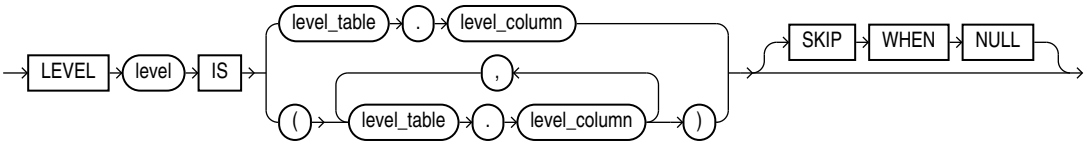
Syntax

***alter_dimension*::=**

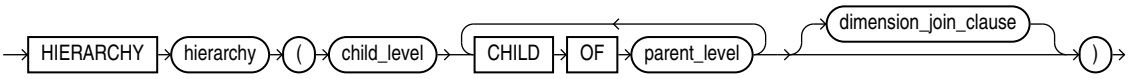


(*level_clause*::=, *hierarchy_clause*::=, *attribute_clause*::=, *extended_attribute_clause*::=)

***level_clause*::=**

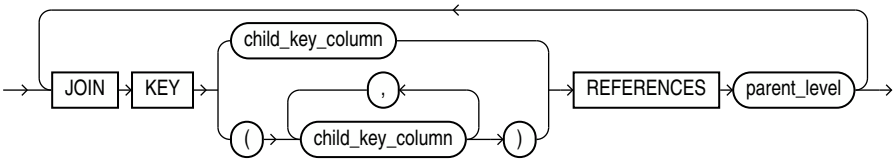


***hierarchy_clause*::=**

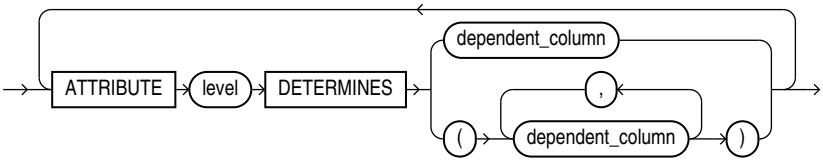


(*dimension_join_clause*::=)

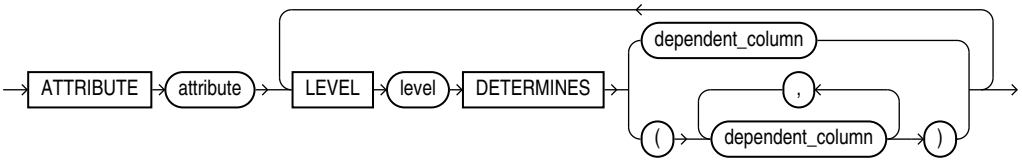
***dimension_join_clause*::=**



***attribute_clause*::=**



***extended_attribute_clause*::=**



Semantics

The following keywords, parameters, and clauses have meaning unique to `ALTER DIMENSION`. Keywords, parameters, and clauses that do not appear here have the same functionality that they have in the `CREATE DIMENSION` statement. Refer to CREATE DIMENSION for more information.

schema

Specify the schema of the dimension you want to modify. If you do not specify *schema*, then Oracle Database assumes the dimension is in your own schema.

dimension

Specify the name of the dimension. This dimension must already exist.

ADD

The `ADD` clauses let you add a level, hierarchy, or attribute to the dimension. Adding one of these elements does not invalidate any existing materialized view.

Oracle Database processes `ADD LEVEL` clauses prior to any other `ADD` clauses.

DROP

The `DROP` clauses let you drop a level, hierarchy, or attribute from the dimension. Any level, hierarchy, or attribute you specify must already exist.

Within one attribute, you can drop one or more level-to-column relationships associated with one level.

Restriction on DROP

If any attributes or hierarchies reference a level, then you cannot drop the level until you either drop all the referencing attributes and hierarchies or specify `CASCADE`.

CASCADE

Specify `CASCADE` if you want Oracle Database to drop any attributes or hierarchies that reference the level, along with the level itself.

RESTRICT

Specify `RESTRICT` if you want to prevent Oracle Database from dropping a level that is referenced by any attributes or hierarchies. This is the default.

COMPILE

Specify `COMPILE` to explicitly recompile an invalidated dimension. Oracle Database automatically compiles a dimension when you issue an `ADD` clause or `DROP` clause. However, if you alter an object referenced by the dimension (for example, if you drop and then re-create a table referenced in the dimension), Oracle Database invalidates, and you must recompile it explicitly.

Examples

Modifying a Dimension: Examples

The following examples modify the `customers_dim` dimension in the sample schema `sh`:

```
ALTER DIMENSION customers_dim
   DROP ATTRIBUTE country;

ALTER DIMENSION customers_dim
   ADD LEVEL zone IS customers.cust_postal_code
   ADD ATTRIBUTE zone DETERMINES (cust_city);
```

ALTER DISKGROUP

> **Note:**
>
> This SQL statement is valid only if you are using Oracle ASM and you have started an Oracle ASM instance. You must issue this statement from within the Oracle ASM instance, not from a normal database instance. For information on starting an Oracle ASM instance, refer to *Oracle Automatic Storage Management Administrator's Guide*.

Purpose

The `ALTER DISKGROUP` statement lets you perform a number of operations on a disk group or on the disks in a disk group.

> **See Also:**
>
> - CREATE DISKGROUP for information on creating disk groups
> - *Oracle Automatic Storage Management Administrator's Guide* for information on Oracle ASM and using disk groups to simplify database administration

Prerequisites

You must have an Oracle ASM instance started from which you issue this statement. The disk group to be modified must be mounted.

You can issue all `ALTER DISKGROUP` clauses if you have the `SYSASM` system privilege. You can issue specific clauses as follows:

- The `SYSOPER` privilege permits the following subset of the `ALTER DISKGROUP` operations: *`diskgroup_availability`*, *`rebalance_diskgroup_clause`*, *`check_diskgroup_clause`* (without the `REPAIR` option).
- If you are connected as `SYSDBA`, you have limited privileges to use this statement. The following operations are always granted to users connected as `SYSDBA`:
  - `ALTER DISKGROUP ... ADD DIRECTORY`
  - `ALTER DISKGROUP ... ADD/ALTER/DROP TEMPLATE` (nonsystem templates only)
  - `ALTER DISKGROUP ... ADD USERGROUP`
  - `SELECT`
  - `SHOW PARAMETER`

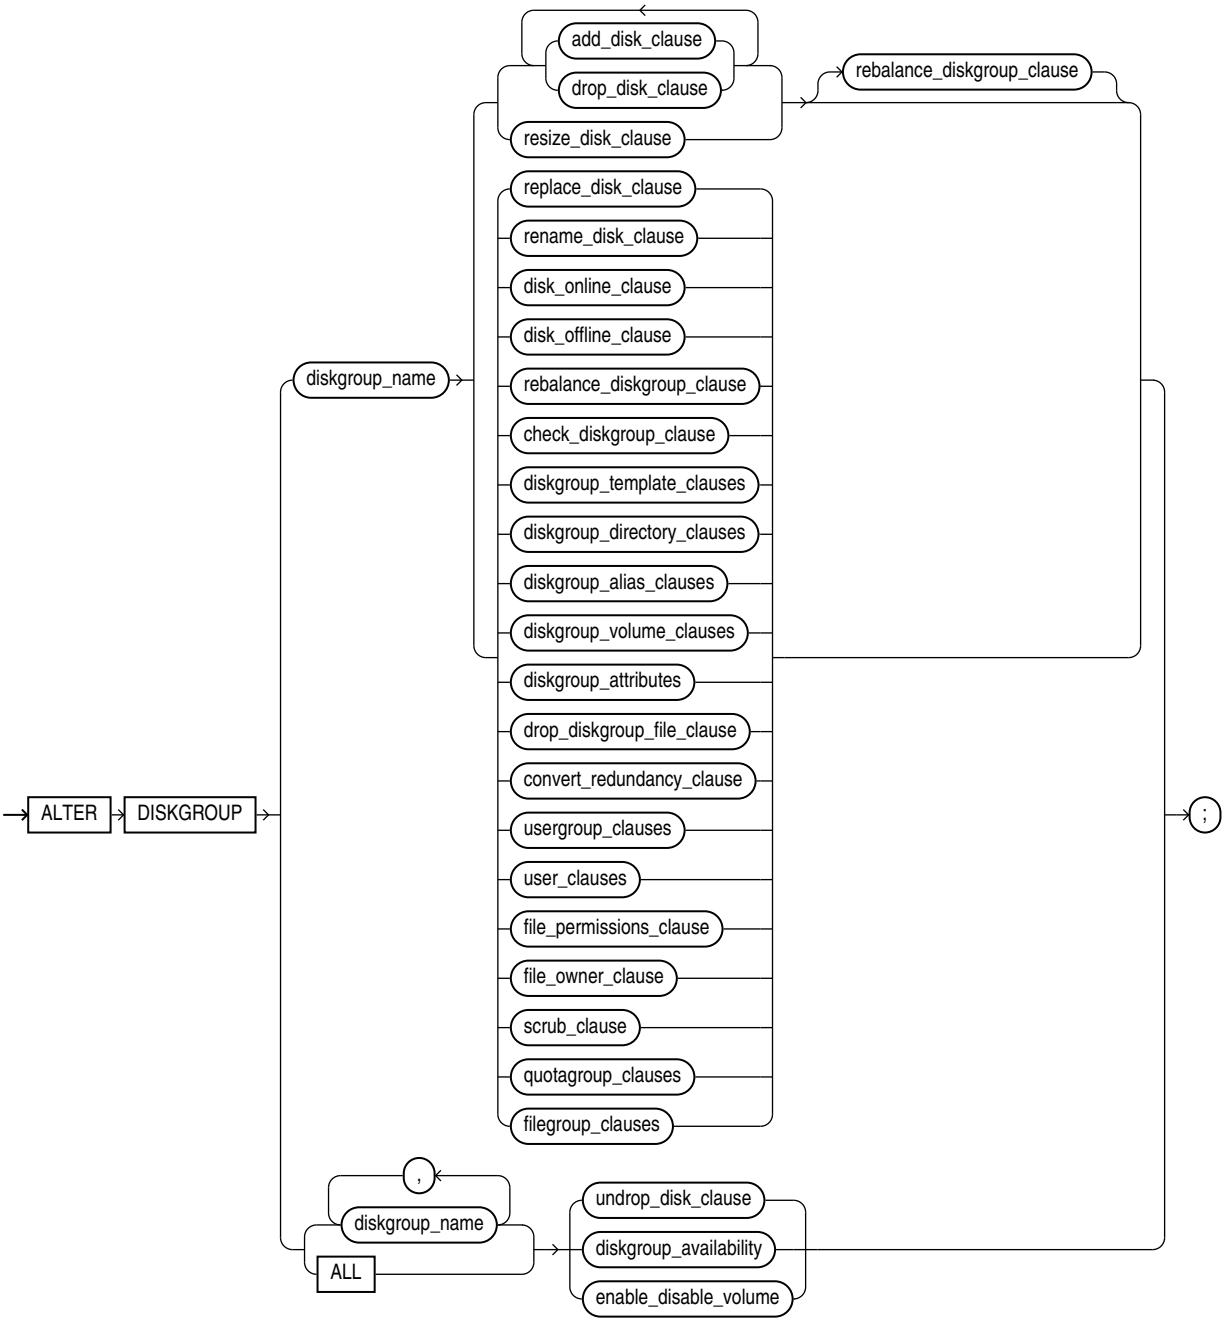
Table 10-1 shows additional privileges granted to users connected as `SYSDBA` under the conditions shown:

Table 10-1 Conditional Diskgroup Privileges for SYSDBA

ALTER DISKGROUP Operation	Condition
DROP FILE	User must have read-write permission on the file.
ADD ALIAS	User must have read-write permission on the related file.
RENAME ALIAS	User must have read-write permission on the related file.
DROP ALIAS	User must have read-write permission on the related file.
RENAME DIRECTORY	Directory must contain only aliases and no files. User must have DROP ALIAS permissions on all aliases under the directory.
DROP DIRECTORY	Directory must contain only aliases and no files. User must have DROP ALIAS permissions on all aliases under the directory.
DROP USERGROUP	User must be the owner of the user group.
MODIFY USERGROUP ADD MEMBER	User must be the owner of the user group.
MODIFY USERGROUP DROP MEMBER	User must be the owner of the user group.
SET PERMISSION	User must be the owner of the file.
SET OWNER GROUP	User must be the owner of the file and a member of the user group.

Syntax

***alter_diskgroup*::=**



(*add_disk_clause*::=, *drop_disk_clause*::=, *resize_disk_clause*::=, *replace_disk_clause*::=, *rename_disk_clause*::=, *disk_online_clause*::=, *disk_offline_clause*::=, *rebalance_diskgroup_clause*::=, *check_diskgroup_clause*::=, *diskgroup_template_clauses*::=, *diskgroup_directory_clauses*::=, *diskgroup_alias_clauses*::=, *diskgroup_volume_clauses*::=, *diskgroup_attributes*::=, *modify_diskgroup_file*::=, *drop_diskgroup_file_clause*::=, *convert_redundancy_clause*::=, *usergroup_clauses*::=, *user_clauses*::=, *file_permissions_clause*::=, *file_owner_clause*::=, *scrub_clause*::=, *quotagroup_clauses*::=,

Semantics

diskgroup_name

Specify the name of the disk group you want to modify. To determine the names of existing disk groups, query the `V$ASM_DISKGROUP` dynamic performance view.

add_disk_clause

Use this clause to add one or more disks to the disk group and specify attributes for the newly added disk. Oracle ASM automatically rebalances the disk group as part of this operation.

You cannot use this clause to change the failure group of a disk. Instead you must drop the disk from the disk group and then add the disk back into the disk group as part of the new failure group.

To determine the names of the disks already in this disk group, query the `V$ASM_DISK` dynamic performance view.

QUORUM | REGULAR

The semantics of these keyword are the same as the semantics in a `CREATE DISKGROUP` statement. See QUORUM | REGULAR for more information on these keywords.

You cannot change this qualifier for an existing disk or disk group. Therefore, you cannot specify in this clause a keyword different from the keyword that was specified when the disk group was created.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for more information about the use of these keywords

FAILGROUP Clause

Use this clause to assign the newly added disk to a failure group. If you omit this clause and you are adding the disk to a normal or high redundancy disk group, then Oracle Database automatically adds the newly added disk to its own failure group. The implicit name of the failure group is the same as the operating system independent disk name (see "NAME Clause").

You cannot specify this clause if you are creating an external redundancy disk group.

qualified_disk_clause

This clause has the same semantics in `CREATE DISKGROUP` and `ALTER DISKGROUP` statements. For complete information on this clause, refer to *qualified_disk_clause* in the documentation on `CREATE DISKGROUP`.

drop_disk_clause

Use this clause to drop one or more disks from the disk group.

DROP DISK

The `DROP DISK` clause lets you drop one or more disks from the disk group and automatically rebalance the disk group. When you drop a disk, Oracle ASM relocates all the data from the disk and clears the disk header so that it no longer is part of the disk group. The disk header is not cleared if you specify the `FORCE` keyword.

Specify *`disk_name`* as shown in the `NAME` column of the `V$ASM_DISK` dynamic performance view.

If a disk to be dropped is a quorum disk or belongs to a quorum failure group, then you must specify `QUORUM` in order to drop the disk. See QUORUM | REGULAR.

DROP DISKS IN FAILGROUP

The `DROP DISKS IN FAILGROUP` clause lets you drop all the disks in the specified failure group. The behavior is otherwise the same as that for the `DROP DISK` clause.

If the specified failure group is a quorum failure group, then you must specify the `QUORUM` keyword in order to drop the disks. See QUORUM | REGULAR.

FORCE | NOFORCE

These keywords let you specify when the disk is considered to be no longer part of the disk group. The default and recommended setting is `NOFORCE`.

- When you specify `NOFORCE`, Oracle ASM reallocates all of the extents of the disk to other disks and then expels the disk from the disk group and rebalances the disk group.

> **Note:**
>
> `DROP DISK ... NOFORCE` returns control to the user before the disk can be safely reused or removed from the system. To ensure that the drop disk operation has completed, query the `V$ASM_DISK` view to verify that `HEADER_STATUS` has the value `FORMER`. Do not attempt to remove or reuse a disk if `STATE` has the value `DROPPING`. Query the `V$ASM_OPERATION` view for approximate information on how long it will take to complete the rebalance resulting from dropping the disk.If you also specify `REBALANCE ... WAIT` (see *rebalance_diskgroup_clause*), then the statement will not return until the rebalance operation is complete and the disk has been cleared. However, you should always verify that the `HEADER_STATUS` column of `V$ASM_DISK` is `FORMER`, because of the unlikely event the rebalance operations fails.

- When you specify `FORCE`, Oracle Database expels the disk from the disk group immediately. It then reconstructs the data from the redundant copies on other disks, reallocates the data to other disks, and rebalances the disk group.

  The `FORCE` clause can be useful, for example, if Oracle ASM can no longer read the disk to be dropped. However, it is more time consuming than a `NOFORCE` drop, and it can leave portions of a file with reduced protection. You cannot specify `FORCE` for an external redundancy disk group at all, because in the absence of redundant data on the disk, Oracle ASM must read the data from the disk before it can be dropped.

The rebalance operation invoked when a disk is dropped is time consuming, whether or not you specify `FORCE` or `NOFORCE`. You can monitor the progress by querying the `V$ASM_OPERATION` dynamic performance view. Refer to *rebalance_diskgroup_clause* for more information on rebalance operations.

resize_disk_clause

Use this clause to specify a new size for every disk in a disk group. This clause lets you override the size returned by the operating system or the size you specified previously for the disks.

SIZE

Specify the new size in kilobytes, megabytes, gigabytes, or terabytes. You cannot specify a size greater than the capacity of the disk. If you specify a size smaller than the disk capacity, then you limit the amount of disk space Oracle ASM will use. If you omit this clause, then Oracle ASM attempts programatically to determine the size of the disks.

replace_disk_clause

Use this clause to replace one or more disks in the disk group. This clause allows you to replace disks with a single operation, which is more efficient than dropping and adding each disk.

For *`disk_name`*, specify the name of the disk you want to replace. This name is assigned to the replacement disk. You can view disk names by querying the `NAME` column of the `V$ASM_DISK` dynamic performance view.

For *`path_name`*, specify the full path name for the replacement disk.

FORCE

Specify FORCE if you want Oracle ASM to add the replacement disk to the disk group even if the replacement disk is already a member of a disk group.

> **Note:**
>
> Using FORCE in this way may destroy existing disk groups.

NOFORCE

Specify NOFORCE if you want Oracle ASM to return an error if the replacement disk is already a member of a disk group. NOFORCE is the default.

POWER

The POWER clause has the same semantics here as for a manual rebalancing of a disk group, except that the power value cannot be set to 0. See POWER.

WAIT | NOWAIT

The WAIT and NOWAIT keywords have the same semantics here as for a manual rebalancing of a disk group. See WAIT | NOWAIT.

rename_disk_clause

Use this clause to rename one or more disks in the disk group. The disk group must be in the MOUNT RESTRICTED state and all disks in the disk group must be online.

RENAME DISK

Specify this clause to rename one or more disks. For each disk, specify the *old_disk_name* and *new_disk_name*. If *new_disk_name* already exists, then this operation fails.

RENAME DISKS ALL

Specify this clause to rename all disks in the disk group to a name of the form *diskgroupname_####*, where *####* is the disk number. Disk names that are already in the *diskgroupname_####* format are not changed.

disk_online_clause

Use this clause to bring one or more disks online and rebalance the disk group.

ONLINE DISK

The ONLINE DISK clause lets you bring one or more specified disks online and rebalance the disk group.

Specify *disk_name* as shown in the NAME column of the V$ASM_DISK dynamic performance view.

The QUORUM and REGULAR keywords have the same semantics here as they have when adding a disk to a disk group. See QUORUM | REGULAR.

ONLINE DISKS IN FAILGROUP

The ONLINE DISKS IN FAILGROUP clause lets you bring all disks in the specified failure group online and rebalance the disk group.

If the specified failure group is a quorum failure group, then you must specify the QUORUM keyword in order to bring the disks online. See QUORUM | REGULAR.

ALL

The ALL clause lets you bring all disks in the disk group online and rebalance the disk group.

POWER

The POWER clause has the same semantics here as for a manual rebalancing of a disk group. See POWER

WAIT | NOWAIT

The WAIT and NOWAIT keywords have the same semantics here as for a manual rebalancing of a disk group. See WAIT | NOWAIT.

disk_offline_clause

Use the *disk_offline_clause* to take one or more disks offline. This clause fails if the redundancy level of the disk group would be violated by taking the specified disks offline.

OFFLINE DISK

The OFFLINE DISK clause lets you take one or more specified disks offline.

Specify *disk_name* as shown in the NAME column of the V$ASM_DISK dynamic performance view.

The QUORUM and REGULAR keywords have the same semantics here as they have when adding a disk to a disk group. See QUORUM | REGULAR.

OFFLINE DISKS IN FAILGROUP

The OFFLINE DISKS IN FAILGROUP clause lets you take all disks in the specified failure group offline.

If the specified failure group is a quorum failure group, then you must specify the QUORUM keyword in order to take the disks offline. See QUORUM | REGULAR.

timeout_clause

By default, Oracle ASM drops a disk shortly after it is taken offline. You can delay this operation by specifying the *timeout_clause*, which gives you the opportunity to repair the disk and bring it back online. You can specify the timeout value in units of minute or hour. If you omit the unit, then the default is hour.

You can change the timeout period by specifying this clause multiple times. Each time you specify it, Oracle ASM measures the time from the most recent previous *disk_offline_clause* while the disk group is mounted. To learn how much time remains before Oracle ASM will drop an offline disk, query the REPAIR_TIMER column of V$ASM_DISK.

This clause overrides any previous setting of the disk_repair_time attribute. Refer to Table 13-2 for more information about disk group attributes.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for more information about taking Oracle ASM disks online and offline

WAIT | NOWAIT

Specify `WAIT` for all disk handles to close all instances before offline returns. The default wait timeout is 300 seconds (5 minutes).

rebalance_diskgroup_clause

Use this clause to manually rebalance the disk group. During a rebalance operation, Oracle ASM redistributes data files evenly across all drives. This clause is rarely necessary, because Oracle ASM allocates files evenly and automatically rebalances disk groups when the storage configuration changes. However, it is useful if you want to perform a controlled rebalance operation. It allows you to include or exclude certain phases of a rebalance operation, pause and restart a rebalance operation, and adjust the power of a rebalance operation.

WITH | WITHOUT

A rebalance operation consists of the following phases: `RESTORE` (includes the `RESYNC`, `RESILVER`, or `REBUILD` phases), `BALANCE`, `PREPARE`, and `COMPACT`.

You can use the `WITH` or `WITHOUT` clause to instruct Oracle ASM to include or exclude specific phases of a rebalance operation. For example, if you have time constraints, you can include only the `RESTORE` phase. Or, if you are using flash storage disk groups or disk groups with flash cache, you can exclude the `COMPACT` phase, which is not beneficial for such disk groups.

- Use the `WITH` clause to include only the specified phases of a rebalance operation. You can specify any of phases `RESTORE`, `BALANCE`, `PREPARE`, and `COMPACT`. It is acceptable, but not necessary, to specify `RESTORE`, because the `RESTORE` phase always occurs.
- Use the `WITHOUT` clause to exclude the specified phases of a rebalance operation. You can specify any of the phases `BALANCE`, `PREPARE`, and `COMPACT`. You cannot specify `RESTORE`, because the `RESTORE` phase must always occur.

The order in which you specify multiple phases in the `WITH` or `WITHOUT` clause does not matter. Oracle ASM will perform the phases of the rebalance operation in the proper order. You cannot specify the `RESYNC`, `RESILVER`, or `REBUILD` phases; they are part of the `RESTORE` phase.

If you omit the `WITH` and `WITHOUT` clauses, then Oracle ASM performs all phases of the rebalance operation.

You can monitor the progress of the rebalance operation by querying the `V$ASM_OPERATION` dynamic performance view.

See *Oracle Automatic Storage Management Administrator's Guide* for more information on the phases of a rebalance operation.

POWER

This clause lets you specify the power, or speed, of the rebalance operation. It also lets you stop the rebalance operation.

For *`integer`*, specify a value from `0` to `1024`:

- A value of `1` through `1024` specifies the power at which Oracle ASM is to perform the rebalance operation, with `1` representing the lowest possible power and `1024` representing the highest possible power.
- A value of `0` stops an active rebalance operation. No further rebalancing will occur until the start of another manual or automatic rebalance operation on the disk group, and at that time the rebalance operation will start from the beginning. If you would like to have the option of later resuming the rebalance operation from where it left off, then instead stop the

rebalance operation by specifying `MODIFY POWER 0`. See the clause MODIFY POWER for more information.

If you omit the `POWER` clause, then the default power is determined as follows:

- For flex disk groups, Oracle ASM rebalances each file group according the value of its `POWER_LIMIT` property. If the `POWER_LIMIT` property is not set for a file group, then Oracle ASM uses the value of the `ASM_POWER_LIMIT` initialization parameter for the file group.
- For all other types of disk groups, if you omit the `POWER` clause, then Oracle ASM rebalances the disk group according to the value of the `ASM_POWER_LIMIT` initialization parameter.

WAIT | NOWAIT

Use this clause to specify when, in the course of the rebalance operation, control should be returned to the user.

- Specify `WAIT` if you want control returned to the user after the rebalance operation has finished. You can explicitly terminate a rebalance operation running in `WAIT` mode, although doing so does not undo any completed disk add, drop, or resize operations in the same statement.
- Specify `NOWAIT` if you want control returned to the user immediately after the statement is issued. This is the default.

MODIFY POWER

Use this clause to pause, resume, or change the power of an active rebalance operation.

You can specify *`integer`* as follows:

- Specify `0` to pause the rebalance operation. When you pause a rebalance operation in this manner, you can subsequently resume the operation from the phase where it left off by issuing an `ALTER DISKGROUP ... MODIFY POWER ...` statement. If you subsequently start a manual rebalance operation on the disk group using the clause POWER, or an automatic rebalance operation for the disk group occurs, then the rebalance operation will start at the beginning.
- Specify `1` through `1024` to specify the power of the rebalance operation, with `1` representing the lowest possible power and `1024` representing the highest possible power. If a rebalance operation is running, then Oracle ASM changes the power without interrupting the operation. If a rebalance operation was previously paused with the `MODIFY POWER 0` clause, then the rebalance operation resumes at the specified power.
- Omit *`integer`* to specify the default power. If a rebalance operation is running, then Oracle ASM changes the power to the default power without interrupting the operation. If a rebalance operation was previously paused with the `MODIFY POWER 0` clause, then the rebalance operation resumes at the default power. Refer to the clause POWER for information on how the default power is determined.

See Also:

- *Oracle Database Reference* for more information on the `ASM_POWER_LIMIT` initialization parameter and the `V$ASM_OPERATION` dynamic performance view
- Rebalancing a Disk Group: Example

check_diskgroup_clause

The *check_diskgroup_clause* lets you verify the internal consistency of Oracle ASM disk group metadata. The disk group must be mounted. Oracle ASM displays summary errors and writes the details of the detected errors in the alert log.

The CHECK keyword performs the following operations:

- Checks the consistency of the disk.
- Cross checks all the file extent maps and allocation tables for consistency.
- Checks that the alias metadata directory and file directory are linked correctly.
- Checks that the alias directory tree is linked correctly.
- Checks that Oracle ASM metadata directories do not have unreachable allocated blocks.

REPAIR | NOREPAIR

This clause lets you instruct Oracle ASM whether or not to attempt to repair any errors found during the consistency check. The default is NOREPAIR. The NOREPAIR setting is useful if you want to be alerted to any inconsistencies but do not want Oracle ASM to take any automatic action to resolve them.

Deprecated Clauses

In earlier releases, you could specify CHECK for ALL, DISK, DISKS IN FAILGROUP, or FILE. Those clauses have been deprecated as they are no longer needed. If you specify them, then their behavior is the same as in earlier releases and a message is added to the alert log. However, Oracle recommends that you do not introduce these clauses into your new code, as they are scheduled for desupport. The deprecated clauses are these:

- ALL checks all disks and files in the disk group.
- DISK checks one or more specified disks in the disk group.
- DISKS IN FAILGROUP checks all disks in a specified failure group.
- FILE checks one or more specified files in the disk group. You must use one of the reference forms of the filename. Refer to *ASM_filename* for information on the reference forms of Oracle ASM filenames.

diskgroup_template_clauses

A template is a named collection of attributes. When you create a disk group, Oracle ASM associates a set of initial system default templates with that disk group. The attributes defined by the template are applied to all files in the disk group. Table 10-2 lists the system default templates and the attributes they apply to the various file types. The *diskgroup_template_clauses* described following the table let you change the template attributes and create new templates.

You cannot use this clause to change the attributes of a disk group file after it has been created. Instead, you must use Recovery Manager (RMAN) to copy the file into a new file with the new attributes.

Table 10-2 Oracle Automatic Storage Management System Default File Group Templates

Template Name	File Type	Mirroring Level in External Redundancy Disk Groups	Mirroring Level in Normal Redundancy Disk Groups	Mirroring Level in High Redundancy Disk Groups	Striped
CONTROLFILE	Control files	Unprotected	3-way mirror	3-way mirror	FINE
DATAFILE	Data Files and copies	Unprotected	2-way mirror	3-way mirror	COARSE
ONLINELOG	Online logs	Unprotected	2-way mirror	3-way mirror	COARSE
ARCHIVELOG	Archive logs	Unprotected	2-way mirror	3-way mirror	COARSE
TEMPFILE	Temp files	Unprotected	2-way mirror	3-way mirror	COARSE
BACKUPSET	Data File backup pieces, data file incremental backup pieces, and archive log backup pieces	Unprotected	2-way mirror	3-way mirror	COARSE
PARAMETERFILE	SPFILE	Unprotected	2-way mirror	3-way mirror	COARSE
DATAGUARDCONFIG	Disaster recovery configurations (used in standby databases)	Unprotected	2-way mirror	3-way mirror	COARSE
FLASHBACK	Flashback logs	Unprotected	2-way mirror	3-way mirror	COARSE
CHANGETRACKING	Block change tracking data (used during incremental backups)	Unprotected	2-way mirror	3-way mirror	COARSE
DUMPSET	Data Pump dumpset	Unprotected	2-way mirror	3-way mirror	COARSE
XTRANSPORT	Cross-platform converted data file	Unprotected	2-way mirror	3-way mirror	COARSE
AUTOBACKUP	Automatic backup files	Unprotected	2-way mirror	3-way mirror	COARSE
ASMPARAMETERFILE	SPFILE	Unprotected	2-way mirror	3-way mirror	COARSE
OCRFILE	Oracle Cluster Registry file	Unprotected	2-way mirror	3-way mirror	COARSE

ADD TEMPLATE

Use this clause to add one or more named templates to a disk group. To determine the names of existing templates, query the V$ASM_TEMPLATE dynamic performance view.

MODIFY TEMPLATE

Use this clause to modify the attributes of a system default or user-defined disk group template. Only the specified attributes are altered. Unspecified properties retain their current values.

> **Note:**
>
> In earlier releases, the keywords ALTER TEMPLATE were used instead of MODIFY TEMPLATE. The ALTER keyword is still supported for backward compatibility, but is replaced with MODIFY for consistency with other Oracle SQL.

template_name

Specify the name of the template to be added or modified. The maximum length of a template name is 30 characters. The name must satisfy the requirements listed in "Database Object Naming Rules ".

redundancy_clause

Specify `PARITY` for single parity protection for write-once file types like archive logs and backup sets. If parity protection is not specified, the default redundancy for write-once file types will continue to be derived from system templates.

Specify `DOUBLE` for double parity for write-once file types like archive logs and backup sets. If parity protection is not specified, the default redundancy for write-once file types will continue to be derived from system templates.

Example:

```
ALTER DISKGROUP <diskgroup_name> MODIFY TEMPLATE <archivelog> ATTRIBUTE (DOUBLE)
```

The redundancy of write-once file types may be changed to support parity protection later as needed.

Specify the redundancy level of the newly added or modified template:

- `MIRROR`: Files to which this template are applied are protected by mirroring their data blocks. In normal redundancy disk groups, each primary extent has one mirror extent (2-way mirroring). For high redundancy disk groups, each primary extent has two mirror extents (3-way mirroring). You cannot specify `MIRROR` for templates in external redundancy disk groups.
- `HIGH`: Files to which this template are applied are protected by mirroring their data blocks. Each primary extent has two mirror extents (3-way mirroring) for both normal redundancy and high redundancy disk groups. You cannot specify `HIGH` for templates in external redundancy disk groups.
- `UNPROTECTED`: Files to which this template are applied are not protected by Automated Storage Management from media failures. Disks taken offline, either through system action or by user command, can cause loss of unprotected files. `UNPROTECTED` is the only valid setting for external redundancy disk groups. `UNPROTECTED` may not be specified for templates in high redundancy disk groups. Oracle discourages the use of unprotected files in high and normal redundancy disk groups.
- `PARITY`: Specify the property `PARITY` for single parity for write-once file types only.

If you omit the redundancy clause, then the value defaults to `MIRROR` for a normal redundancy disk group, `HIGH` for a high redundancy disk group, and `UNPROTECTED` for an external redundancy disk group.

striping_clause

Specify how the files to which this template are applied will be striped:

- `FINE`: Files to which this template are applied are striped every 128KB. This striping mode is not valid for an Oracle ASM spfile.
- `COARSE`: Files to which this template are applied are striped every 1MB. This is the default value.

DROP TEMPLATE

Use this clause to drop one or more templates from the disk group. You can use this clause to drop only user-defined templates, not system default templates.

diskgroup_directory_clauses

Before you can create alias names for Oracle ASM filenames (see *diskgroup_alias_clauses*), you must specify the full directory structure in which the alias name will reside. The *diskgroup_directory_clauses* let you create and manipulate such a directory structure.

ADD DIRECTORY

Use this clause to create a new directory path for hierarchically named aliases. Use a slash (/) to separate components of the directory. Each directory component can be up to 48 bytes in length and must not contain the slash character. You cannot use a space for the first or last character of any component. The total length of the directory path cannot exceed 256 bytes minus the length of any alias name you intend to create in this directory (see *diskgroup_alias_clauses*).

DROP DIRECTORY

Use this clause to drop a directory for hierarchically named aliases. Oracle ASM will not drop the directory if it contains any alias definitions unless you also specify `FORCE`. This clause is not valid for dropping directories created as part of a system alias. Such directories are labeled with the value `Y` in the `SYSTEM_CREATED` column of the `V$ASM_ALIAS` dynamic performance view.

RENAME DIRECTORY

Use this clause to change the name of a directory for hierarchically named aliases. This clause is not valid for renaming directories created as part of a system alias. Such directories are labeled with the value `Y` in the `SYSTEM_CREATED` column of the `V$ASM_ALIAS` dynamic performance view.

diskgroup_alias_clauses

When an Oracle ASM file is created, either implicitly or by user specification, Oracle ASM assigns to the file a fully qualified name ending in a dotted pair of numbers (see *file_specification*). The *diskgroup_alias_clauses* let you create more user-friendly alias names for the Oracle ASM filenames. You cannot specify an alias name that ends in a dotted pair of numbers, as this format is indistinguishable from an Oracle ASM filename.

Before specifying this clause, you must first create the directory structure appropriate for your naming conventions (see *diskgroup_directory_clauses*). The total length of the alias name, including the directory prefix, is limited to 256 bytes. Alias names are case insensitive but case retentive.

ADD ALIAS

Use this clause to create an alias name for an Oracle ASM filename. The *alias_name* consists of the full directory path and the alias itself. To determine the names of existing Oracle ASM aliases, query the `V$ASM_ALIAS` dynamic performance view. Refer to *ASM_filename* for information on Oracle ASM filenames.

DROP ALIAS

Use this clause to remove an alias name from the disk group directory. Each alias name consists of the full directory path and the alias itself. The underlying file to which the alias refers remains unchanged.

RENAME ALIAS

Use this clause to change the name of an existing alias. The *alias_name* consists of the full directory path and the alias itself.

Restriction on Dropping and Renaming Aliases

You cannot drop or rename a system-generated alias. To determine whether an alias was system generated, query the SYSTEM_CREATED column of the V$ASM_ALIAS dynamic performance view.

diskgroup_volume_clauses

Use these clauses to manipulate logical Oracle ASM Dynamic Volume Manager (Oracle ADVM) volumes corresponding to physical volume devices. To use these clauses, Oracle ASM must be started and the disk group being modified must be mounted.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for more information about disk group volumes, including examples

add_volume_clause

Use this clause to add a volume to the disk group.

For *asm_volume*, specify the name of the volume. The name can contain only alphanumeric characters and the first character must be alphabetic. The maximum length of the name is platform dependent. Refer to *Oracle Automatic Storage Management Administrator's Guide* for more information.

For *size_clause*, specify the size of the Oracle ADVM volume. The Oracle ASM instance determines whether sufficient space exists to create the volume. If sufficient space does not exist, then the Oracle ASM instance returns an error. If sufficient space does exist, then all nodes in the cluster with an Oracle ASM instance running and the disk group mounted are notified of the addition. Oracle ASM creates and enables on those nodes a volume device that can be used to create and mount file systems.

The following optional settings are also available:

- In the *redundancy_clause*, specify the redundancy level of the Oracle ADVM volume. You can specify this clause only when creating a volume in a normal redundancy disk group. You can specify the following volume redundancy levels:
  - MIRROR: 2-way mirroring of the volume. This is the default.
  - HIGH: 3-way mirroring of the volume.
  - UNPROTECTED: No mirroring of the volume.

  You cannot specify the *redundancy_clause* when creating a volume in a high redundancy disk group or an external redundancy disk group. If you do so, then an error will result. In high redundancy disk groups, Oracle Database automatically sets the volume redundancy to HIGH (3-way mirroring). In external redundancy disk groups, Oracle Database automatically sets the volume redundancy to UNPROTECTED (no mirroring).
- In the STRIPE_WIDTH clause, specify a stripe width for the Oracle ADVM volume. The valid range is from 4KB to 1MB, at intervals of the power of 2. The default value is 128K.

- In the `STRIPE_COLUMNS` clause, specify the number of stripes in a stripe set of the Oracle ADVM volume. The valid range is 1 to 8. The default is 4. If `STRIPE_COLUMNS` is set to 1, then striping becomes disabled. In this case, the stripe width is the extent size of the volume. This volume extent size is 64 times the allocation unit (AU) size of the disk group.

modify_volume_clause

Use this clause to modify the characteristics of an existing Oracle ADVM volume. You must specify at least one of the following clauses:

- In the `MOUNTPATH` clause, specify the mountpath name associated with the volume. The *`mountpath_name`* can be up to 1024 characters.
- In the `USAGE` clause, specify the usage name associated with the volume. The *`usage_name`* can be up to 30 characters.

RESIZE VOLUME Clause

Use this clause to change the size of an existing Oracle ADVM volume. In an Oracle ASM cluster, the new size is propagated to all nodes. If an Oracle Advanced Cluster File System (ACFS) exists on the volume, then you must use the `acfsutil size` command instead of the `ALTER DISKGROUP` statement.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for more information about the `acfsutil size` command

DROP VOLUME Clause

Use this clause to remove the Oracle ASM file that is the storage container for an existing Oracle ADVM volume. In an Oracle ASM cluster, all nodes with an Oracle ASM instance running and with this disk group open are notified of the drop operation, which results in removal of the volume device. If the volume file is open, then this clause returns an error.

diskgroup_attributes

Use this clause to specify attributes for the disk group. Table 13-2 lists the attributes you can set with this clause. Refer to the `CREATE DISKGROUP` "ATTRIBUTE Clause " for information on the behavior of this clause.

drop_diskgroup_file_clause

Use this clause to drop a file from the disk group. Oracle ASM also drops all aliases associated with the file being dropped. You must use one of the reference forms of the filename. Most Oracle ASM files do not need to be manually deleted because, as Oracle Managed Files, they are removed automatically when they are no longer needed. Refer to *ASM_filename* for information on the reference forms of Oracle ASM filenames.

You cannot drop a disk group file it if is the spfile that was used to start up the current instance or any instance in the Oracle ASM cluster.

convert_redundancy_clause

You can use this clause to convert a `NORMAL REDUNDANCY` or `HIGH REDUNDANCY` disk group to a `FLEX REDUNDANCY` disk group. The disk group must have at least three failure groups before you start the conversion.

usergroup_clauses

Use these clauses to add a user group to the disk group, remove a user group from the disk group, or to add a member to or drop a member from an existing user group.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for detailed information about user groups and members, including examples

ADD USERGROUP

Use this clause to add a user group to the disk group. You must have `SYSASM` or `SYSDBA` privilege to create a user group. The maximum length of a user group name is 63 bytes. If you specify the user name, then it must be in the OS password file and its length cannot exceed 32 characters.

MODIFY USERGROUP

Use these clauses to add a member to or drop a member from an existing user group. You must be an Oracle ASM administrator (with SYSASM privilege) or the creator (with SYSDBA privilege) of the user group to use these clauses. The user name must be an existing user in the OS password file.

DROP USERGROUP

Use this clause to drop an existing user group from the disk group. You must be an Oracle ASM administrator (with SYSASM privilege) or the creator (with SYSDBA privilege) of the user group to use this clause. Dropping a user group may leave a disk group file without a valid user group. In this case, you can update the disk group file manually to add a new, valid group using the *file_permissions_clause*.

user_clauses

Use these clauses to add a user to, drop a user from, or replace a user in a disk group.

> **Note:**
>
> When administering users with SQL*Plus, the users must be existing operating system users and their user names must have corresponding operating system user IDs. However, only users in the same cluster as the Oracle ASM instance can be validated.

ADD USER

Use this clause to add one or more operating system (OS) users to an Oracle ASM disk group and give those users access privileges on the disk group. A user name must be an existing

user in the OS password file and its length cannot exceed 32 characters. If a specified user already exists in the disk group, as shown by V$ASM_USER, then the command records an error and continues to add other users, if any have been specified. This command is seldom needed, because the OS user running the database instance is added to a disk group automatically when the instance accesses the disk group. However, this clause is useful when adding users that are not associated with a particular database instance.

DROP USER

Use this clause to drop one or more users from the disk group. If a specified user is not in the disk group, then this clause records an error and continues to drop other users, if any are specified. If the user owns any files, then you must specify the CASCADE keyword, which drops the user and all the user's files. If any files owned by the user are open, then DROP USER CASCADE fails with an error.

To delete a user without deleting the files owned by that user, change the owner of each of these files to another user and then issue an ALTER DISKGROUP ... DROP USER statement on the user. Alternatively, you can issue an ALTER DISKGROUP ... REPLACE USER statement to replace the user you want to drop with a user that currently does not exist in the disk group. This operation has the side effect of making the new user the owner of files that were previously owned by the dropped user.

REPLACE USER

Use this clause to replace *old_user* with *new_user* in the disk group. All files that are currently owned by *old_user* will become owned by *new_user*, and *old_user* will be dropped from the disk group. *old_user* must exist in the disk group and *new_user* must not exist in the disk group.

file_permissions_clause

Use this clause to change the permission settings of a disk group file. The three classes of permissions are owner, user group, and other. You must be the file owner or the Oracle ASM administrator to use this clause.

If you change the permission settings of an open file, then the operation currently running on the file will complete using the old permission settings. The new permission settings will take effect when re-authentication is required.

file_owner_clause

Use this clause to set the owner or user group for a specified file. You must be the Oracle ASM administrator to change the owner of the file. You must be the owner of the file or the Oracle ASM administrator to change the user group of a file. In addition, to change the associated user group of a file, the specified user group must already exist in the disk group, and the owner of the file must be a member of that user group.

If you use this clause on an open file, then the following conditions apply:

- If you change the owner or user group of an open file, then the operation currently running on the file will complete using the old owner or user group. The new owner or user group will take effect when re-authentication is required.
- If you change the owner of an open file, then the new owner of the file cannot be dropped from the disk group until the instance has been restarted. In an Oracle ASM cluster, the new owner of the file cannot be dropped until all instances in the cluster have been restarted.
- If you change the owner of an open file, then the old owner cannot be dropped while the file is still open, even after the ownership of the file has changed.

scrub_clause

Use this clause to scrub a disk group. The scrub operation checks for logical data corruptions and repairs the corruptions automatically in normal and high redundancy disks groups.

- Use the `FILE` clause to scrub the specified Oracle ASM file in the disk group. You must use one of the reference forms of the *`ASM_filename`*. Refer to *ASM_filename* for information on the reference forms of Oracle ASM filenames.
- Use the `DISK` clause to scrub the specified disk in the disk group.
- If you do not specify `FILE` or `DISK`, then all files and disks in the disk group are scrubbed.

REPAIR | NOREPAIR

Specify `REPAIR` to attempt to repair any errors found during the logical data corruption check. Specify `NOREPAIR` to be alerted of any corruptions; Oracle ASM will not take any action to resolve them. The default is `NOREPAIR`.

POWER

Use the `POWER` clause to specify the power level of the scrub operation. Valid values are `AUTO`, `LOW`, `HIGH`, and `MAX`. If you omit this clause, then the power level defaults to `AUTO` and the power adjusts to the optimum level for the system.

WAIT | NOWAIT

Specify `WAIT` to allow the scrub operation to complete before returning control to the user. Specify `NOWAIT` to add the operation to the scrubbing queue and return control to the user immediately. The default is `NOWAIT`.

FORCE | NOFORCE

Specify `FORCE` to process the command even if the system I/O load is high or scrubbing has been disabled at the system level. Specify `NOFORCE` to process the command normally. The default is `NOFORCE`.

STOP

Specify `STOP` if you want to stop an ongoing scrub operation.

You can monitor the progress of the scrub operation by querying the `V$ASM_ OPERATION` dynamic performance view.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for more information on scrubbing disk groups and "Scrubbing a Disk Group: Example"

quotagroup_clauses

Use these clauses to add a quota group to the disk group, modify a quota group, move a file group into a quota group, or drop a quota group.

A quota group is a collection of file groups. A file group is a container for all files of a database within one disk group. A quota group has a specified quota limit, which is the maximum amount of storage space that its file groups can collectively use. Therefore, a quota group enables you

to define the quota limit for a group of databases within a disk group. The sum of the quota limits for all quota groups in a disk group can exceed the storage capacity of the disk group.

Each disk group contains a default quota group named `GENERIC`. If you create a file group and do not specify its quota group, then the file group belongs to the `GENERIC` quota group. Oracle ASM automatically creates the `GENERIC` quota group when you create a disk group with the `compatible.asm` attribute set to `12.2` or higher, or when you set `compatible.asm` to `12.2` or higher for an existing disk group. Initially, the quota limit for `GENERIC` is `UNLIMITED`. You can subsequently modify this quota limit with the `MODIFY QUOTAGROUP` clause.

ADD QUOTAGROUP

Use this clause to create a quota group and add it to the disk group. For *`quotagroup_name`*, specify the name of the new quota group.

The `SET` clause allows you to set the quota limit for the quota group.

- For *`property_name`*, specify `QUOTA`.
- For *`property_value`*, specify one of the following clauses:
  - Specify *`size_clause`* to set a number of bytes for the quota limit. The minimum value you can specify is 1 byte. You can specify a value that is greater than the storage size of the disk group. In this case, storage use is limited by the current size of the disk group. However, if you subsequently increase the storage space for the disk group to a size that exceeds the quota limit, then the quota limit will be enforced. Refer to *size_clause* for the syntax and semantics of this clause. Note that specifying 0 bytes is equivalent to specifying `UNLIMITED`.
  - Specify `UNLIMITED` if you do not want to set a quota limit. In this case, storage use is limited by the storage size of the disk group.

If you omit the `SET` clause, then the default is `SET QUOTA=UNLIMITED`.

MODIFY QUOTAGROUP

Use this clause to modify the quota limit for a quota group. For *`quotagroup_name`*, specify the name of the quota group you want to modify. You can modify the quota limit for any quota group, including the `GENERIC` quota group. The `SET` clause has the same semantics here as for the `ADD QUOTAGROUP` clause. The quota limit can be set below the amount of space currently used by the quota group. This action prevents any additional space from being allocated for files described by file groups associated with this quota group.

MOVE FILEGROUP

Use this clause to move a file group from one quota group to another. For *`filegroup_name`*, specify the file group you want to move. For *`quotagroup_name`*, specify the name of the destination quota group. If the move operation causes the amount of used storage space in the destination quota group to exceed the quota limit, then the operation succeeds, but no new storage allocations can take place in the file groups within the quota group. This capability enables you to stop any files described by a specific file group from allocating additional space.

DROP QUOTAGROUP

Use this clause to drop a quota group from the disk group. For *`quotagroup_name`*, specify the quota group you want to drop. The quota group must not contain any file groups. You cannot drop the quota group `GENERIC`.

> **See Also:**
>
> *Automatic Storage Management Administrator's Guide* for more information on quota groups

filegroup_clauses

The *filegroup_clauses* are valid only for flex disk groups. Use these clauses to create a file group, modify a file group, move a file into a file group, or drop a file group. A file group is a container for all files of a database within one disk group. A file group must belong to a quota group.

Each disk group has a default file group with FILEGROUP_NUMBER = 0.

add_filegroup_clause

Use this clause to create a file group.

For *filegroup_name*, specify the name of the new file group. The maximum length of a file group name is 127 characters. The name must satisfy the requirements listed in "Database Object Naming Rules ", with the following addition: File group names are not case sensitive, even if you specify them with quotation marks. They are always stored internally as uppercase. File group names must be unique within a disk group.

- Use the DATABASE clause to specify the database (non-CDB, CDB, or PDB) with which the file group is associated.
- Use the CLUSTER clause to specify the cluster with which the file group is associated.
- Use the VOLUME clause to specify the volume with which the file group is associated.
- Use the TEMPLATE clause to create a file group template with which the file group is associated. You can use the template to customize a set of file group properties, that can then be inherited by one or more databases.

You cannot associate more than one file group in the same disk group with the same database, cluster, volume, or template. If the database, cluster, volume, or template does not exist at the time of file group creation, then the file group will be automatically associated with it when it is subsequently created. Database, cluster, volume, and template names must satisfy the requirements listed in "Database Object Naming Rules ".

The SET clause allows you to set properties for the file group. If you do not specify the SET clause for a property, then the default value is assigned. You can specify the *file_type* for any property for which a file type applies. If you do not specify *file_type* for such a property, then the property applies to all file types. For complete information on file group properties and their default values, see *Oracle Automatic Storage Management Administrator's Guide*.

Example 1: Create a file group from a file group template to inherit properties from the template

```
ALTER DISKGROUP hmdg ADD FILEGROUP fgtem TEMPLATE SET 'datafile.redundancy'='unprotected'
    ALTER DISKGROUP hmdg ADD FILEGROUP fgdb DATABASE NONE FROM TEMPLATE fgtem
```

Example 2: Create a file group or a tablespace from a file group template to inherit properties from the template

```
ALTER DISKGROUP hmdg ADD FILEGROUP fgtem2 TEMPLATE
    CREATE TABLESPACE tbs1 datafile '+hmdg(fg$fgtem2)/dbs/tbs1.f' size 1M
```

modify_filegroup_clause

Use this clause to modify file group properties. For *filegroup_name*, specify the name of the file group you want to modify. You can modify properties for any file group, including the default file group. Any that you do not specify with this clause remain unchanged. The SET clause has the same semantics here as for the *add_filegroup_clause*.

move_to_filegroup_clause

Use this clause to move a file to a file group. If the file is currently associated with a different file group, then it is disassociated from that file group. The target file group must have enough space available to contain the file. You must be the owner of the file and the target file group.

drop_filegroup_clause

Use this clause to drop an empty file group. For *filegroup_name*, specify the name of the file group you want to drop.

CASCADE

Use the keyword CASCADE to drop a file group that is not empty. When a file group is dropped with the keyword CASCADE, every file associated with the file group is automatically dropped.

FOR DATABASE Clause

- If the file group being dropped is associated with a pluggable database, then the FOR PLUGGABLE DATABASE clause names the pluggable database in *pdb_name*. You must then specify the FOR DATABASE clause with *db_unique_name*, the name of the container database that contains the pluggable database.
- If the file group being dropped is associated with a non-CDB database, then the FOR DATABASE clause names the non-CDB database in *db_unique_name*.
- You can specify the CASCADE clause with FOR PLUGGABLE DATABASE and FOR DATABASE.

  Use the CASCADE option to delete every file associated with the file group as part of the file group drop.

  When a file group of type DATABASE is dropped using the CASCADE option, ASM checks the OMF (Oracle Managed File) file name of the files being deleted to verify that they belong to the database or pluggable database that is associated with the file group being dropped.

> **See Also:**
>
> *Automatic Storage Management Administrator's Guide* for more information on file groups

undrop_disk_clause

Use this clause to cancel the drop of disks from the disk group. You can cancel the pending drop of all the disks in one or more disk groups (by specifying *diskgroup_name*) or of all the disks in all disk groups (by specifying ALL).

This clause is not relevant for disks that have already been completely dropped from the disk group or for disk groups that have been completely dropped. This clause results in a long-

running operation. You can see the status of the operation by querying the V$ASM_OPERATION dynamic performance view.

> **See Also:**
>
> V$ASM_OPERATION for more information on the details of long-running Oracle ASM operations

diskgroup_availability

Use this clause to make one or more disk groups available or unavailable to the database instances running on the same node as the Oracle ASM instance. This clause does not affect the status of the disk group on other nodes in a cluster.

MOUNT

Specify MOUNT to mount the disk groups in the local Oracle ASM instance. Specify ALL MOUNT to mount all disk groups specified in the ASM_DISKGROUPS initialization parameter. File operations can only be performed when a disk group is mounted. If Oracle ASM is running in a cluster or a standalone server managed by Oracle Grid Infrastructure for a standalone server, then the MOUNT clause automatically brings the corresponding resource online.

RESTRICTED | NORMAL

Use these clauses to determine the manner in which the disk groups are mounted.

- In the RESTRICTED mode, the disk group is mounted in single-instance exclusive mode. No other Oracle ASM instance in the same cluster can mount that disk group. In this mode the disk group is not usable by any Oracle ASM client.
- In the NORMAL mode, the disk group is mounted in shared mode, so that other Oracle ASM instances and clients can access the disk group. This is the default.

FORCE | NOFORCE

Use these clauses to determine the circumstances under which the disk groups are mounted.

- In the FORCE mode, Oracle ASM attempts to mount the disk group even if it cannot discover all of the devices that belong to the disk group. This setting is useful if some of the disks in a normal or high redundancy disk group became unavailable while the disk group was dismounted. When MOUNT FORCE succeeds, Oracle ASM takes the missing disks offline.

  If Oracle ASM discovers *all* of the disks in the disk group, then MOUNT FORCE fails. Therefore, use the MOUNT FORCE setting only if some disks are unavailable. Otherwise, use NOFORCE.

  In normal- and high-redundancy disk groups, disks from one failure group can be unavailable and MOUNT FORCE will succeed. Also in high-redundancy disk groups, two disks in two different failure groups can be unavailable and MOUNT FORCE will succeed. Any other combination of unavailable disks causes the operation to fail, because Oracle ASM cannot guarantee that a valid copy of all user data or metadata exists on the available disks.
- In the NOFORCE mode, Oracle ASM does not attempt to mount the disk group unless it can discover all the member disks. This is the default.

> **See Also:**
>
> `ASM_DISKGROUPS` for more information about adding disk group names to the initialization parameter file

DISMOUNT

Specify `DISMOUNT` to dismount the specified disk groups. Oracle ASM returns an error if any file in the disk group is open unless you also specify `FORCE`. Specify `ALL DISMOUNT` to dismount all currently mounted disk groups. File operations can only be performed when a disk group is mounted. If Oracle ASM is running in a cluster or a standalone server managed by Oracle Grid Infrastructure for a standalone server, then the `DISMOUNT` clause automatically takes the corresponding resource offline.

FORCE

Specify `FORCE` if you want Oracle ASM to dismount the disk groups even if some files in the disk group are open.

enable_disable_volume

Use this clause to enable or disable one or more volumes in the disk group.

- For each volume you enable, Oracle ASM creates a volume device file on the local node that can be used to create or mount the file system.
- For each volume you disable, Oracle ASM deletes the device file on the local node. If the volume file is open on the local node, then the `DISABLE` clause returns an error.

Use the `ALL` keyword to enable or disable all volumes in the disk group. If you specify `ALTER DISKGROUP ALL ...`, then you must use the `ALL` keyword in this clause as well.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for more information about disk group volumes

Examples

The following examples require a disk group called `dgroup_01`. They assume that `ASM_DISKSTRING` is set to `/devices/disks/*`. In addition, they assume the Oracle user has read/write permission to `/devices/disks/d100`. Refer to "Creating a Diskgroup: Example" to create `dgroup_01`.

Adding a Disk to a Disk Group: Example

To add a disk, `d100`, to a disk group, `dgroup_01`, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  ADD DISK '/devices/disks/d100';
```

Dropping a Disk from a Disk Group: Example

To drop a disk, `dgroup_01_0000`, from a disk group, `dgroup_01`, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  DROP DISK dgroup_01_0000;
```

Undropping a Disk from a Disk Group: Example

To cancel the drop of disks from a disk group, `dgroup_01`, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  UNDROP DISKS;
```

Resizing a Disk Group: Example

To resize every disk in a disk group, `dgroup_01`, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  RESIZE ALL
  SIZE 36G;
```

Rebalancing a Disk Group: Example

To manually rebalance a disk group, `dgroup_01`, and permit Oracle ASM to execute the rebalance as fast as possible, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  REBALANCE POWER 11 WAIT;
```

The `WAIT` keyword causes the database to wait for the disk group to be rebalanced before returning control to the user.

Verifying the Internal Consistency of Disk Group Metadata: Example

To verify the internal consistency of Oracle ASM disk group metadata and instruct Oracle ASM to repair any errors found, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  CHECK ALL
  REPAIR;
```

Adding a Named Template to a Disk Group: Example

To add a named template, `template_01` to a disk group, `dgroup_01`, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  ADD TEMPLATE template_01
    ATTRIBUTES (UNPROTECTED COARSE);
```

Changing the Attributes of a Disk Group Template: Example

To modify the attributes of a system default or user-defined disk group template, `template_01`, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  MODIFY TEMPLATE template_01
    ATTRIBUTES (FINE);
```

Dropping a User-Defined Template from a Disk Group: Example

To drop a user-defined template, `template_01`, from a disk group, `dgroup_01`, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  DROP TEMPLATE template_01;
```

Creating a Directory Path for Hierarchically Named Aliases: Example

To specify the directory structure in which alias names will reside, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  ADD DIRECTORY '+dgroup_01/alias_dir';
```

Creating an Alias Name for an Oracle ASM Filename: Example

To create a user alias by specifying the numeric Oracle ASM filename, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  ADD ALIAS '+dgroup_01/alias_dir/datafile.dbf'
    FOR '+dgroup_01.261.1';
```

Scrubbing a Disk Group: Example

To scrub a disk group, `dgroup_01`, issue the following statement. This statement attempts to repair any errors found during the logical data corruption check and allows the scrub operation to complete before returning control to the user.

```
ALTER DISKGROUP dgroup_01
  SCRUB REPAIR WAIT;
```

Dismounting a Disk Group: Example

To dismount a disk group, `dgroup_01`, issue the following statement. This statement dismounts the disk group even if one or more files are active:

```
ALTER DISKGROUP dgroup_01
  DISMOUNT FORCE;
```

Mounting a Disk Group: Example

To mount a disk group, `dgroup_01`, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  MOUNT;
```

ALTER DOMAIN

Purpose

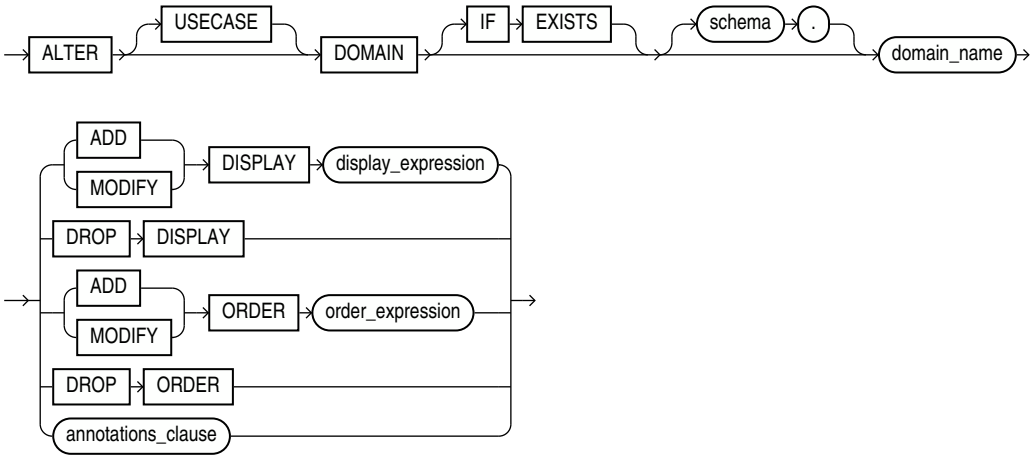
Use this statement to make changes to a domain. When you alter a domain note that checks and catalog changes are made on objects dependent on the domain.

Prerequisites

The domain must be in your own schema, or you must have `ALTER` object privilege on the domain, or you must have `ALTER ANY DOMAIN` system privilege.

Syntax

***alter_domain* ::=**



annotations_clause

For the full syntax and semantics of the `annotations_clause` see *annotations_clause*.

Semantics

USECASE

This keyword is optional and is provided for semantic clarity. It indicates that the domain is to describe a data use case.

IF EXISTS

Specify `IF EXISTS` to alter an existing domain.

Specifying `IF NOT EXISTS` with `ALTER DOMAIN` results in the error: `Incorrect IF EXISTS clause for ALTER/DROP statement`.

ADD DISPLAY

Adds the `display_expression` to the domain. Raises an error if the domain already has a `display_expression` .

Invalidates all SQL statements referencing `DOMAIN_DISPLAY` for an expression of the given domain.

For domain functions see Domain Functions

MODIFY DISPLAY

Changes the domain's display expression to *`display_expression`* and invalidates all SQL statements referencing `DOMAIN_DISPLAY` for an expression of the given domain.

Raises an error if the domain does not have an associated display expression

Invalidates all SQL statements referencing `DOMAIN_DISPLAY` for an expression of the given domain.

Both `ALTER DOMAIN ADD DISPLAY` and `ALTER DOMAIN MODIFY DISPLAY` type-check the display expression against all the allowed data types of the domain.

DROP DISPLAY

Raises an error if the domain does not have a display expression. Raises an error If the domain has dependent flexible domain.

Otherwise it removes the display expression from the domain's description, and invalidates all SQL statements referencing `DOMAIN_DISPLAY` for an expression of the given domain.

ADD MODIFY DROP ORDER

The semantics of these DDLs are the same as for `DISPLAY`, when translated to the `ORDER` expression and `DOMAIN_ORDER` function.

annotations_clause

> **See Also:**
>
> - For the full semantics of the annotations clause see *annotations_clause*.
> - CREATE DOMAIN

Examples

The following statement changes the display expression of the domain `day_of_week`. It raises an error if the domain does not have a display expression:

```
ALTER DOMAIN day_of_week
      MODIFY DISPLAY LOWER(day_of_week);
```

The following statement removes the display expression from the domain `day_of_week`. It raises an error if the domain does not have a display expression:

```
ALTER DOMAIN day_of_week
      DROP DISPLAY;
```

The following statement an display expression to the domain `day_of_week`. It raises an error if the domain already has a display expression:

```
ALTER DOMAIN day_of_week
      ADD DISPLAY INITCAP(day_of_week);
```

The following statement changes the order expression of the domain `year_of_birth`. It raises an error if the domain does not have an order expression:

```
ALTER DOMAIN year_of_birth
      MODIFY ORDER MOD(year_of_birth,100);
```

The following statement removes the order expression from the domain `year_of_birth`. It raises an error if the domain does not have an order expression:

```
ALTER DOMAIN year_of_birth
      DROP ORDER;
```

The following statement an order expression to the domain `year_of_birth`. It raises an error if the domain already has an order expression:

```
ALTER DOMAIN year_of_birth
      ADD ORDER FLOOR(year_of_birth/100);
```

The following example adds the annotation `Display` with the value "`day_of_week`" to the domain. If the domain already has the `Display` annotation it raises an error:

```
ALTER DOMAIN day_of_week
      ANNOTATIONS(Display 'Day of week');
```

ALTER FLASHBACK ARCHIVE

Purpose

Use the `ALTER FLASHBACK ARCHIVE` statement for these operations:

- Designate a flashback archive as the default flashback archive for the system
- Add a tablespace for use by the flashback archive
- Change the quota of a tablespace used by the flashback archive
- Remove a tablespace from use by the flashback archive
- Change the retention period of the flashback archive
- Purge the flashback archive of old data that is no longer needed

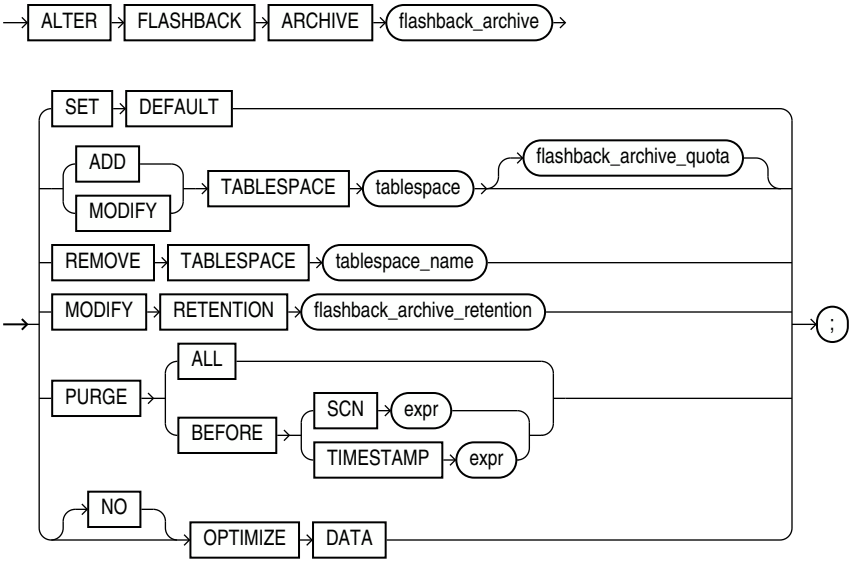
> **See Also:**
>
> *Oracle Database Development Guide* and CREATE FLASHBACK ARCHIVE for more information on using Flashback Time Travel

Prerequisites

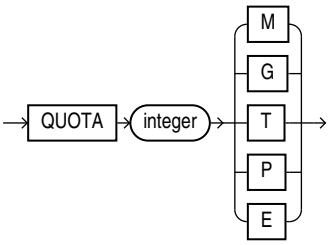
You must have the `FLASHBACK ARCHIVE ADMINISTER` system privilege to alter a flashback archive in any way. You must also have appropriate privileges on the affected tablespaces to add, modify, or remove a flashback archive tablespace.

Syntax

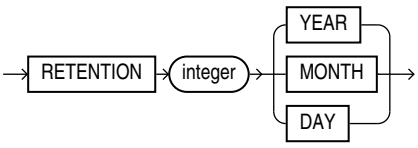
***alter_flashback_archive*::=**



***flashback_archive_quota*::=**



***flashback_archive_retention*::=**



Semantics

flashback_archive

Specify the name of an existing flashback archive.

SET DEFAULT

You must be logged in as `SYSDBA` to specify this clause. Use this clause to designate this flashback archive as the default flashback archive for the system. When a `CREATE TABLE` or

`ALTER TABLE` statement specifies the *`flashback_archive_clause`* without specifying a flashback archive name, the database uses the default flashback archive to store data from that table.

This statement overrides any previous designation of a different flashback archive as the default.

> **See Also:**
>
> The `CREATE TABLE` *flashback_archive_clause* for more information

ADD TABLESPACE

Use this clause to add a tablespace to the flashback archive. You can use the *`flashback_archive_quota`* clause to specify the amount of space that can be used by the flashback archive in the new tablespace. If you omit that clause, then the flashback archive has unlimited space in the newly added tablespace.

MODIFY TABLESPACE

Use this clause to change the tablespace quota of a tablespace already used by the flashback archive.

REMOVE TABLESPACE

Use this clause to remove a tablespace from use by the flashback archive. You cannot remove the last remaining tablespace used by the flashback archive.

If the tablespace to be removed contains any data within the retention period of the flashback archive, then that data will be dropped as well. Therefore, you should move your data to another tablespace before removing the tablespace with this clause.

MODIFY RETENTION

Use this clause to change the retention period of the flashback archive.

PURGE

Use this clause to purge data from the flashback archive.

- Specify `PURGE ALL` to remove all data from the flashback archive. This historical information can be retrieved using a flashback query only if the SCN or timestamp specified in the flashback query is within the undo retention duration.
- Specify `PURGE BEFORE SCN` to remove all data from the flashback archive before the specified system change number.
- Specify `PURGE BEFORE TIMESTAMP` to remove all data from the flashback archive before the specified timestamp.

[NO] OPTIMIZE DATA

This clause has the same semantics as the [NO] OPTIMIZE DATA clause of `CREATE FLASHBACK ARCHIVE`.

> **See Also:**
>
> CREATE FLASHBACK ARCHIVE for information on creating flashback archives and for some simple examples of using flashback archives

ALTER FUNCTION

Purpose

Functions are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `ALTER FUNCTION` statement to recompile an invalid standalone stored function. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

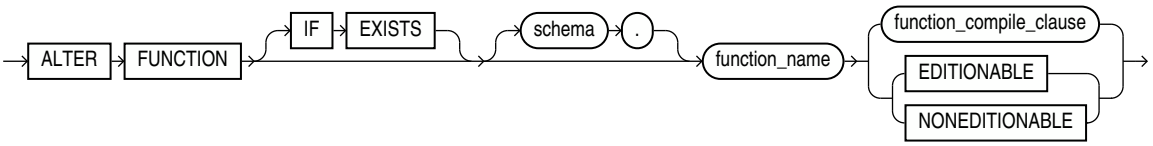
This statement does not change the declaration or definition of an existing function. To redeclare or redefine a function, use the `CREATE FUNCTION` statement with the `OR REPLACE` clause. See CREATE FUNCTION .

Prerequisites

The function must be in your own schema or you must have `ALTER ANY PROCEDURE` system privilege.

Syntax

***alter_function*::=**



(*function_compile_clause*: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

schema

Specify the schema containing the function. If you omit *schema*, then Oracle Database assumes the function is in your own schema.

function_name

Specify the name of the function to be recompiled.

function_compile_clause

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling functions.

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the function becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `FUNCTION` in *`schema`*. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

ALTER HIERARCHY

Purpose

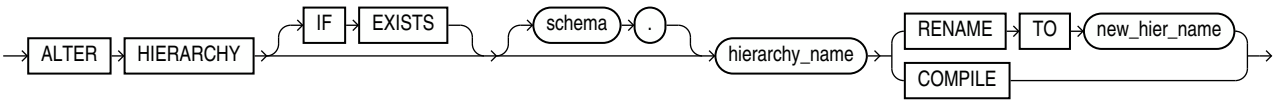
Use the `ALTER HIERARCHY` statement to rename or compile a hierarchy. For other alterations, use `CREATE OR REPLACE HIERARCHY`.

Prerequisites

To alter a hierarchy in your own schema, you must have the `ALTER HIERARCHY` system privilege. To alter a hierarchy in another user's schema, you must have the `ALTER ANY HIERARCHY` system privilege or have been granted `ALTER` directly on the hierarchy.

Syntax

***alter_hierarchy*::=**



Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

schema

Specify the schema in which the hierarchy exists. If you do not specify a schema, then Oracle Database looks for the hierarchy in your own schema.

hierarchy_name

Specify the name of the hierarchy.

RENAME TO

Specify `RENAME TO` to change the name of the hierarchy.

COMPILE

Specify `COMPILE` to compile the hierarchy.

new_hier_name

Specify a new name for the hierarchy.

Example

The following statement changes the name of a hierarchy:

```
ALTER HIERARCHY product_hier RENAME TO myproduct_hier;
```

ALTER INDEX

Purpose

Use the `ALTER INDEX` statement to change or rebuild an existing index.

> **See Also:**
>
> CREATE INDEX for information on creating an index

Prerequisites

The index must be in your own schema or you must have the `ALTER ANY INDEX` system privilege.

To execute the `MONITORING USAGE` clause, the index must be in your own schema.

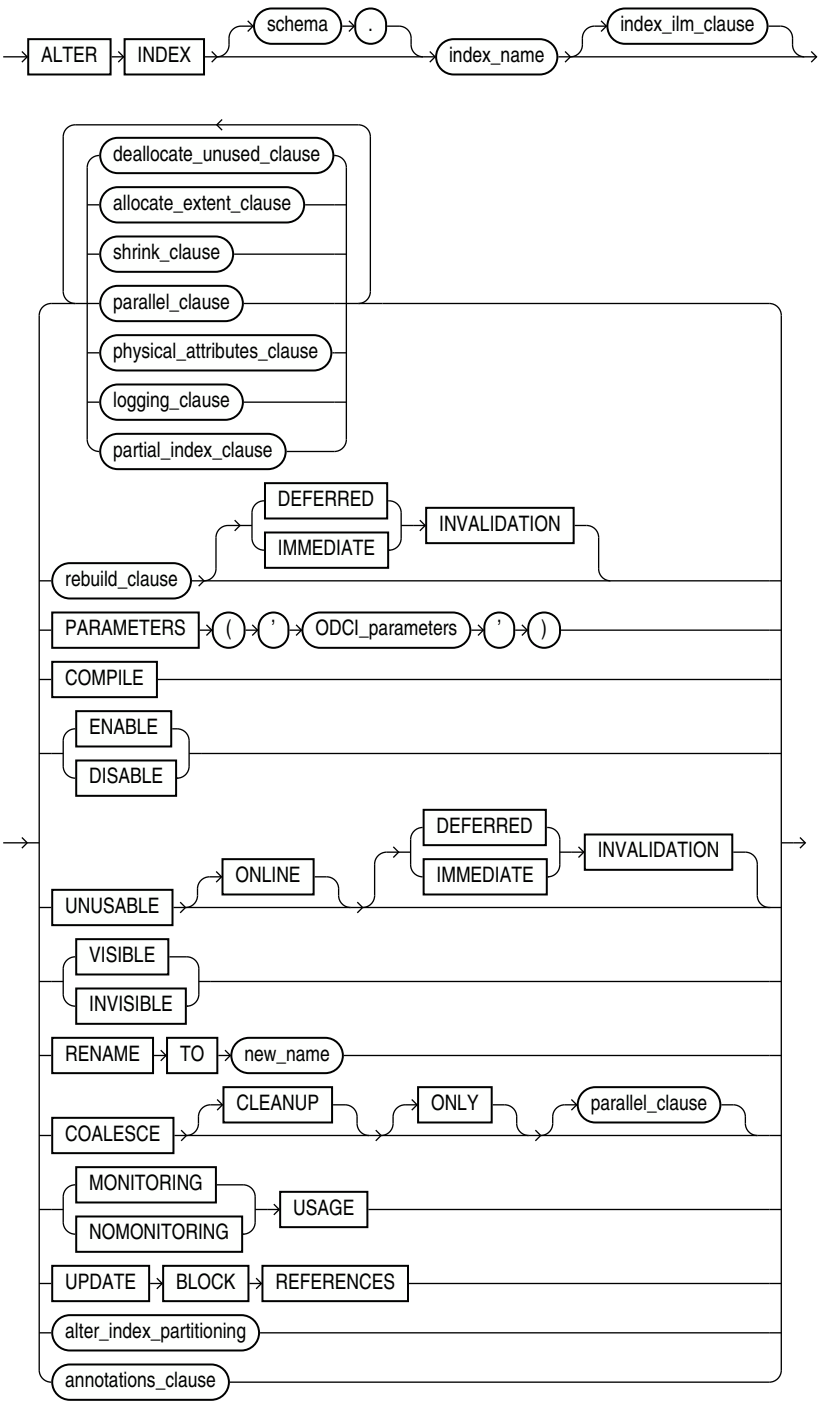
To modify a domain index, you must have `EXECUTE` object privilege on the indextype of the index.

Object privileges are granted on the parent index, not on individual index partitions or subpartitions.

You must have tablespace quota to modify, rebuild, or split an index partition or to modify or rebuild an index subpartition.

Syntax

***alter_index*::=**



(*deallocate_unused_clause*::=, *allocate_extent_clause*::=, *shrink_clause*::=, *parallel_clause*::=, *physical_attributes_clause*::=, *logging_clause*::=, *partial_index_clause*::=, *rebuild_clause*::=, *alter_index_partitioning*::=)

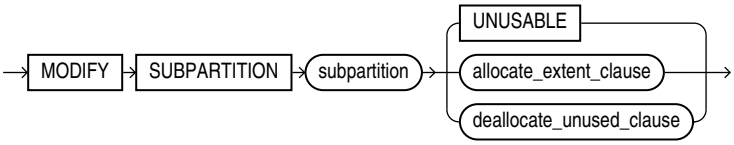
***modify_index_subpartition*::=**



(*allocate_extent_clause*::=, *deallocate_unused_clause*::=)

Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing index.

Specifying `IF NOT EXISTS` with `ALTER INDEX` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

schema

Specify the schema containing the index. If you omit *schema*, then Oracle Database assumes the index is in your own schema.

index_name

Specify the name of the index to be altered.

Restrictions on Modifying Indexes

The modification of indexes is subject to the following restrictions:

- If *index* is a domain index, then you can specify only the `PARAMETERS` clause, the `RENAME` clause, the *rebuild_clause* (with or without the `PARAMETERS` clause), the *parallel_clause*, or the `UNUSABLE` clause. No other clauses are valid.
- You cannot alter or rename a domain index that is marked `LOADING` or `FAILED`. If an index is marked `FAILED`, then the only clause you can specify is `REBUILD`.

> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide* for information on the `LOADING` and `FAILED` states of domain indexes

index_ilm_clause

Please refer to *index_ilm_clause* in `CREATE INDEX` for full semantics.

deallocate_unused_clause

Use the *deallocate_unused_clause* to explicitly deallocate unused space at the end of the index and make the freed space available for other segments in the tablespace.

If *index* is range-partitioned or hash-partitioned, then Oracle Database deallocates unused space from each index partition. If *index* is a local index on a composite-partitioned table, then Oracle Database deallocates unused space from each index subpartition.

Restrictions on Deallocating Space

Deallocation of space is subject to the following restrictions:

- You cannot specify this clause for an index on a temporary table.
- You cannot specify this clause and also specify the *rebuild_clause*.

Refer to *deallocate_unused_clause* for a full description of this clause.

KEEP *integer*

The `KEEP` clause lets you specify the number of bytes above the high water mark that the index will have after deallocation. If the number of remaining extents is less than `MINEXTENTS`, then `MINEXTENTS` is set to the current number of extents. If the initial extent becomes smaller than `INITIAL`, then `INITIAL` is set to the value of the current initial extent. If you omit `KEEP`, then all unused space is freed.

Refer to ALTER TABLE for a complete description of this clause.

allocate_extent_clause

The *`allocate_extent_clause`* lets you explicitly allocate a new extent for the index. For a local index on a hash-partitioned table, Oracle Database allocates a new extent for each partition of the index.

Restriction on Allocating Extents

You cannot specify this clause for an index on a temporary table or for a range-partitioned or composite-partitioned index.

Refer to *allocate_extent_clause* for a full description of this clause.

shrink_clause

Use this clause to compact the index segments. Specifying `ALTER INDEX ... SHRINK SPACE COMPACT` is equivalent to specifying `ALTER INDEX ... COALESCE`.

For complete information on this clause, refer to *shrink_clause* in the documentation on `CREATE TABLE`.

Restriction on Shrinking Index Segments

You cannot specify this clause for a bitmap join index or for a function-based index.

parallel_clause

Use the `PARALLEL` clause to change the default degree of parallelism for queries and DML on the index.

Restriction on Parallelizing Indexes

You cannot specify this clause for an index on a temporary table.

For complete information on this clause, refer to *parallel_clause* in the documentation on `CREATE TABLE`.

> **See Also:**
>
> "Enabling Parallel Queries: Example"

physical_attributes_clause

Use the *`physical_attributes_clause`* to change the values of parameters for a nonpartitioned index, all partitions and subpartitions of a partitioned index, a specified partition, or all subpartitions of a specified partition.

> **See Also:**
>
> - the physical attributes parameters in CREATE TABLE
> - "Modifying Real Index Attributes: Example" and "Changing MAXEXTENTS: Example"

Restrictions on Index Physical Attributes

Index physical attributes are subject to the following restrictions:

- You cannot specify this clause for an index on a temporary table.
- You cannot specify the `PCTUSED` parameter at all when altering an index.
- You can specify the `PCTFREE` parameter only as part of the *`rebuild_clause`*, the *`modify_index_default_attrs`* clause, or the *`split_index_partition`* clause.

storage_clause

Use the *`storage_clause`* to change the storage parameters for a nonpartitioned index, index partition, or all partitions of a partitioned index, or default values of these parameters for a partitioned index. Refer to storage_clause for complete information on this clause.

logging_clause

Use the *`logging_clause`* to change the logging attribute of the index. If you also specify the `REBUILD` clause, then this new setting affects the rebuild operation. If you specify a different value for logging in the `REBUILD` clause, then Oracle Database uses the last logging value specified as the logging attribute of the index and of the rebuild operation.

An index segment can have logging attributes different from those of the base table and different from those of other index segments for the same base table.

Restriction on Index Logging

You cannot specify this clause for an index on a temporary table.

> **See Also:**
>
> - *logging_clause* for a full description of this clause
> - *Oracle Database VLDB and Partitioning Guide* for more information about parallel DML

partial_index_clause

Use the *`partial_index_clause`* to change the index to a full index or a partial index. Specify `INDEXING FULL` to change the index to a full index. Specify `INDEXING PARTIAL` to change the index to a partial index. This clause is valid only for indexes on partitioned tables. Refer to the *partial_index_clause* of `CREATE INDEX` for the full semantics of this clause.

RECOVERABLE | UNRECOVERABLE

These keywords are deprecated and have been replaced with `LOGGING` and `NOLOGGING`, respectively. Although `RECOVERABLE` and `UNRECOVERABLE` are supported for backward compatibility, Oracle strongly recommends that you use the `LOGGING` and `NOLOGGING` keywords.

`RECOVERABLE` is not a valid keyword for creating partitioned tables or LOB storage characteristics. `UNRECOVERABLE` is not a valid keyword for creating partitioned or index-organized tables. Also, it can be specified only with the `AS` subquery clause of `CREATE INDEX`.

rebuild_clause

Use the *rebuild_clause* to re-create an existing index or one of its partitions or subpartitions. If index is marked `UNUSABLE`, then a successful rebuild will mark it `USABLE`. For a function-based index, this clause also enables the index. If the function on which the index is based does not exist, then the rebuild statement will fail.

> **Note:**
>
> When you rebuild the secondary index of an index-organized table, Oracle Database preserves the primary key columns contained in the logical rowid when the index was created. Therefore, if the index was created with the `COMPATIBLE` initialization parameter set to less than 10.0.0, the rebuilt index will contain the index key and any of the primary key columns of the table that are not also in the index key. If the index was created with the `COMPATIBLE` initialization parameter set to 10.0.0 or greater, then the rebuilt index will contain the index key and all the primary key columns of the table, including those also in the index key.

Restrictions on Rebuilding Indexes

The rebuilding of indexes is subject to the following restrictions:

- You cannot rebuild an index on a temporary table.
- You cannot rebuild a bitmap index that is marked `INVALID`. Instead, you must drop and then re-create it.
- You cannot rebuild an entire partitioned index. You must rebuild each partition or subpartition, as described for the `PARTITION` clause.
- You cannot specify the *deallocate_unused_clause* in the same statement as the *rebuild_clause*.
- You cannot change the value of the `PCTFREE` parameter for the index as a whole (`ALTER INDEX`) or for a partition (`ALTER INDEX ... MODIFY PARTITION`). You can specify `PCTFREE` in all other forms of the `ALTER INDEX` statement.
- For a domain index:
  - You can specify only the `PARAMETERS` clause (either for the index or for a partition of the index) or the *parallel_clause*. No other rebuild clauses are valid.
  - You can rebuild an index only if the index is not marked `IN_PROGRESS`.
  - You can rebuild an index partition only if the index is not marked `IN_PROGRESS` or `FAILED` and the partition is not marked `IN_PROGRESS`.

- You cannot rebuild a local index, but you can rebuild a partition of a local index (`ALTER INDEX ... REBUILD PARTITION`).
- For a local index on a hash partition or subpartition, the only parameter you can specify is `TABLESPACE`.
- You cannot rebuild an online index that is used to enforce a deferrable unique constraint.

PARTITION Clause

Use the `PARTITION` clause to rebuild one partition of an index. You can also use this clause to move an index partition to another tablespace or to change a create-time physical attribute.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to *Oracle Database VLDB and Partitioning Guide* for a discussion of these restrictions.

Restriction on Rebuilding Partitions

You cannot specify this clause for a local index on a composite-partitioned table. Instead, use the `REBUILD SUBPARTITION` clause.

> **See Also:**
>
> *Oracle Database VLDB and Partitioning Guide* for more information about partition maintenance operations and "Rebuilding Unusable Index Partitions: Example"

SUBPARTITION Clause

Use the `SUBPARTITION` clause to rebuild one subpartition of an index. You can also use this clause to move an index subpartition to another tablespace. If you do not specify `TABLESPACE`, then the subpartition is rebuilt in the same tablespace.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to *Oracle Database VLDB and Partitioning Guide* for a discussion of these restrictions.

Restriction on Modifying Index Subpartitions

The only parameters you can specify for a subpartition are `TABLESPACE`, `ONLINE`, and the *`parallel_clause`*.

REVERSE | NOREVERSE

Indicate whether the bytes of the index block are stored in reverse order:

- `REVERSE` stores the bytes of the index block in reverse order and excludes the rowid when the index is rebuilt.
- `NOREVERSE` stores the bytes of the index block without reversing the order when the index is rebuilt. Rebuilding a `REVERSE` index without the `NOREVERSE` keyword produces a rebuilt, reverse-keyed index.

Restrictions on Reverse Indexes

Reverse indexes are subject to the following restrictions:

- You cannot reverse a bitmap index or an index-organized table.

- You cannot specify `REVERSE` or `NOREVERSE` for a partition or subpartition.

> **See Also:**
>
> "Storing Index Blocks in Reverse Order: Example"

parallel_clause

Use the *parallel_clause* to parallelize the rebuilding of the index and to change the degree of parallelism for the index itself. All subsequent operations on the index will be executed with the degree of parallelism specified by this clause, unless overridden by a subsequent data definition language (DDL) statement with the *parallel_clause*. The following exceptions apply:

- If `ALTER SESSION DISABLE PARALLEL DDL` was specified before rebuilding the index, then the index will be rebuilt serially and the degree of parallelism for the index will be changed to 1.
- If `ALTER SESSION FORCE PARALLEL DDL` was specified before rebuilding the index, then the index will be rebuilt in parallel and the degree of parallelism for the index will be changed to the value that was specified in the `ALTER SESSION` statement, or `DEFAULT` if no value was specified.

> **See Also:**
>
> "Rebuilding an Index in Parallel: Example"

TABLESPACE Clause

Specify the tablespace where the rebuilt index, index partition, or index subpartition will be stored. The default is the default tablespace where the index or partition resided before you rebuilt it.

index_compression

Use the *index_compression* clauses to enable or disable index compression for the index. Specify the *prefix_compression* clause to enable or disable prefix compression for the index. Specify the *advanced_index_compression* clause to enable or disable advanced index compression for the index.

The *index_compression* clauses have the same semantics for `CREATE INDEX` and `ALTER INDEX`. For full information on these clauses, refer to *index_compression* in the documentation on `CREATE INDEX`.

ONLINE Clause

Specify `ONLINE` to allow DML operations on the table or partition during rebuilding of the index.

Restrictions on Online Indexes

Online indexes are subject to the following restrictions:

- Parallel DML is not supported during online index building. If you specify `ONLINE` and subsequently issue parallel DML statements, then Oracle Database returns an error.

- You cannot specify `ONLINE` for a bitmap join index or a cluster index.
- For a nonunique secondary index on an index-organized table, the number of index key columns plus the number of primary key columns that are included in the logical rowid in the index-organized table cannot exceed 32. The logical rowid excludes columns that are part of the index key.

logging_clause

Specify whether the `ALTER INDEX ... REBUILD` operation will be logged.

Refer to the *logging_clause* for a full description of this clause.

PARAMETERS Clause

This clause is valid only for domain indexes in a top-level `ALTER INDEX` statement and in the *`rebuild_clause`*. This clause specifies the parameter string that is passed uninterpreted to the appropriate ODCI indextype routine.

The maximum length of the parameter string is 1000 characters.

If you are altering or rebuilding an entire index, then the string must refer to index-level parameters. If you are rebuilding a partition of the index, then the string must refer to partition-level parameters.

If *`index`* is marked `UNUSABLE`, then modifying the parameters alone does not make it `USABLE`. You must also rebuild the `UNUSABLE` index to make it usable.

If you have installed Oracle Text, then you can rebuild your Oracle Text domain indexes using parameters specific to that product. For more information on those parameters, refer to *Oracle Text Reference*.

Restriction on the PARAMETERS Clause

You can modify index partitions only if *`index`* is not marked `IN_PROGRESS` or `FAILED`, no index partitions are marked `IN_PROGRESS`, and the partition being modified is not marked `FAILED`.

> **See Also:**
>
> - *Oracle Database Data Cartridge Developer's Guide* for more information on indextype routines for domain indexes
> - CREATE INDEX for more information on domain indexes

XMLIndex_parameters_clause

This clause is valid only for XMLIndex indexes. This clause specifies the parameter string that defines the XMLIndex implementation.

The maximum length of the parameter string is 1000 characters.

If you are altering or rebuilding an entire index, then the string must refer to index-level parameters. If you are rebuilding a partition of the index, then the string must refer to partition-level parameters.

If *`index`* is marked `UNUSABLE`, then modifying the parameters alone does not make it `USABLE`. You must also rebuild the `UNUSABLE` index to make it usable.

> **See Also:**
>
> *Oracle XML DB Developer's Guide* for more information on `XMLIndex`, including the syntax and semantics of the *`XMLIndex_parameters_clause`*

Restriction on the *XMLIndex_parameters_clause*

You can modify index partitions only if *`index`* is not marked `IN_PROGRESS` or `FAILED`, no index partitions are marked `IN_PROGRESS`, and the partition being modified is not marked `FAILED`.

{ DEFERRED | IMMEDIATE } INVALIDATION

This clause lets you control when the database invalidates dependent cursors while rebuilding an index or while marking an index `UNUSABLE`.

- If you specify `DEFERRED INVALIDATION`, then the database avoids or defers invalidating dependent cursors, when possible.
- If you specify `IMMEDIATE INVALIDATION`, then the database immediately invalidates dependent cursors, as it did in Oracle Database 12*c* Release 1 (12.1) and prior releases. This is the default.

If you omit this clause, then the value of the `CURSOR_INVALIDATION` initialization parameter determines when cursors are invalidated.

> **See Also:**
>
> - *Oracle Database SQL Tuning Guide* for more information on cursor invalidation
> - *Oracle Database Reference* for more information in the `CURSOR_INVALIDATION` initialization parameter

COMPILE Clause

Use this clause to recompile an invalid index explicitly. For domain indexes, this clause is useful when the underlying indextype has been altered to support system-managed domain indexes, so that the existing domain index has been marked `INVALID`. In this situation, this `ALTER INDEX` statement migrates the domain index from a user-managed domain index to a system-managed domain index. For all types of indexes, this clause is useful when an index has been marked `INVALID` by an `ALTER TABLE` statement. In this situation, this `ALTER INDEX` statement revalidates the index without rebuilding it.

> **See Also:**
>
> The `CREATE INDEXTYPE` *storage_table_clause* and *Oracle Database Data Cartridge Developer's Guide* for information on creating system-managed domain indexes

ENABLE Clause

ENABLE applies only to a function-based index that has been disabled, either by an ALTER INDEX ... DISABLE statement, or because a user-defined function used by the index was dropped or replaced. This clause enables such an index if these conditions are true:

- The function is currently valid.
- The signature of the current function matches the signature of the function when the index was created.
- The function is currently marked as DETERMINISTIC.

Restrictions on Enabling Function-based Indexes

The ENABLE clause is subject to the following restrictions:

- You cannot specify any other clauses of ALTER INDEX in the same statement with ENABLE.
- You cannot specify this clause for an index on a temporary table. Instead, you must drop and recreate the index. You can retrieve the creation DDL for the index using the DBMS_METADATA package.

DISABLE Clause

DISABLE applies only to a function-based index. This clause lets you disable the use of a function-based index. You might want to do so, for example, while working on the body of the function. Afterward you can either rebuild the index or specify another ALTER INDEX statement with the ENABLE keyword.

USABLE | UNUSABLE

Specify UNUSABLE to mark the index or index partition(s) or index subpartition(s) UNUSABLE. The space allocated for an index or index partition or subpartition is freed immediately when the object is marked UNUSABLE. An unusable index must be rebuilt, or dropped and re-created, before it can be used. While one partition is marked UNUSABLE, the other partitions of the index are still valid. You can execute statements that require the index if the statements do not access the unusable partition. You can also split or rename the unusable partition before rebuilding it. Refer to CREATE INDEX ... USABLE | UNUSABLE for more information.

ONLINE

Specify ONLINE to indicate that DML operations on the table or partition will be allowed while marking the index UNUSABLE. If you specify this clause, then the database will not drop the index segments.

Restrictions on Marking Indexes Unusable

The following restrictions apply to marking indexes unusable:

- You cannot specify UNUSABLE for an index on a temporary table.
- When a global index is marked UNUSABLE during a partition maintenance operation, the database does not drop the unusable index segments.

VISIBLE | INVISIBLE

Use this clause to specify whether the index is visible or invisible to the optimizer. Refer to "VISIBLE | INVISIBLE" in CREATE INDEX for a full description of this clause.

RENAME Clause

Use this clause to rename an index. The *new_index_name* is a single identifier and does not include the schema name.

Restriction on Renaming Indexes

For a domain index, neither *index* nor any partitions of *index* should be in `IN_PROGRESS` or `FAILED` state.

> **See Also:**
>
> - *Building Domain Indexes* of the *Data Cartridge Developer's Guide*.
> - *Extensible Indexing Interface* of the *Data Cartridge Developer's Guide*.
> - Renaming an Index: Example

COALESCE Clause

Specify `COALESCE` to instruct Oracle Database to merge the contents of index blocks where possible to free blocks for reuse.

CLEANUP

Specify `CLEANUP` to remove orphaned index entries for records that were previously dropped or truncated by a table partition maintenance operation.

To determine whether an index contains orphaned index entries, you can query the `ORPHANED_ENTRIES` column of the `USER_`, `DBA_`, `ALL_INDEXES` data dictionary views. Refer to *Oracle Database Reference* for more information.

ONLY

Specify `ONLY` when you want to clean up the index without coalescing the index blocks.

parallel_clause

Use the *parallel_clause* to specify whether to parallelize the coalesce operation.

For complete information on this clause, refer to *parallel_clause* in the documentation on `CREATE TABLE`.

Restrictions on Coalescing Index Blocks

Coalescing of index blocks is subject to the following restrictions:

- You cannot specify this clause for an index on a temporary table.
- Do not specify this clause for the primary key index of an index-organized table. Instead use the `COALESCE` clause of `ALTER TABLE`.

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for more information on space management and coalescing indexes
> - COALESCE Clause for information on coalescing the space of an index-organized table
> - *shrink_clause* for an alternative method of compacting index segments

MONITORING USAGE | NOMONITORING USAGE

Use this clause to determine whether Oracle Database should monitor index use.

- Specify `MONITORING USAGE` to begin monitoring the index. Oracle Database first clears existing information on index use, and then monitors the index for use until a subsequent `ALTER INDEX ... NOMONITORING USAGE` statement is executed.
- To terminate monitoring of the index, specify `NOMONITORING USAGE`.

To see whether the index has been used since this `ALTER INDEX ... NOMONITORING USAGE` statement was issued, query the `USED` column of the `USER_OBJECT_USAGE` data dictionary view.

> **See Also:**
>
> *Oracle Database Reference* for information on the `USER_OBJECT_USAGE` data dictionary view

UPDATE BLOCK REFERENCES Clause

The `UPDATE BLOCK REFERENCES` clause is valid only for normal and domain indexes on index-organized tables. Specify this clause to update all the stale guess data block addresses stored as part of the index row with the correct database address for the corresponding block identified by the primary key.

For a domain index, Oracle Database executes the `ODCIIndexAlter` routine with the `alter_option` parameter set to `AlterIndexUpdBlockRefs`. This routine enables the cartridge code to update the stale guess data block addresses in the index.

Restriction on UPDATE BLOCK REFERENCES

You cannot combine this clause with any other clause of `ALTER INDEX`.

annotations_clause

For the full semantics of the annotations clause see *annotations_clause*.

alter_index_partitioning

The partitioning clauses of the `ALTER INDEX` statement are valid only for partitioned indexes.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to *Oracle Database VLDB and Partitioning Guide* for a discussion of these restrictions.

Restrictions on Modifying Index Partitions

Modifying index partitions is subject to the following restrictions:

- You cannot specify any of these clauses for an index on a temporary table.
- You can combine several operations on the base index into one `ALTER INDEX` statement (except `RENAME` and `REBUILD`), but you cannot combine partition operations with other partition operations or with operations on the base index.

modify_index_default_attrs

Specify new values for the default attributes of a partitioned index.

Restriction on Modifying Partition Default Attributes

The only attribute you can specify for a hash-partitioned global index or for an index on a hash-partitioned table is `TABLESPACE`.

TABLESPACE

Specify the default tablespace for new partitions of an index or subpartitions of an index partition.

logging_clause

Specify the default logging attribute of a partitioned index or an index partition.

Refer to *logging_clause* for a full description of this clause.

FOR PARTITION

Use the `FOR PARTITION` clause to specify the default attributes for the subpartitions of a partition of a local index on a composite-partitioned table.

Restriction on FOR PARTITION

You cannot specify `FOR PARTITION` for a list partition.

> **See Also:**
>
> "Modifying Default Attributes: Example"

add_hash_index_partition

Use this clause to add a partition to a global hash-partitioned index. Oracle Database adds hash partitions and populates them with index entries rehashed from an existing hash partition of the index, as determined by the hash function. If you omit the partition name, then Oracle Database assigns a name of the form `SYS_Pn`. If you omit the `TABLESPACE` clause, then Oracle Database places the partition in the tablespace specified for the index. If no tablespace is specified for the index, then Oracle Database places the partition in the default tablespace of the user, if one has been specified, or in the system default tablespace.

modify_index_partition

Use the *modify_index_partition* clause to modify the real physical attributes, logging attribute, or storage characteristics of index partition *partition* or its subpartitions. For a hash-partitioned global index, the only subclause of this clause you can specify is `UNUSABLE`.

COALESCE

Specify this clause to merge the contents of index partition blocks where possible to free blocks for reuse.

CLEANUP

Specify `CLEANUP` to remove orphaned index entries for records that were previously dropped or truncated by a table partition maintenance operation.

To determine whether an index partition contains orphaned index entries, you can query the `ORPHANED_ENTRIES` column of the `USER_`, `DBA_`, `ALL_PART_INDEXES` data dictionary views. Refer to *Oracle Database Reference* for more information.

UPDATE BLOCK REFERENCES

The `UPDATE BLOCK REFERENCES` clause is valid only for normal indexes on index-organized tables. Use this clause to update all stale guess data block addresses stored in the secondary index partition.

Restrictions on UPDATE BLOCK REFERENCES

This clause is subject to the following restrictions:

- You cannot specify the *`physical_attributes_clause`* for an index on a hash-partitioned table.
- You cannot specify `UPDATE BLOCK REFERENCES` with any other clause in `ALTER INDEX`.

> **Note:**
>
> If the index is a local index on a composite-partitioned table, then the changes you specify here will override any attributes specified earlier for the subpartitions of index, as well as establish default values of attributes for future subpartitions of that partition. To change the default attributes of the partition without overriding the attributes of subpartitions, use `ALTER TABLE ... MODIFY DEFAULT ATTRIBUTES FOR PARTITION`.

> **See Also:**
>
> "Marking an Index Unusable: Examples"

UNUSABLE Clause

This clause has the same function for index partitions that it has for the index as a whole. Refer to "USABLE | UNUSABLE".

index_compression

This clause is relevant for composite-partitioned indexes. Use this clause to change the compression attribute for the partition and every subpartition in that partition. Oracle Database marks each index subpartition in the partition `UNUSABLE` and you must then rebuild these subpartitions. Prefix compression must already have been specified for the index before you can specify the *`prefix_compression`* clause for a partition, or advanced index compression must have already been specified for the index before you can specify the

advanced_index_compression clause for a partition. You can specify this clause only at the partition level. You cannot change the compression attribute for an individual subpartition.

You can use this clause for noncomposite index partitions. However, it is more efficient to use the *rebuild_clause* for noncomposite partitions, which lets you rebuild and set the compression attribute in one step.

rename_index_partition

Use the *rename_index_partition* clauses to rename index *partition* or *subpartition* to *new_name*.

Restrictions on Renaming Index Partitions

Renaming index partitions is subject to the following restrictions:

- You cannot rename the subpartition of a list partition.
- For a partition of a domain index, *index* cannot be marked `IN_PROGRESS` or `FAILED`, none of the partitions can be marked `IN_PROGRESS`, and the partition you are renaming cannot be marked `FAILED`.

> **See Also:**
>
> "Renaming an Index Partition: Example"

drop_index_partition

Use the *drop_index_partition* clause to remove a partition and the data in it from a partitioned global index. When you drop a partition of a global index, Oracle Database marks the next index partition `UNUSABLE`. You cannot drop the highest partition of a global index.

> **See Also:**
>
> "Dropping an Index Partition: Example"

split_index_partition

Use the *split_index_partition* clause to split a partition of a global range-partitioned index into two partitions, adding a new partition to the index. This clause is not valid for hash-partitioned global indexes. Instead, use the *add_hash_index_partition* clause.

Splitting a partition marked `UNUSABLE` results in two partitions, both marked `UNUSABLE`. You must rebuild the partitions before you can use them.

Splitting a partition marked `USABLE` results in two partitions populated with index data. Both new partitions are marked `USABLE`.

AT Clause

Specify the new noninclusive upper bound for *split_partition_1*. The *value_list* must evaluate to less than the presplit partition bound for *partition_name_old* and greater than the partition bound for the next lowest partition (if there is one).

INTO Clause

Specify (optionally) the name and physical attributes of each of the two partitions resulting from the split.

> **See Also:**
>
> "Splitting a Partition: Example"

coalesce_index_partition

This clause is valid only for hash-partitioned global indexes. Oracle Database reduces by one the number of index partitions. Oracle Database selects the partition to coalesce based on the requirements of the hash function. Use this clause if you want to distribute index entries of a selected partition into one of the remaining partitions and then remove the selected partition.

modify_index_subpartition

Use the *modify_index_subpartition* clause to mark `UNUSABLE` or allocate or deallocate storage for a subpartition of a local index on a composite-partitioned table. All other attributes of such a subpartition are inherited from partition-level default attributes.

Examples

Storing Index Blocks in Reverse Order: Example

The following statement rebuilds index `ord_customer_ix` (created in "Creating an Index: Example") so that the bytes of the index block are stored in reverse order:

```
ALTER INDEX ord_customer_ix REBUILD REVERSE;
```

Rebuilding an Index in Parallel: Example

The following statement causes the index to be rebuilt from the existing index by using parallel execution processes to scan the old and to build the new index:

```
ALTER INDEX ord_customer_ix REBUILD PARALLEL;
```

Modifying Real Index Attributes: Example

The following statement alters the `oe.cust_lname_ix` index so that future data blocks within this index use 5 initial transaction entries:

```
ALTER INDEX oe.cust_lname_ix
    INITRANS 5;
```

If the `oe.cust_lname_ix` index were partitioned, then this statement would also alter the default attributes of future partitions of the index. Partitions added in the future would then use 5 initial transaction entries and an incremental extent of 100K.

Enabling Parallel Queries: Example

The following statement sets the parallel attributes for index `upper_ix` (created in "Creating a Function-Based Index: Example") so that scans on the index will be parallelized:

```
ALTER INDEX upper_ix PARALLEL;
```

Renaming an Index: Example

The following statement renames an index:

```
ALTER INDEX upper_ix RENAME TO upper_name_ix;
```

Marking an Index Unusable: Examples

The following statements use the `cost_ix` index, which was created in "Creating a Range-Partitioned Global Index: Example". Partition `p1` of that index was dropped in "Dropping an Index Partition: Example". The first statement marks index partition `p2` as `UNUSABLE`:

```
ALTER INDEX cost_ix
   MODIFY PARTITION p2 UNUSABLE;
```

The next statement marks the entire index `cost_ix` as `UNUSABLE`:

```
ALTER INDEX cost_ix UNUSABLE;
```

Rebuilding Unusable Index Partitions: Example

The following statements rebuild partitions `p2` and `p3` of the `cost_ix` index, making the index once more usable: The rebuilding of partition `p3` will not be logged:

```
ALTER INDEX cost_ix
   REBUILD PARTITION p2;
ALTER INDEX cost_ix
   REBUILD PARTITION p3 NOLOGGING;
```

Changing MAXEXTENTS: Example

The following statement changes the maximum number of extents for partition `p3` and changes the logging attribute:

```
/* This example will fail if the tablespace in which partition p3
   resides is locally managed.
*/
ALTER INDEX cost_ix MODIFY PARTITION p3
   STORAGE(MAXEXTENTS 30) LOGGING;
```

Renaming an Index Partition: Example

The following statement renames an index partition of the `cost_ix` index (created in "Creating a Range-Partitioned Global Index: Example"):

```
ALTER INDEX cost_ix
   RENAME PARTITION p3 TO p3_Q3;
```

Splitting a Partition: Example

The following statement splits partition `p2` of index `cost_ix` (created in "Creating a Range-Partitioned Global Index: Example") into `p2a` and `p2b`:

```
ALTER INDEX cost_ix
   SPLIT PARTITION p2 AT (1500)
   INTO ( PARTITION p2a TABLESPACE tbs_01 LOGGING,
          PARTITION p2b TABLESPACE tbs_02);
```

Dropping an Index Partition: Example

The following statement drops index partition `p1` from the `cost_ix` index:

```
ALTER INDEX cost_ix
   DROP PARTITION p1;
```

Modifying Default Attributes: Example

The following statement alters the default attributes of local partitioned index `prod_idx`, which was created in "Creating an Index on a Hash-Partitioned Table: Example". Partitions added in the future will use 5 initial transaction entries:

```
ALTER INDEX prod_idx
      MODIFY DEFAULT ATTRIBUTES INITRANS 5;
```

ALTER INDEXTYPE

Purpose

Use the `ALTER INDEXTYPE` statement to add or drop an operator of the indextype or to modify the implementation type or change the properties of the indextype.

Prerequisites

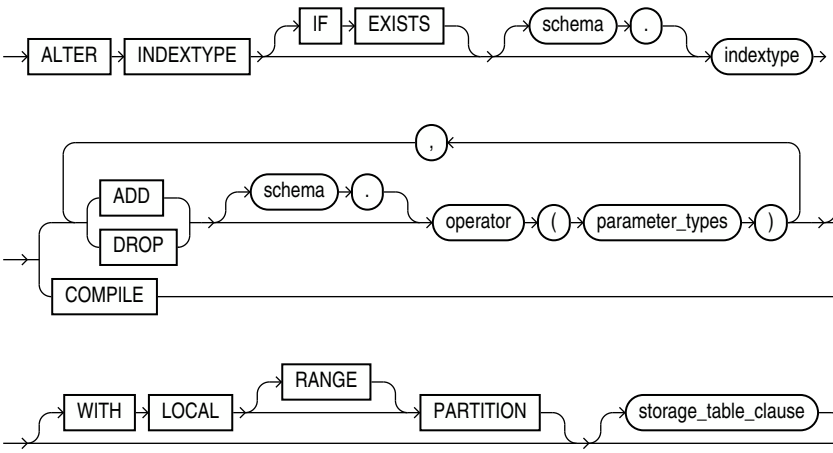
The indextype must be in your own schema or you must have the `ALTER ANY INDEXTYPE` system privilege.

To add a new operator, you must have the `EXECUTE` object privilege on the operator.

To change the implementation type, you must have the `EXECUTE` object privilege on the new implementation type.

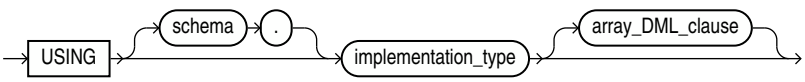
Syntax

***alter_indextype*::=**



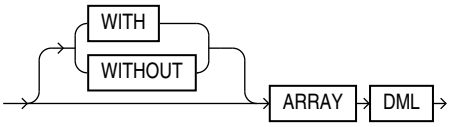
(*using_type_clause*::=, *storage_table_clause*)

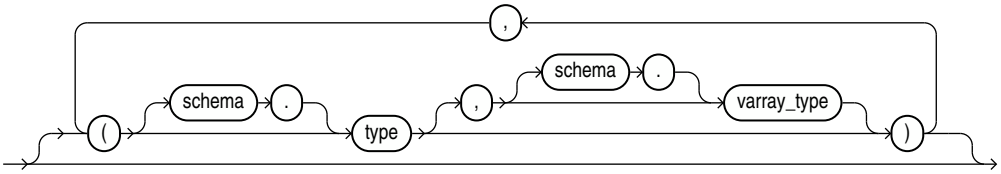
***using_type_clause*::=**



(*array_DML_clause*)

array_DML_clause





storage_table_clause

Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

schema

Specify the name of the schema in which the indextype resides. If you omit *`schema`*, then Oracle Database assumes the indextype is in your own schema.

indextype

Specify the name of the indextype to be modified.

ADD | DROP

Use the `ADD` or `DROP` clause to add or drop an operator.

No special privilege needed to drop.

- For *`schema`*, specify the schema containing the operator. If you omit *`schema`*, then Oracle assumes the operator is in your own schema.
- For *`operator`*, specify the name of the operator supported by the indextype.

  All the operators listed in this clause must be valid operators.
- For *`parameter_type`*, list the types of parameters to the operator.

using_type_clause

The `USING` clause lets you specify a new type to provide the implementation for the indextype.

array_DML_clause

Use this clause to modify the indextype to support the array interface for the `ODCIIndexInsert` method.

type* and *varray_type

If the data type of the column to be indexed is a user-defined object type, then you must specify this clause to identify the varray *`varray_type`* that Oracle should use to hold column values of *`type`*. If the indextype supports a list of types, then you can specify a corresponding list of varray types. If you omit *`schema`* for either *`type`* or *`varray_type`*, then Oracle assumes the type is in your own schema.

If the data type of the column to be indexed is a built-in system type, then any varray type specified for the indextype takes precedence over the ODCI types defined by the system.

COMPILE

Use this clause to recompile the indextype explicitly. This clause is required only after some upgrade operations, because Oracle Database normally recompiles the indextype automatically.

storage_table_clause

This clause has the same behavior when altering an indextype that it has when you are creating an indextype. Refer to the `CREATE INDEXTYPE` *storage_table_clause* for more information.

WITH LOCAL PARTITION

This clause has the same behavior when altering an indextype that it has when you create an indextype. Refer to the `CREATE INDEXTYPE` clause WITH LOCAL PARTITION for more information.

Examples

Altering an Indextype: Example

The following example compiles the `position_indextype` indextype created in "Creating an Indextype: Example".

```
ALTER INDEXTYPE position_indextype COMPILE;
```

ALTER INMEMORY JOIN GROUP

Purpose

Use the `ALTER INMEMORY JOIN GROUP` statement to add a table column to a join group or remove a table column from a join group.

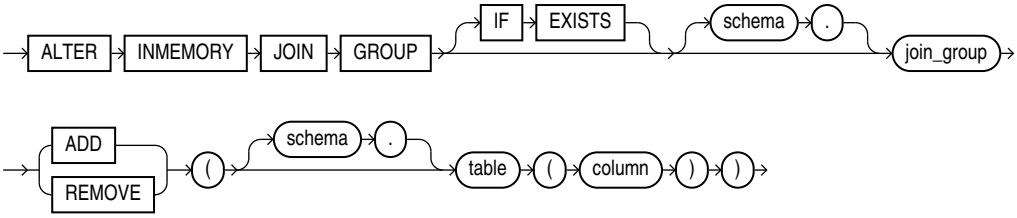
> **See Also:**
>
> - CREATE INMEMORY JOIN GROUP and DROP INMEMORY JOIN GROUP
> - *Oracle Database In-Memory Guide* for more information on join groups

Prerequisites

If the join group is not in your own schema, or if the column you want to add to or remove from the join group is in a table that is not in your own schema, then you must have the `ALTER ANY TABLE` system privilege.

Syntax

***alter_inmemory_join_group*::=**



Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

schema

Specify the schema containing the join group. If you omit *`schema`*, then the database assumes the join group is in your own schema.

join_group

Specify the name of the join group to be modified.

You can view existing join groups by querying the `DBA_JOINGROUPS` or `USER_JOINGROUPS` data dictionary view. Refer to *Oracle Database Reference* for more information on these views.

ADD

Specify `ADD` to add a table column to the join group. A join group can contain a maximum of 255 columns.

REMOVE

Specify `REMOVE` to remove a table column from the join group. A join group must contain at least 2 columns.

schema

Specify the schema of the table that contains the column to be added to or removed from the join group. If you omit *`schema`*, then Oracle Database assumes the table is in your own schema.

table

Specify the name of the table that contains the column to be added to or removed from the join group.

column

Specify the name of the column to be added to or removed from the join group.

Examples

The following example adds a column to the `prod_id1` join group created in Examples in the documentation on `CREATE INMEMORY JOIN GROUP`:

```
ALTER INMEMORY JOIN GROUP prod_id1
  ADD(product_descriptions(product_id));
```

The following example removes a column from the `prod_id1` join group:

```
ALTER INMEMORY JOIN GROUP prod_id1
  REMOVE(product_descriptions(product_id));
```

ALTER JAVA

Purpose

Use the `ALTER JAVA` statement to force the resolution of a Java class schema object or compilation of a Java source schema object. (You cannot call the methods of a Java class before all its external references to Java names are associated with other classes.)

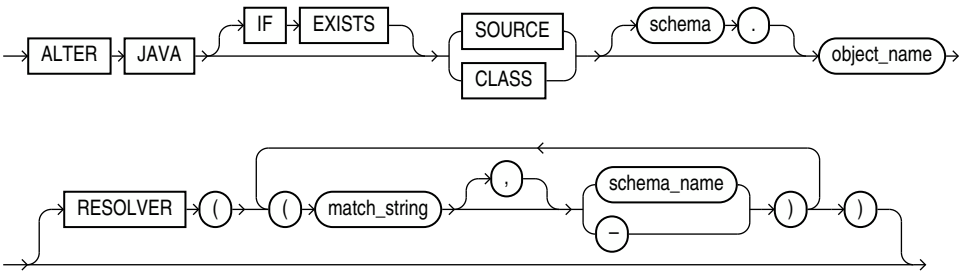
> **See Also:**
>
> *Oracle Database Java Developer's Guide* for more information on resolving Java classes and compiling Java sources

Prerequisites

The Java source or class must be in your own schema, or you must have the `ALTER ANY PROCEDURE` system privilege. You must also have the `EXECUTE` object privilege on Java classes.

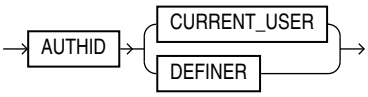
Syntax

***alter_java*::=**



(*invoker_rights_clause*::=)

***invoker_rights_clause*::=**



Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

JAVA SOURCE

Use `ALTER JAVA SOURCE` to compile a Java source schema object.

JAVA CLASS

Use `ALTER JAVA CLASS` to resolve a Java class schema object.

object_name

Specify a previously created Java class or source schema object. Use double quotation marks to preserve lower- or mixed-case names.

RESOLVER

The `RESOLVER` clause lets you specify how schemas are searched for referenced fully specified Java names, using the mapping pairs specified when the Java class or source was created.

> **See Also:**
>
> CREATE JAVA and "Resolving a Java Class: Example"

RESOLVE | COMPILE

`RESOLVE` and `COMPILE` are synonymous keywords. They let you specify that Oracle Database should attempt to resolve the primary Java class schema object.

- When applied to a class, resolution of referenced names to other class schema objects occurs.
- When applied to a source, source compilation occurs.

invoker_rights_clause

The *`invoker_rights_clause`* lets you specify whether the methods of the class execute with the privileges and in the schema of the user who defined it or with the privileges and in the schema of `CURRENT_USER`.

This clause also determines how Oracle Database resolves external names in queries, DML operations, and dynamic SQL statements in the member functions and procedures of the type.

AUTHID CURRENT_USER

Specify `CURRENT_USER` if you want the methods of the class to execute with the privileges of `CURRENT_USER`. This clause is the default and creates an **invoker-rights class**.

This clause also specifies that external names in queries, DML operations, and dynamic SQL statements resolve in the schema of `CURRENT_USER`. External names in all other statements resolve in the schema in which the methods reside.

AUTHID DEFINER

Specify `DEFINER` if you want the methods of the class to execute with the privileges of the user who defined the class.

This clause also specifies that external names resolve in the schema where the methods reside.

> **See Also:**
>
> *Oracle Database PL/SQL Language Reference* for information on how `CURRENT_USER` is determined

Examples

Resolving a Java Class: Example

The following statement forces the resolution of a Java class:

```
ALTER JAVA CLASS "Agent"
   RESOLVER (("/usr/bin/bfile_dir/*" pm)(* public))
   RESOLVE;
```

ALTER JSON RELATIONAL DUALITY VIEW

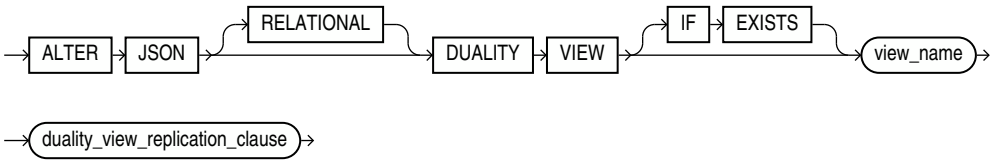
Use `ALTER JSON RELATIONAL DUALITY VIEW` to alter various options for a duality view like logical replication.

Prerequisites

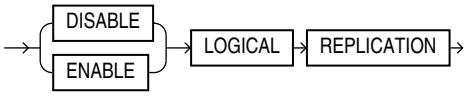
You must have one of the following privileges to use this statement:

- The view must be in your own schema
- You must have the `ALTER ANY TABLE` system privilege
- You must have the `OGG_CAPTURE` role

Syntax



duality_view_replication_clause



Semantics

duality_view_replication_clause

Steps to Enable Duality View Replication

- You can enable logical replication for the duality view using `ALTER JSON RELATIONAL DUALITY VIEW ENABLE LOGICAL REPLICATION`.

  You can also enable logical replication with the command CREATE JSON RELATIONAL DUALITY VIEW
- Minimal (or subset database replication) supplemental logging must be enabled at the database or container level using `ALTER PLUGGABLE DATABASE ADD SUPPLEMENTAL LOG DATA DDL`.
- Database *compatible* parameter must be 23.4 or higher
- Database parameter at the CDB level *enable_goldengate_replication* must be TRUE

To disable logical replication on a duality view use `ALTER JSON RELATIONAL DUALITY VIEW DISABLE LOGICAL REPLICATION`

Note:

On a multi instance RAC database, you must run the `ALTER SYSTEM ENABLE RAC TWO_STAGE ROLLING UPDATES ALL` DDL, before you can enable or disable logical replication.

After you run `ALTER SYSTEM ENABLE RAC TWO_STAGE ROLLING UPDATES ALL` you cannot perform an online downgrade (unpatch) of your RAC database to DBRU23.5 or lower. You must take a downtime.

On a single instance database, you do not need to run `ALTER SYSTEM ENABLE RAC TWO_STAGE ROLLING UPDATES ALL`.

11

SQL Statements: ALTER LIBRARY to ALTER SESSION

This chapter contains the following SQL statements:

- ALTER LIBRARY
- ALTER LOCKDOWN PROFILE
- ALTER MATERIALIZED VIEW
- ALTER MATERIALIZED VIEW LOG
- ALTER MATERIALIZED ZONEMAP
- ALTER OPERATOR
- ALTER OUTLINE
- ALTER PACKAGE
- ALTER PLUGGABLE DATABASE
- ALTER PROCEDURE
- ALTER PROFILE
- ALTER RESOURCE COST
- ALTER ROLE
- ALTER ROLLBACK SEGMENT
- ALTER SEQUENCE
- ALTER SESSION

ALTER LIBRARY

Purpose

The `ALTER LIBRARY` statement explicitly recompiles a library. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

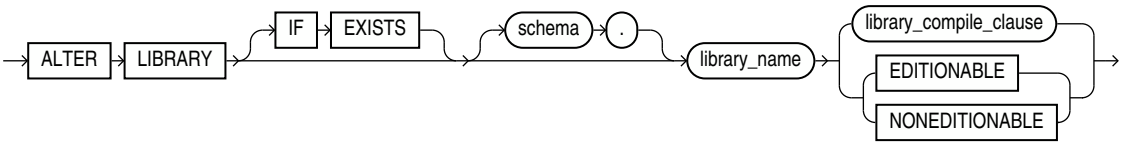
> **Note:**
>
> This statement does not change the declaration or definition of an existing library. To redeclare or redefine a library, use the "CREATE LIBRARY " with the `OR REPLACE` clause.

Prerequisites

If the library is in the `SYS` schema, you must be connected as `SYSDBA`. Otherwise, the library must be in your own schema or you must have the `ALTER ANY LIBRARY` system privilege.

Syntax

***alter_library*::=**



(*library_compile_clause*: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

schema

Specify the schema containing the library. If you omit *schema*, then Oracle Database assumes the procedure is in your own schema.

library_name

Specify the name of the library to be recompiled.

library_compile_clause

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling libraries.

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the library becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `LIBRARY` in *schema*. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

ALTER LOCKDOWN PROFILE

Purpose

Use the `ALTER LOCKDOWN PROFILE` statement to alter a PDB lockdown profile. You can use PDB lockdown profiles in a multitenant environment to restrict user operations in pluggable databases (PDBs).

Immediately after you create a lockdown profile with the `CREATE LOCKDOWN PROFILE` statement, all user operations are enabled for the profile. You can then use the `ALTER LOCKDOWN PROFILE` statement to disable certain user operations for the profile. When a lockdown profile is applied to a CDB, application container, or PDB, users cannot perform the operations that are the disabled for the profile. If you later would like to reenable some of the disabled user operations, you can use the `ALTER LOCKDOWN PROFILE` statement to do so.

The `ALTER LOCKDOWN PROFILE` statement allows you to disable or enable:

- User operations associated with certain database features (using the *`lockdown_features`* clause)
- User operations associated with certain database options (using the *`lockdown_options`* clause)
- The issuance of certain SQL statements (using the *`lockdown_statements`* clause)

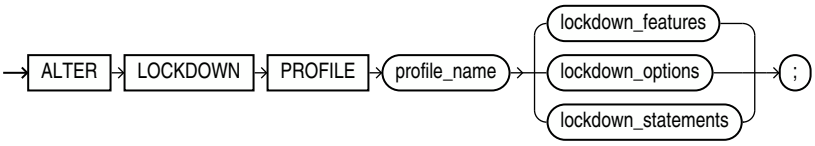
> **See Also:**
>
> - CREATE LOCKDOWN PROFILE and DROP LOCKDOWN PROFILE
> - *Oracle Database Security Guide* for more information on PDB lockdown profiles

Prerequisites

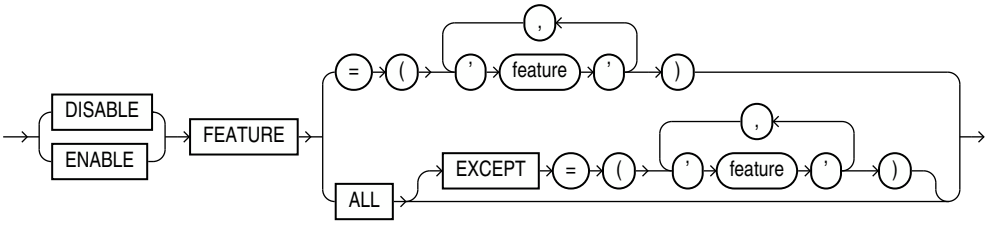
- You must issue the `ALTER LOCKDOWN PROFILE` statement from the CDB Root or Application Root.
- You must have the `ALTER LOCKDOWN PROFILE` system privilege in the container in which you issue the statement.

Syntax

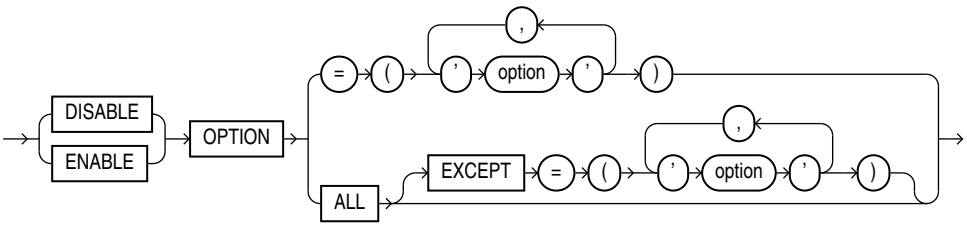
***alter_lockdown_profile*::=**



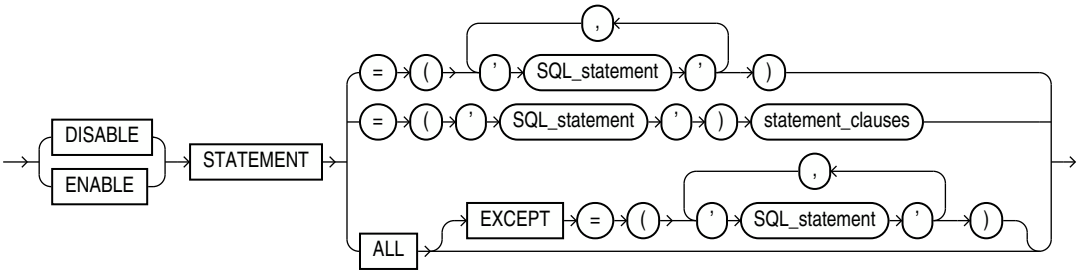
***lockdown_features*::=**



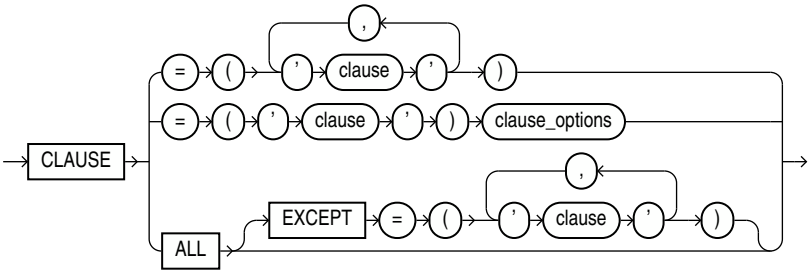
***lockdown_options*::=**



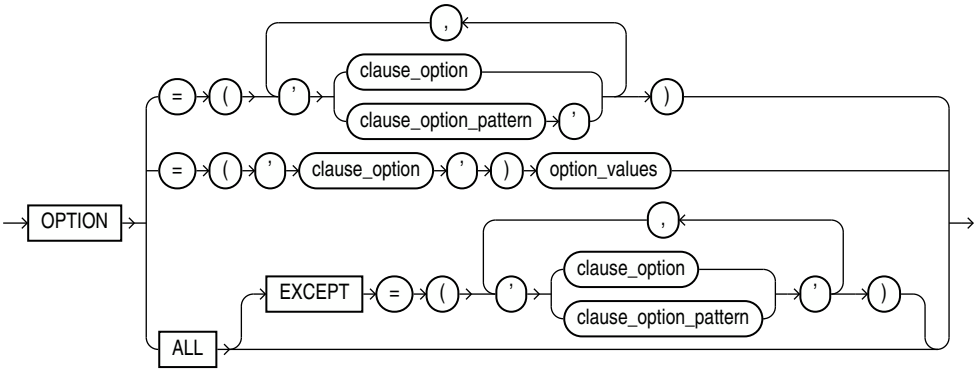
***lockdown_statements*::=**



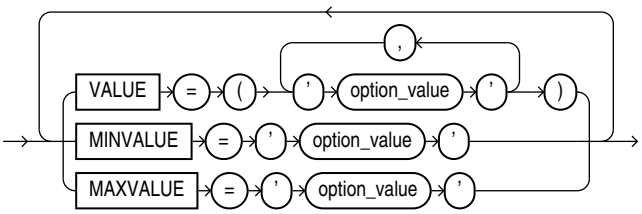
***statement_clauses*::=**



***clause_options*::=**



***option_values*::=**



Semantics

profile_name

Specify the name of the PDB lockdown profile to be altered.

You can find the names of existing PDB lockdown profiles by querying the `DBA_LOCKDOWN_PROFILES` data dictionary view.

lockdown_features

This clause lets you disable or enable user operations associated with certain database features.

- Specify `DISABLE` to add a restriction for the specified features. Users will be restricted from performing these operations in any PDB to which the profile applies.
- Specify `ENABLE` to remove a restriction for the specified features. Users will be allowed to perform these operations in any PDB to which the profile applies.
- Use *`feature`* to specify the features whose operations you want to disable or enable. Table 11-1 lists the features you can specify and describes the operations associated with each feature. The table also indicates a feature bundle for each feature. For *`feature`*, you can specify a feature bundle name to disable or enable user operations for all features in that bundle, or you can specify an individual feature name. You can specify feature bundle names and feature names in any combination of uppercase and lowercase letters.
- Use `ALL` to specify all features listed in the table.
- Use `ALL EXCEPT` to specify all features listed in the table except the specified features.

If you omit this clause, then the default is `ENABLE ALL`.

> **Note:**
>
> - The Oracle Text type `FILE_DATASTORE` is deprecated. Oracle recommends that you replace `FILE_DATASTORE` indexes with the `DIRECTORY_DATASTORE` index type for greater security as it enables file access to be based on directory objects.
> - The Oracle Text type `URL_DATASTORE` is deprecated. Oracle recommeds that you replace `URL_DATASTORE` with `NETWORK_DATASTORE`, which uses ACLs to control access to specific servers.

Table 11-1 PDB Lockdown Profile Features

Feature Bundle	Feature	Operations
AWR_ACCESS	AWR_ACCESS	The PDB taking manual and automatic Automatic Workload Repository (AWR) snapshots
COMMON_SCHEMA_ACCESS	COMMON_USER_LOCAL_SCHEMA_ACCESS	A common user invoking an invoker's rights code unit or accessing a BEQUEATH CURRENT_USER view owned by any local user in the PDB
COMMON_SCHEMA_ACCESS	LOCAL_USER_COMMON_SCHEMA_ACCESS	• A local user with an ANY system privilege (for example, CREATE ANY TABLE) creating or accessing objects in a common user's schema for which the privilege applies. **Note:** Disabling the LOCAL_USER_COMMON_SCHEMA_ACCESS feature does not prevent a local user with the SYSDBA privilege or specific object privileges from creating or accessing objects in a common user's schema. Therefore, Oracle recommends against granting such privileges to local users. • A local user with the BECOME USER system privilege becoming a common user • A local user altering a common user by issuing an ALTER USER statement • A local user using a common user for proxy connections
COMMON_SCHEMA_ACCESS	SECURITY_POLICIES	Creation of certain security policies by a local user on a common object, including: • Data Redaction • Fine Grained Auditing (FGA) • Real Application Security (RAS) • Virtual Private Database (VPD)
CONNECTIONS	COMMON_USER_CONNECT	A common user connecting to the PDB directly. If this feature is disabled, then in order to connect to the PDB, a common user must first connect to the CDB root and then switch to the desired PDB using the ALTER SESSION SET CONTAINER statement.
CONNECTIONS	LOCAL_SYSOPER_RESTRICTED_MODE_CONNECT	A local user with the SYSOPER privilege connecting to a PDB that is open in RESTRICTED mode
CTX_LOGGING	CTX_LOGGING	Use logging in Oracle Text PL/SQL procedures such as CTX_OUTPUT.START_LOG and CTX_OUTPUT.START_QUERY_LOG
JAVA	JAVA	Java as a whole. If this feature is disabled, then all options and features of the database that depend on Java will be disabled.
JAVA_RUNTIME	JAVA_RUNTIME	Operations through Java that require java.lang.RuntimePermission

Table 11-1 (Cont.) PDB Lockdown Profile Features

Feature Bundle	Feature	Operations
NETWORK_ACCESS	AQ_PROTOCOLS	Using HTTP, SMTP, and OCI notification features.
NETWORK_ACCESS	CTX_PROTOCOLS	• Operations that access the Oracle Text datastore types DIRECTORY_DATASTORE and NETWORK_DATASTORE. The type DIRECTORY_DATASTORE has an attribute called DIRECTORY which is the directory object whose data is to be indexed. The default value of this attribute is null. The DIRECTORY_DATASTORE type replaces the FILE_DATASTORE type, which is deprecated. The NETWORK_DATASTORE type replaces the URL_DATASTORE type, which is deprecated. The type NETWORK_DATASTORE conforms to the standard database security model for providing URL access based on access control lists (ACLs), which support the HTTP and HTTPS protocols. The URL_DATASTORE type did not support HTTPS. • Printing tokens as part of CTX logging with events EVENT_INDEX_PRINT_TOKEN and EVENT_OPT_PRINT_TOKEN
NETWORK_ACCESS	DBMS_DEBUG_JDWP	Using the DBMS_DEBUG_JDWP PL/SQL package
NETWORK_ACCESS	UTL_HTTP	Using the UTL_HTTP PL/SQL package
NETWORK_ACCESS	UTL_INADDR	Using the UTL_INADDR PL/SQL package
NETWORK_ACCESS	UTL_SMTP	Using the UTL_SMTP PL/SQL package
NETWORK_ACCESS	UTL_TCP	Using the UTL_TCP PL/SQL package
NETWORK_ACCESS	XDB_PROTOCOLS	Using HTTP, FTP, and other network protocols through XDB
OS_ACCESS	DROP_TABLESPACE_KEEP_DATAFILES	Dropping a tablespace in the PDB without specifying the INCLUDING CONTENTS AND DATAFILES clause in DROP TABLESPACE statement
OS_ACCESS	EXTERNAL_FILE_ACCESS	Using external files or directory objects in the PDB when PATH_PREFIX is not set for the PDB
OS_ACCESS	EXTERNAL_PROCEDURES	Using external procedure agent extproc in the PDB
OS_ACCESS	FILE_TRANSFER	Using the DBMS_FILE_TRANSFER package
OS_ACCESS	JAVA_OS_ACCESS	Using java.io.FilePermission from Java
OS_ACCESS	LOB_FILE_ACCESS	Using BFILE and CFILE data types

Table 11-1 (Cont.) PDB Lockdown Profile Features

Feature Bundle	Feature	Operations
OS_ACCESS	TRACE_VIEW_ACCESS	Using the following trace views: • [G]V$DIAG_OPT_TRACE_RECORDS • [G]V$DIAG_SQL_TRACE_RECORDS • [G]V$DIAG_TRACE_FILE_CONTENTS • V$DIAG_SESS_OPT_TRACE_RECORDS • V$DIAG_SESS_SQL_TRACE_RECORDS
OS_ACCESS	UTL_FILE	Using UTL_FILE. If this feature is disabled, then the database blocks use of the UTL_FILE.FOPEN function.

lockdown_options

This clause lets you disable or enable user operations associate with certain database options.

- Specify DISABLE to disable user operations for the specified options. Users will be restricted from performing these operations in any PDB to which the profile applies.
- Specify ENABLE to enable user operations for the specified options. Users will be allowed to perform these operations in any PDB to which the profile applies.
- For *option*, you can specify the following database options in any combination of uppercase and lowercase letters:
  - DATABASE QUEUING – Represents user operations associated with the Oracle Database Advanced Queuing option
  - PARTITIONING – Represents user operations associated with the Oracle Partitioning option
- Use ALL to specify all options in the preceding list.
- Use ALL EXCEPT to specify all options in the preceding list except the specified options.

If you omit this clause, then the default is ENABLE OPTION ALL.

lockdown_statements

This clause lets you disable or enable the issuance of certain SQL statements.

- Specify DISABLE to disable the issuance of the specified SQL statements. Users will be restricted from issuing these statements in any PDB to which the profile applies.
- Specify ENABLE to enable the issuance of the specified SQL statements. Users will be allowed to issue these statements in any PDB to which the profile applies.
- For *SQL_statement*, you can specify the following statements in any combination of uppercase and lowercase letters:
  - ADMINISTER KEY MANAGEMENT
  - ALTER DATABASE
  - ALTER PLUGGABLE DATABASE
  - ALTER SESSION
  - ALTER SYSTEM

  - ALTER TABLE
  - ALTER INDEX
  - ALTER TABLESPACE
  - ALTER PROFILE
  - CREATE TABLE
  - CREATE INDEX
  - CREATE TABLESPACE
  - CREATE PROFILE
  - CREATE DATABASE LINK
  - DROP TABLE
  - DROP INDEX
  - DROP TABLESPACE
  - DROP PROFILE
- Use ALL to specify all statements in the preceding list.
- Use ALL EXCEPT to specify all statements in the preceding list except the specified statements.

If you omit this clause, then the default is ENABLE STATEMENT ALL.

statement_clauses

This clause lets you disable or enable specific clauses of the specified SQL statement.

- Use *clause* to specify the SQL keywords that form the clause you want to disable or enable. You can specify a clause in any combination of uppercase and lowercase letters.
- Use ALL to specify all clauses for the SQL statement.
- Use ALL EXCEPT to specify all clauses for the SQL statement except the specified clauses.

For *clause*, you must specify at least enough keywords to unambiguously identify a single clause for the SQL statement. The following are some examples of how to specify *clause* for the ALTER SYSTEM statement:

- To specify the *archive_log_clause*::=, specify ARCHIVE. This is sufficient because no other ALTER SYSTEM clause begins with the keyword ARCHIVE. Alternatively, you can specify ARCHIVE LOG for semantic clarity, but the LOG keyword is unnecessary.
- To specify either of the *rolling_migration_clauses*::=, you must specify START ROLLING MIGRATION or STOP ROLLING MIGRATION in order to distinguish these clauses from the similarly named *rolling_patch_clauses*::= START ROLLING PATCH and STOP ROLLING PATCH.
- You cannot specify the single keyword FLUSH, because several ALTER SYSTEM clauses begin with this keyword. You must instead specify each clause separately, such as FLUSH SHARED_POOL or FLUSH GLOBAL CONTEXT.

There is no need to specify optional keywords within a clause, because they have no effect. For example:

- The *archive_log_clause*::= has an optional INSTANCE keyword. However, you cannot enable or disable only ARCHIVE LOG clauses that contain the INSTANCE keyword. Specifying ARCHIVE LOG INSTANCE is equivalent to specifying ARCHIVE or ARCHIVE LOG.

There is no need to specify parameter values within a clause, because they have no effect. For example:

- The *shutdown_dispatcher_clause*::= requires you to specify a *dispatcher_name*. However, you cannot enable or disable SHUTDOWN clauses that contain a specific dispatcher name. Specifying SHUTDOWN dispatcher1 is equivalent to specifying SHUTDOWN.

> **See Also:**
>
> ALTER DATABASE , ALTER PLUGGABLE DATABASE, ALTER SESSION , and ALTER SYSTEM for complete information on the clauses for these statements

clause_options

This clause is valid only when you specify one of the following for *lockdown_statements* and *statement_clauses*:

```
{ DISABLE | ENABLE } STATEMENT = ('ALTER SESSION') CLAUSE = ('SET')
{ DISABLE | ENABLE } STATEMENT = ('ALTER SYSTEM') CLAUSE = ('SET')
```

This clause lets you disable or enable the setting or modification of specific options with the ALTER SESSION SET or ALTER SYSTEM SET statements.

- Use *clause_option* to specify the option you want to disable or enable.
- Use *clause_option_pattern* to specify a pattern that matches multiple options. Within the pattern, specify a percent sign (%) to match zero or more characters in an option name. For example, specifying 'QUERY_REWRITE_%' is equivalent to specifying both the QUERY_REWRITE_ENABLED and QUERY_REWRITE_INTEGRITY options.
- You can specify *clause_option* and *clause_option_pattern* in any combination of uppercase and lowercase letters.
- Use ALL to specify all options.
- Use ALL EXCEPT to specify all options except the specified options.

> **See Also:**
>
> The *alter_session_set_clause* clause of ALTER SESSION and the *alter_system_set_clause* clause of ALTER SYSTEM for complete information on the options you can specify for these statements

option_values

This clause is valid only when you specify one of the following for *lockdown_statements*, *statement_clauses*, and *clause_options*:

```
DISABLE STATEMENT = ('ALTER SESSION') CLAUSE = ('SET') OPTION = clause_option
DISABLE STATEMENT = ('ALTER SYSTEM') CLAUSE = ('SET') OPTION = clause_option
```

This clause lets you specify a default value for an option when disabling the setting of that option. For options that take numeric values, this clause also lets you restrict users from setting an option to certain values.

- The `VALUE` clause lets you specify a default *`option_value`* for *`clause_option`*, which will go into effect for any PDB to which the profile applies after you close and reopen the PDB. If *`clause_option`* accepts multiple default values, then you can specify more than one *`option_value`* in a comma-separated list. The purpose of using this clause is to simultaneously set a default value for an option and restrict users from setting or modifying the value.
- The `MINVALUE` clause lets you restricts users from setting the value of *`clause_option`* to a value less than *`option_value`*. You can specify this clause only for options that take a numeric value.
- The `MAXVALUE` clause lets you restricts users from setting the value of *`clause_option`* to a value greater than *`option_value`*. You can specify this clause only for options that take a numeric value.
- You can specify both the `MINVALUE` and `MAXVALUE` clauses together to restrict users from setting the value of *`clause_options`* to any value less than `MINVALUE` or greater than `MAXVALUE`.
- `MINVALUE` and `MAXVALUE` settings take effect immediately when the lockdown profile is assigned to a PDB; you need not close and reopen the PDB.

> **See Also:**
>
> *Oracle Database Reference* for complete information on the values allowed for the various options

USERS Clause

As a CDB administrator or an Application administrator you can use the `USERS` clause to configure lockdown rules for a specific set of users.

The values for `USERS` in a `CDB$ROOT` lockdown profile are as follows:

- `USERS = ALL` means that the lockdown rule applies to all users in the PDB.
- `USERS = COMMON` means that the lockdown rule applies only to CDB `COMMON` users in the PDB.
- `USERS = LOCAL` means that the lockdown rule applies only to local users in the PDB. Application common users are considered local users at the CDB level.

The values for `USERS` in an Application `ROOT` lockdown profile are as follows:

- `USERS = ALL` means that the lockdown rule applies to all users in the PDB.
- `USERS = COMMON` means that the lockdown rule applies only to Application `COMMON` users in the PDB.
- `USERS = LOCAL` means that the lockdown rule applies only to local users in the PDB.

Note that the Application lockdown profile rules should not affect CDB common users.

- `ALL` users means Application common users and local users in the PDB.
- `COMMON` users means Application common users in the PDB.

Examples

The following statement creates PDB lockdown profile `hr_prof`:

```
CREATE LOCKDOWN PROFILE hr_prof;
```

The remaining examples in this section alter `hr_prof`.

Disabling Features for PDB Lockdown Profiles: Examples

The following statement disables all features in the feature bundle `NETWORK_ACCESS`:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE FEATURE = ('NETWORK_ACCESS');
```

The following statement disables the `LOB_FILE_ACCESS` and `TRACE_VIEW ACCESS` features:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE FEATURE = ('LOB_FILE_ACCESS', 'TRACE_VIEW_ACCESS');
```

The following statement disables all features except the `COMMON_USER_LOCAL_SCHEMA_ACCESS` and `LOCAL_USER_COMMON_SCHEMA_ACCESS` features:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE FEATURE ALL EXCEPT = ('COMMON_USER_LOCAL_SCHEMA_ACCESS',
'LOCAL_USER_COMMON_SCHEMA_ACCESS');
```

The following statement disables all features:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE FEATURE ALL;
```

Enabling Features for PDB Lockdown Profiles: Examples

The following statement enables the `UTL_HTTP` and `UTL_SMTP` features, as well as all features in the feature bundle `OS_ACCESS`:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE FEATURE = ('UTL_HTTP', 'UTL_SMTP', 'OS_ACCESS');
```

The following statement enables all features except the `AQ_PROTOCOLS` and `CTX_PROTOCOLS` features:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE FEATURE ALL EXCEPT = ('AQ_PROTOCOLS', 'CTX_PROTOCOLS');
```

The following statement enables all features:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE FEATURE ALL;
```

Disabling Options for PDB Lockdown Profiles: Examples

The following statement disables user operations associated with the Oracle Database Advanced Queuing option:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE OPTION = ('DATABASE QUEUING');
```

The following statement disables user operations associated with the Oracle Partitioning option:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE OPTION = ('PARTITIONING');
```

Enabling Options for PDB Lockdown Profiles: Examples

The following statement enables user operations associated with the Oracle Database Advanced Queuing option:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE OPTION = ('DATABASE QUEUING');
```

The following statement enables user operations associated both with the Oracle Database Advanced Queuing option and the Oracle Partitioning option:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE OPTION ALL;
```

Disabling SQL Statements for PBB Lockdown Profiles: Examples

The following statement disables the `ALTER DATABASE` statement:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER DATABASE');
```

The following statement disables the `ALTER SYSTEM SUSPEND` and `ALTER SYSTEM RESUME` statements:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SYSTEM')
          CLAUSE = ('SUSPEND', 'RESUME');
```

The following statement disables all clauses of the `ALTER PLUGGABLE DATABASE` statement, except `DEFAULT TABLESPACE` and `DEFAULT TEMPORARY TABLESPACE`:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER PLUGGABLE DATABASE')
          CLAUSE ALL EXCEPT = ('DEFAULT TABLESPACE', 'DEFAULT TEMPORARY
TABLESPACE');
```

The following statement disables using the `ALTER SESSION` statement to set or modify `COMMIT_WAIT` or `CURSOR_SHARING`:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SESSION')
          CLAUSE = ('SET')
          OPTION = ('COMMIT_WAIT', 'CURSOR_SHARING');
```

The following statement disables using the `ALTER SYSTEM` statement to set or modify the value of `PDB_FILE_NAME_CONVERT`. It also sets the default value for `PDB_FILE_NAME_CONVERT` to `'cdb1_pdb0', 'cdb1_pdb1'`. This default value will take effect the next time the PDB is closed and reopened.

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SYSTEM')
          CLAUSE = ('SET')
          OPTION = ('PDB_FILE_NAME_CONVERT')
          VALUE = ('cdb1_pdb0', 'cdb1_pdb1');
```

The following statement disables using the `ALTER SYSTEM` statement to set or modify the value of `CPU_COUNT` to a value less than `8`:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SYSTEM')
          CLAUSE = ('SET')
          OPTION = ('CPU_COUNT')
          MINVALUE = '8';
```

The following statement disables using the `ALTER SYSTEM` statement to set or modify the value of `CPU_COUNT` to a value greater than `2`:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SYSTEM')
          CLAUSE = ('SET')
          OPTION = ('CPU_COUNT')
          MAXVALUE = '2';
```

The following statement disables using the `ALTER SYSTEM` statement to set or modify the value of `CPU_COUNT` to a value less than `2` or greater than `6`:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SYSTEM')
          CLAUSE = ('SET')
          OPTION = ('CPU_COUNT')
          MINVALUE = '2'
          MAXVALUE = '6';
```

Enabling SQL Statements for PBB Lockdown Profiles: Examples

The following statement enables all statements except `ALTER DATABASE`:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE STATEMENT ALL EXCEPT = ('ALTER DATABASE');
```

The following statement enables the `ALTER DATABASE MOUNT` and `ALTER DATABASE OPEN` statements:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE STATEMENT = ('ALTER DATABASE')
           CLAUSE = ('MOUNT', 'OPEN');
```

The following statement enables all clauses of the `ALTER PLUGGABLE DATABASE` statement, except `DEFAULT TABLESPACE` and `DEFAULT TEMPORARY TABLESPACE`:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE STATEMENT = ('ALTER PLUGGABLE DATABASE')
         CLAUSE ALL EXCEPT = ('DEFAULT TABLESPACE', 'DEFAULT TEMPORARY
TABLESPACE');
```

The following statement enables using the `ALTER SESSION` statement to set or modify `COMMIT_WAIT` or `CURSOR_SHARING`:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE STATEMENT = ('ALTER SESSION')
         CLAUSE = ('SET')
         OPTION = ('COMMIT_WAIT', 'CURSOR_SHARING');
```

ALTER MATERIALIZED VIEW

Purpose

A materialized view is a database object that contains the results of a query. The `FROM` clause of the query can name tables, views, and other materialized views. Collectively these source objects are called **master tables** (a replication term) or **detail tables** (a data warehousing term). This reference uses the term master tables for consistency. The databases containing the master tables are called the **master databases**.

Use the `ALTER MATERIALIZED VIEW` statement to modify an existing materialized view in one or more of the following ways:

- To change its storage characteristics
- To change its refresh method, mode, or time
- To alter its structure so that it is a different type of materialized view
- To enable or disable query rewrite

> **Note:**
>
> The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

> **See Also:**
>
> - CREATE MATERIALIZED VIEW for more information on creating materialized views
> - *Oracle Database Administrator's Guide* for information on materialized views in a replication environment
> - *Oracle Database Data Warehousing Guide* for information on materialized views in a data warehousing environment

Prerequisites

The materialized view must be in your own schema, or you must have the `ALTER ANY MATERIALIZED VIEW` system privilege.

To enable a materialized view for query rewrite:

- If all of the master tables in the materialized view are in your schema, then you must have the `QUERY REWRITE` privilege.
- If any of the master tables are in another schema, then you must have the `GLOBAL QUERY REWRITE` privilege.
- If the materialized view is in another user's schema, then both you and the owner of that schema must have the appropriate `QUERY REWRITE` privilege, as described in the preceding two items. In addition, the owner of the materialized view must have `SELECT` access to any master tables that the materialized view owner does not own.

To specify an edition in the *`evaluation_edition_clause`* or the *`unusable_editions_clause`*, you must have the `USE` privilege on the edition.

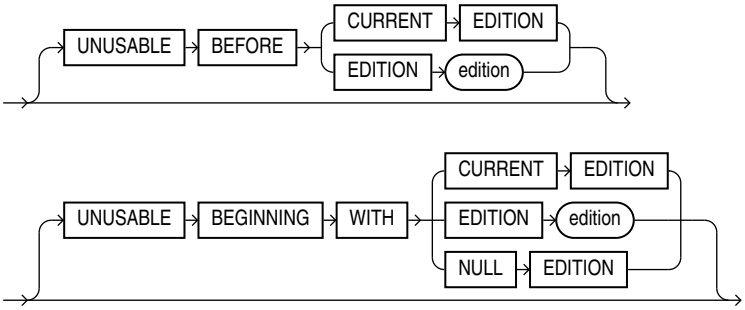
***unusable_editions_clause*::=**



Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing materialized view.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

schema

Specify the schema containing the materialized view. If you omit *`schema`*, then Oracle Database assumes the materialized view is in your own schema.

materialized_view

Specify the name of the materialized view to be altered.

physical_attributes_clause

Specify new values for the `PCTFREE`, `PCTUSED`, and `INITRANS` parameters (or, when used in the `USING INDEX` clause, for the `INITRANS` parameter only) and the storage characteristics for the materialized view. Refer to ALTER TABLE for information on the `PCTFREE`, `PCTUSED`, and `INITRANS` parameters and to storage_clause for information about storage characteristics.

modify_mv_column_clause

Use this clause to encrypt or decrypt this column of the materialized view. Refer to the `CREATE TABLE` clause *encryption_spec* for information on this clause.

table_compression

Use the *`table_compression`* clause to instruct Oracle Database whether to compress data segments to reduce disk and memory use. Refer to the *table_compression* clause of `CREATE TABLE` for the full semantics of this clause.

inmemory_table_clause

Use the *`inmemory_table_clause`* to enable or disable the materialized view or its columns for the In-Memory Column Store (IM column store), or to change the In-Memory attributes for the materialized view or its columns. This clause has the same semantics here as it has for the `ALTER TABLE` statement. Refer to the *inmemory_table_clause* of `ALTER TABLE` for the full semantics of this clause.

LOB_storage_clause

The *LOB_storage_clause* lets you specify the storage characteristics of a new LOB. LOB storage behaves for materialized views exactly as it does for tables. Refer to the *LOB_storage_clause* (in CREATE TABLE) for information on the LOB storage parameters.

modify_LOB_storage_clause

The *modify_LOB_storage_clause* lets you modify the physical attributes of the LOB attribute *LOB_item* or the LOB object attribute. Modification of LOB storage behaves for materialized views exactly as it does for tables.

> **See Also:**
>
> The *modify_LOB_storage_clause* of ALTER TABLE for information on the LOB storage parameters that can be modified

alter_table_partitioning

The syntax and general functioning of the partitioning clauses for materialized views is the same as for partitioned tables. Refer to *alter_table_partitioning* in the documentation on ALTER TABLE.

Restriction on Altering Materialized View Partitions

You cannot specify the *LOB_storage_clause* or *modify_LOB_storage_clause* within any of the *partitioning_clauses*.

> **Note:**
>
> If you want to keep the contents of the materialized view synchronized with those of the master table, then Oracle recommends that you manually perform a complete refresh of all materialized views dependent on the table after dropping or truncating a table partition.

MODIFY PARTITION UNUSABLE LOCAL INDEXES

Use this clause to mark UNUSABLE all the local index partitions associated with *partition*.

MODIFY PARTITION REBUILD UNUSABLE LOCAL INDEXES

Use this clause to rebuild the unusable local index partitions associated with *partition*.

parallel_clause

The *parallel_clause* lets you change the default degree of parallelism for the materialized view.

For complete information on this clause, refer to *parallel_clause* in the documentation on CREATE TABLE.

logging_clause

Specify or change the logging characteristics of the materialized view. Refer to the *logging_clause* for a full description of this clause.

allocate_extent_clause

The *allocate_extent_clause* lets you explicitly allocate a new extent for the materialized view. Refer to the *allocate_extent_clause* for a full description of this clause.

deallocate_unused_clause

Use the *deallocate_unused_clause* to explicitly deallocate unused space at the end of the materialized view and make the freed space available for other segments. Refer to the *deallocate_unused_clause* for a full description of this clause.

shrink_clause

Use this clause to compact the materialized view segments. For complete information on this clause, refer to *shrink_clause* in the documentation on CREATE TABLE.

CACHE | NOCACHE

For data that will be accessed frequently, CACHE specifies that the blocks retrieved for this table are placed at the most recently used end of the LRU list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables. NOCACHE specifies that the blocks are placed at the least recently used end of the LRU list. Refer to "CACHE | NOCACHE | CACHE READS" in the documentation on CREATE TABLE for more information about this clause.

annotations_clause

The *annotation_name* is an identifier that can have up to 4000 characters. If the annotation name is a reserved word it must be provided in double quotes. When a double quoted identifier is used, the identifier can also contain whitespace characters. However, identifiers that contain only whitespace characters are not accepted.

You can only change annotations at the view level with the ALTER statement. To drop column-level annotations, you must drop and recreate the view.

For the full semantics of the annotations clause see *annotations_clause* of CREATE TABLE.

alter_iot_clauses

Use the *alter_iot_clauses* to change the characteristics of an index-organized materialized view. The keywords and parameters of the components of the *alter_iot_clauses* have the same semantics as in ALTER TABLE, with the restrictions that follow.

Restrictions on Altering Index-Organized Materialized Views

You cannot specify the *mapping_table_clause* or the *prefix_compression* clause of the *index_org_table_clause*.

> **See Also:**
>
> *index_org_table_clause* of `CREATE MATERIALIZED VIEW` for information on creating an index-organized materialized view

USING INDEX Clause

Use this clause to change the value of `INITRANS` and `STORAGE` parameters for the index Oracle Database uses to maintain the materialized view data.

Restriction on the USING INDEX clause

You cannot specify the `PCTUSED` or `PCTFREE` parameters in this clause.

MODIFY *scoped_table_ref_constraint*

Use the `MODIFY` *`scoped_table_ref_constraint`* clause to rescope a `REF` column or attribute to a new table or to an alias for a new column.

Restrictions on Rescoping REF Columns

You can rescope only one `REF` column or attribute in each `ALTER MATERIALIZED VIEW` statement, and this must be the only clause in this statement.

alter_mv_refresh

Use the *`alter_mv_refresh`* clause to change the default method and mode and the default times for automatic refreshes. If the contents of the master tables of a materialized view are modified, then the data in the materialized view must be updated to make the materialized view accurately reflect the data currently in its master table(s). This clause lets you schedule the times and specify the method and mode for Oracle Database to refresh the materialized view.

> **See Also:**
>
> - This clause only sets the default refresh options. For instructions on actually implementing the refresh, refer to *Oracle Database Administrator's Guide* and *Oracle Database Data Warehousing Guide*.
> - *Oracle Database Data Warehousing Guide* to learn how to use refresh statistics to monitor the performance of materialized view refresh operations

FAST Clause

Specify `FAST` for the fast refresh method, which performs the refresh according to the changes that have occurred to the master tables. The changes are stored either in the materialized view log associated with the master table (for conventional DML changes) or in the direct loader log (for direct-path `INSERT` operations).

For both conventional DML changes and for direct-path `INSERT` operations, other conditions may restrict the eligibility of a materialized view for fast refresh.

When you change the refresh method to `FAST` in an `ALTER MATERIALIZED VIEW` statement, Oracle Database does not perform this verification. If the materialized view is not eligible for fast refresh, then Oracle Database returns an error when you attempt to refresh this view.

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for restrictions on fast refresh in replication environments
> - *Oracle Database Data Warehousing Guide* for restrictions on fast refresh in data warehouse environments
> - "Automatic Refresh: Examples"

COMPLETE Clause

Specify `COMPLETE` for the complete refresh method, which is implemented by executing the defining query of the materialized view. If you specify a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

> **See Also:**
>
> "Complete Refresh: Example"

FORCE Clause

Specify `FORCE` if, when a refresh occurs, you want Oracle Database to perform a fast refresh if one is possible or a complete refresh otherwise.

ON COMMIT Clause

Specify `ON COMMIT` if you want a refresh to occur whenever Oracle Database commits a transaction that operates on a master table of the materialized view.

You cannot specify both `ON COMMIT` and `ON DEMAND`. If you specify `ON COMMIT`, then you cannot also specify `START WITH` or `NEXT`.

Restriction on ON COMMIT

This clause is supported only for materialized join views and single-table materialized aggregate views.

ON DEMAND Clause

Specify `ON DEMAND` if you want the materialized view to be refreshed on demand by calling one of the three `DBMS_MVIEW` refresh procedures. If you omit both `ON COMMIT` and `ON DEMAND`, then `ON DEMAND` is the default.

You cannot specify both `ON COMMIT` and `ON DEMAND`. `START WITH` and `NEXT` take precedence over `ON DEMAND`. Therefore, in most circumstances it is not meaningful to specify `ON DEMAND` when you have specified `START WITH` or `NEXT`.

> **See Also:**
>
> - *Oracle Database PL/SQL Packages and Types Reference* for information on these procedures
> - *Oracle Database Data Warehousing Guide* on the types of materialized views you can create by specifying `REFRESH ON DEMAND`

START WITH Clause

Specify `START WITH` *`date`* to indicate a date for the first automatic refresh time.

NEXT Clause

Specify `NEXT` to indicate a date expression for calculating the interval between automatic refreshes.

Both the `START WITH` and `NEXT` values must evaluate to a time in the future. If you omit the `START WITH` value, then Oracle Database determines the first automatic refresh time by evaluating the `NEXT` expression with respect to the creation time of the materialized view. If you specify a `START WITH` value but omit the `NEXT` value, then Oracle Database refreshes the materialized view only once. If you omit both the `START WITH` and `NEXT` values, or if you omit the *`alter_mv_refresh`* entirely, then Oracle Database does not automatically refresh the materialized view.

WITH PRIMARY KEY Clause

Specify `WITH PRIMARY KEY` to change a rowid materialized view to a primary key materialized view. Primary key materialized views allow materialized view master tables to be reorganized without affecting the ability of the materialized view to continue to fast refresh.

For you to specify this clause, the master table must contain an enabled primary key constraint and must have defined on it a materialized view log that logs primary key information.

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for detailed information about primary key materialized views
> - "Primary Key Materialized View: Example"

USING ROLLBACK SEGMENT Clause

This clause is not valid if your database is in automatic undo mode, because in that mode Oracle Database uses undo tablespaces instead of rollback segments. Oracle strongly recommends that you use automatic undo mode. This clause is supported for backward compatibility with replication environments containing older versions of Oracle Database that still use rollback segments.

For complete information on this clause, refer to `CREATE MATERIALIZED VIEW` ... "USING ROLLBACK SEGMENT Clause".

USING ... CONSTRAINTS Clause

This clause has the same semantics in CREATE MATERIALIZED VIEW and ALTER MATERIALIZED VIEW statements. For complete information, refer to "USING ... CONSTRAINTS Clause" in the documentation on CREATE MATERIALIZED VIEW.

evaluation_edition_clause

Use this clause to change the evaluation edition for the materialized view. This clause has the same semantics in CREATE MATERIALIZED VIEW and ALTER MATERIALIZED VIEW statements. For complete information on this clause, refer to *evaluation_edition_clause* in the documentation on CREATE MATERIALIZED VIEW.

Notes on Changing the Evaluation Edition of a Materialized View

The following notes apply when changing the evaluation edition of a materialized view:

- If you change the evaluation edition of a refresh-on-commit materialized view, then Oracle Database performs a complete refresh of the materialized view unless you specify CONSIDER FRESH.
- If you change the evaluation edition of a refresh-on-demand materialized view, then Oracle Database sets the staleness state of the materialized view to STALE unless you specify CONSIDER FRESH.
- For both refresh-on-commit and refresh-on-demand materialized views: If you change the evaluation edition and specify CONSIDER FRESH, then Oracle Database does not update the staleness state of the materialized view and does not rebuild the materialized view. Therefore, you can specify CONSIDER FRESH to indicate that, although the evaluation edition has changed, there is no difference in the results that *subquery* will produce. If the materialized view is stale and in need of either a fast refresh or a complete refresh before this statement is issued, then the state will not be changed and the materialized view may contain bad data.

{ ENABLE | DISABLE } ON QUERY COMPUTATION

This clause lets you control whether the materialized view is a real-time materialized view or a regular materialized view.

- Specify ENABLE ON QUERY COMPUTATION to convert a regular materialized view into a real-time materialized view by enabling on-query computation.
- Specify DISABLE ON QUERY COMPUTATION to convert a real-time materialized view into a regular materialized view by disabling on-query computation.

This clause has the same semantics in CREATE MATERIALIZED VIEW and ALTER MATERIALIZED VIEW statements. For complete information on this clause, refer to { ENABLE | DISABLE } ON QUERY COMPUTATION in the documentation on CREATE MATERIALIZED VIEW.

alter_query_rewrite_clause

Use this clause to specify whether the materialized view is eligible to be used for query rewrite.

ENABLE Clause

Specify ENABLE to enable the materialized view for query rewrite. If you currently specify, or previously specified, the *unusable_editions_clause* for the materialized view, then it is not enabled for query rewrite in the unusable editions.

> **See Also:**
>
> - "Enabling Query Rewrite: Example"
> - *Oracle Database Data Warehousing Guide* to learn how to use refresh statistics to monitor the performance of materialized view refresh operations

Restrictions on Enabling Materialized Views

Enabling materialized views is subject to the following restrictions:

- If the materialized view is in an invalid or unusable state, then it is not eligible for query rewrite in spite of the `ENABLE` mode.
- You cannot enable query rewrite if the materialized view was created totally or in part from a view.
- You can enable query rewrite only if all user-defined functions in the materialized view are `DETERMINISTIC`.

  > **See Also:**
  >
  > CREATE FUNCTION

- You can enable query rewrite only if expressions in the statement are repeatable. For example, you cannot include `CURRENT_TIME` or `USER`.

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for more information on query rewrite

DISABLE Clause

Specify `DISABLE` if you do not want the materialized view to be eligible for use by query rewrite. If a materialized view is in the invalid state, then it is not eligible for use by query rewrite, whether or not it is disabled. However, a disabled materialized view can be refreshed.

unusable_editions_clause

Use this clause to specify the editions in which the materialized view is not eligible for query rewrite. This clause has the same semantics in `CREATE MATERIALIZED VIEW` and `ALTER MATERIALIZED VIEW` statements. For complete information on this clause, refer to *unusable_editions_clause* in the documentation on `CREATE MATERIALIZED VIEW`.

Cursors that use the materialized view for query rewrite and were compiled in an edition that is made unusable will be invalidated.

ENABLE | DISABLE CONCURRENT REFRESH

Enable concurrent refresh to refresh the same on-commit atomic materialized view across mulitple sessions. Multiple sessions which have DML on a base table can refresh the MV concurrently. There are no limitations on how many materialized views can be refreshed.

Concurrent refresh is disabled by default. You must explictly enable it on the materialized view. Note that you can enable it only on on-commit materialized views.

> **See Also:**
>
> *Refreshing Materialized Views* of the *Oracle Database Data Warehousing Guide*.

COMPILE

Specify `COMPILE` to explicitly revalidate a materialized view. If an object upon which the materialized view depends is dropped or altered, then the materialized view remains accessible, but it is invalid for query rewrite. You can use this clause to explicitly revalidate the materialized view to make it eligible for query rewrite.

If the materialized view fails to revalidate, then it cannot be refreshed or used for query rewrite.

> **See Also:**
>
> "Compiling a Materialized View: Example"

CONSIDER FRESH

This clause lets you manage the staleness state of a materialized view after changes have been made to its master tables. `CONSIDER FRESH` directs Oracle Database to consider the materialized view fresh and therefore eligible for query rewrite in the `TRUSTED` or `STALE_TOLERATED` modes.

> **Caution:**
>
> The `CONSIDER FRESH` clause also directs Oracle Database to no longer apply any rows in a materialized view log or Partition Change Tracking changes to the materialized view prior to the issuance of the `CONSIDER FRESH` clause. In other words, the pending changes will be ignored and deleted, not applied to the materialized view. This may result in the materialized view containing more or less data than the base table.

Because Oracle Database cannot guarantee the freshness of the materialized view, query rewrite in `ENFORCED` mode is not supported. This clause also sets the staleness state of the materialized view to `UNKNOWN`. The staleness state is displayed in the `STALENESS` column of the `ALL_MVIEWS`, `DBA_MVIEWS`, and `USER_MVIEWS` data dictionary views.

A materialized view is stale if changes have been made to the contents of any of its master tables. This clause directs Oracle Database to assume that the materialized view is fresh and that no such changes have been made. Therefore, actual updates to those tables pending refresh are purged with respect to the materialized view.

> **See Also:**
>
> - *Oracle Database Data Warehousing Guide* for more information on query rewrite and the implications of performing partition maintenance operations on master tables
> - "CONSIDER FRESH: Example"

Examples

Automatic Refresh: Examples

The following statement changes the default refresh method for the `sales_by_month_by_state` materialized view (created in "Creating Materialized Aggregate Views: Example") to `FAST`:

```
ALTER MATERIALIZED VIEW sales_by_month_by_state
   REFRESH FAST;
```

The next automatic refresh of the materialized view will be a fast refresh provided it is a simple materialized view and its master table has a materialized view log that was created before the materialized view was created or last refreshed.

Because the `REFRESH` clause does not specify `START WITH` or `NEXT` values, Oracle Database will use the refresh intervals established by the `REFRESH` clause when the `sales_by_month_by_state` materialized view was created or last altered.

The following statement establishes a new interval between automatic refreshes for the `sales_by_month_by_state` materialized view:

```
ALTER MATERIALIZED VIEW sales_by_month_by_state
   REFRESH NEXT SYSDATE+7;
```

Because the `REFRESH` clause does not specify a `START WITH` value, the next automatic refresh occurs at the time established by the `START WITH` and `NEXT` values specified when the `sales_by_month_by_state` materialized view was created or last altered.

At the time of the next automatic refresh, Oracle Database refreshes the materialized view, evaluates the `NEXT` expression `SYSDATE`+7 to determine the next automatic refresh time, and continues to refresh the materialized view automatically once a week. Because the `REFRESH` clause does not explicitly specify a refresh method, Oracle Database continues to use the refresh method specified by the `REFRESH` clause of the `CREATE MATERIALIZED VIEW` or most recent `ALTER MATERIALIZED VIEW` statement.

CONSIDER FRESH: Example

The following statement instructs Oracle Database that materialized view `sales_by_month_by_state` should be considered fresh. This statement allows `sales_by_month_by_state` to be eligible for query rewrite in `TRUSTED` mode even after you have performed partition maintenance operations on the master tables of `sales_by_month_by_state`:

```
ALTER MATERIALIZED VIEW sales_by_month_by_state CONSIDER FRESH;
```

As a result of the preceding statement, any partition maintenance operations that were done to the base table since the last refresh of the materialized view will not be applied to the materialized view. For example, the add, drop, or change of data in a partition in the base table

will not be reflected in the materialized view if `CONSIDER FRESH` is used before the next refresh of the materialized view. Refer to CONSIDER FRESH for more information.

> **See Also:**
>
> "Splitting Table Partitions: Examples" for a partitioning maintenance example that would require this `ALTER MATERIALIZED VIEW` example

Complete Refresh: Example

The following statement specifies a new refresh method, a new `NEXT` refresh time, and a new interval between automatic refreshes of the `emp_data` materialized view (created in "Periodic Refresh of Materialized Views: Example"):

```
ALTER MATERIALIZED VIEW emp_data
   REFRESH COMPLETE
   START WITH TRUNC(SYSDATE+1) + 9/24
   NEXT SYSDATE+7;
```

The `START WITH` value establishes the next automatic refresh for the materialized view to be 9:00 a.m. tomorrow. At that point, Oracle Database performs a complete refresh of the materialized view, evaluates the `NEXT` expression, and subsequently refreshes the materialized view every week.

Enabling Query Rewrite: Example

The following statement enables query rewrite on the materialized view `emp_data` and implicitly revalidates it:

```
ALTER MATERIALIZED VIEW emp_data
   ENABLE QUERY REWRITE;
```

Primary Key Materialized View: Example

The following statement changes the rowid materialized view `order_data` (created in "Creating Rowid Materialized Views: Example") to a primary key materialized view. This example requires that you have already defined a materialized view log with a primary key on `order_data`.

```
ALTER MATERIALIZED VIEW order_data
   REFRESH WITH PRIMARY KEY;
```

Compiling a Materialized View: Example

The following statement revalidates the materialized view `store_mv`:

```
ALTER MATERIALIZED VIEW order_data COMPILE;
```

Drop Annotation from View: Example

The following example drops annotation `Snapshot` from view `MView1`:

```
ALTER MATERIALIZED VIEW MView1 ANNOTATIONS(DROP Snapshot);
```

ALTER MATERIALIZED VIEW LOG

Purpose

A **materialized view log** is a table associated with the master table of a materialized view. Use the `ALTER MATERIALIZED VIEW LOG` statement to alter the storage characteristics or type of an existing materialized view log.

> **Note:**
>
> The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

> **See Also:**
>
> - CREATE MATERIALIZED VIEW LOG for information on creating a materialized view log
> - ALTER MATERIALIZED VIEW for more information on materialized views, including refreshing them
> - CREATE MATERIALIZED VIEW for a description of the various types of materialized views

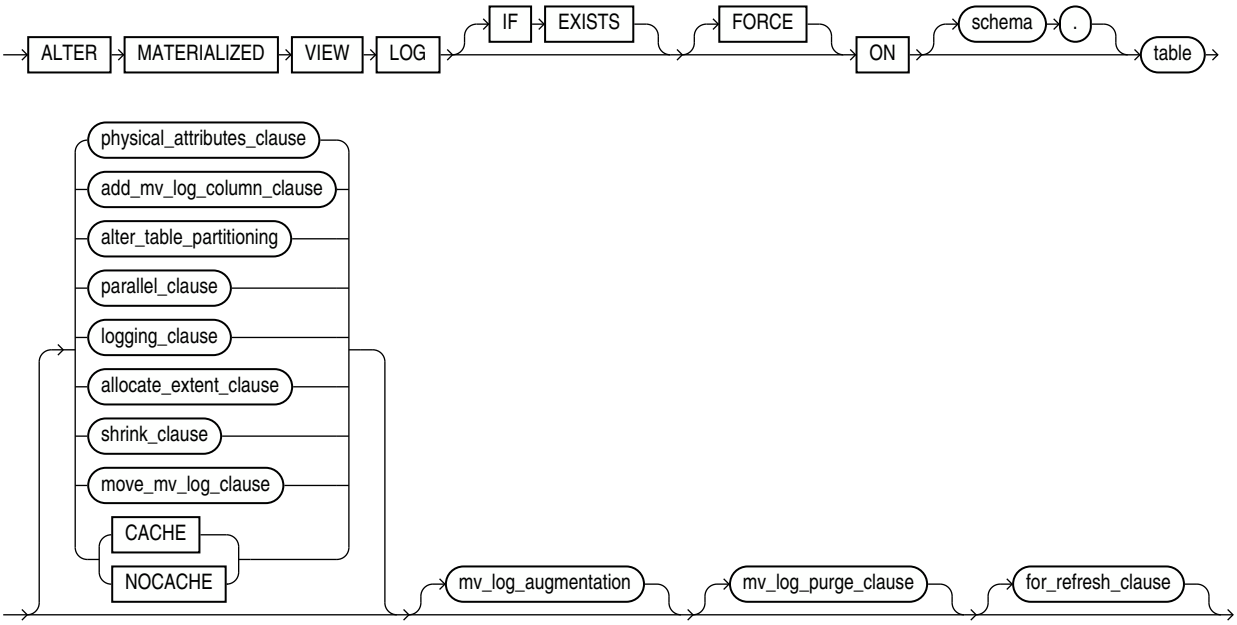
Prerequisites

You must be the owner of the master table, or you must have the `READ` or `SELECT` privilege on the master table and the `ALTER` privilege on the materialized view log.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for detailed information about the prerequisites for `ALTER MATERIALIZED VIEW LOG`

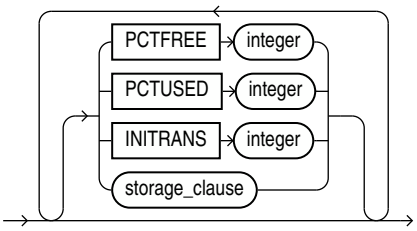
Syntax

***alter_materialized_view_log*::=**



(*physical_attributes_clause*::=, *add_mv_log_column_clause*::=, *alter_table_partitioning*::= (in `ALTER TABLE`), *parallel_clause*::=, *logging_clause*::=, *allocate_extent_clause*::=, *shrink_clause*::=, *move_mv_log_clause*::=, *mv_log_augmentation*::=, *mv_log_purge_clause*::=, *for_refresh_clause*::=)

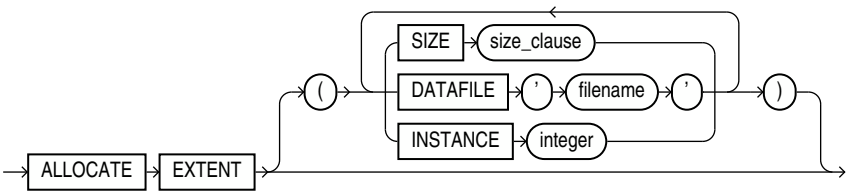
***physical_attributes_clause*::=**



storage_clause::=

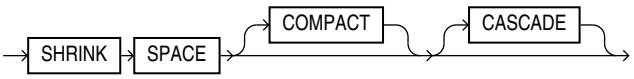
***add_mv_log_column_clause*::=**

***allocate_extent_clause*::=**

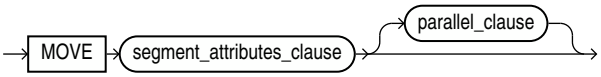


(*size_clause*::=)

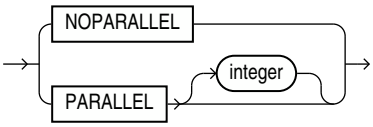
***shrink_clause*::=**



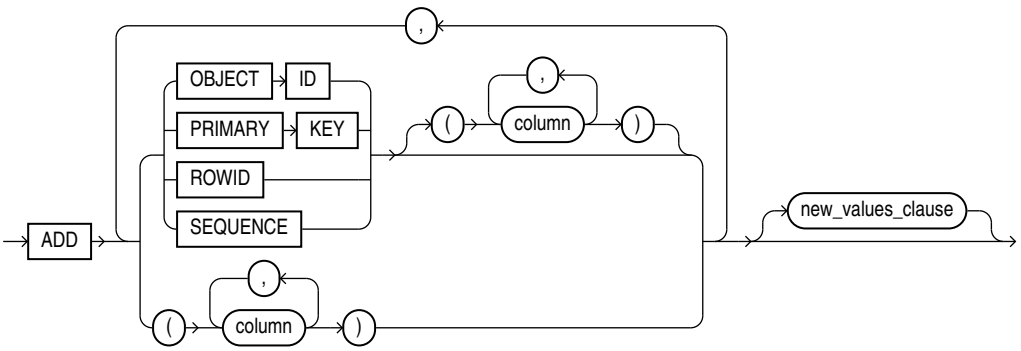
***move_mv_log_clause*::=**



***parallel_clause*::=**

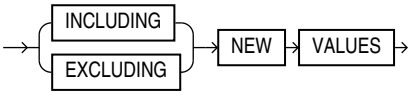


***mv_log_augmentation*::=**

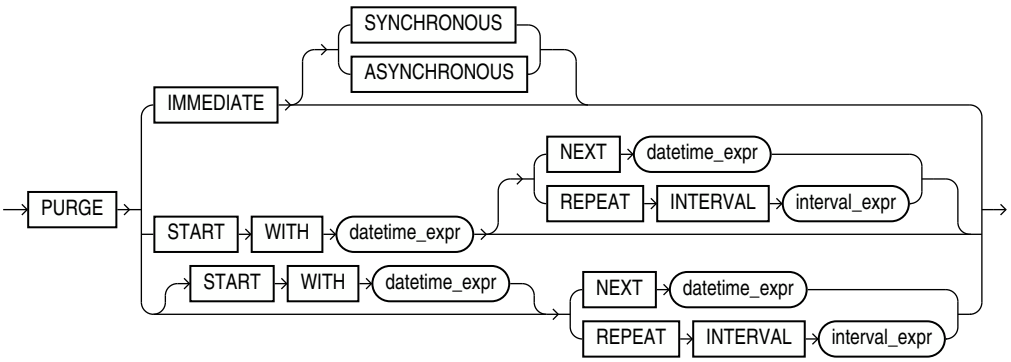


(*new_values_clause*::=

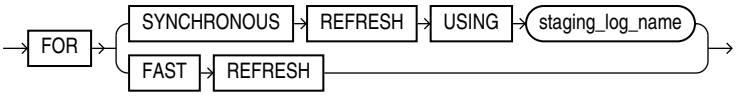
***new_values_clause*::=**



***mv_log_purge_clause*::=**



***for_refresh_clause*::=**



Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

FORCE

If you specify `FORCE` and any items specified with the `ADD` clause have already been specified for the materialized view log, then Oracle Database does not return an error, but silently ignores the existing elements and adds to the materialized view log any items that do not already exist in the log. Likewise, if you specify `INCLUDING NEW VALUES` and that attribute has already been specified for the materialized view log, Oracle Database ignores the redundancy and does not return an error.

schema

Specify the schema containing the master table. If you omit *`schema`*, then Oracle Database assumes the materialized view log is in your own schema.

table

Specify the name of the master table associated with the materialized view log to be altered.

physical_attributes_clause

The *physical_attributes_clause* lets you change the value of the PCTFREE, PCTUSED, and INITRANS parameters and the storage characteristics for the materialized view log, the partition, the overflow data segment, or the default characteristics of a partitioned materialized view log.

Restriction on Materialized View Log Physical Attributes

You cannot use the *storage_clause* to modify extent parameters if the materialized view log resides in a locally managed tablespace. Refer to CREATE TABLE for a description of these parameters.

add_mv_log_column_clause

When you add a column to the master table of the materialized view log, the database does not automatically add a column to the materialized view log. Therefore, use this clause to add a column to the materialized view log. Oracle Database will encrypt the newly added column if the corresponding column of the master table is encrypted.

alter_table_partitioning

The syntax and general functioning of the partitioning clauses is the same as described for the ALTER TABLE statement. Refer to *alter_table_partitioning* in the documentation on ALTER TABLE.

Restrictions on Altering Materialized View Log Partitions

Altering materialized view log partitions is subject to the following restrictions:

- You cannot use the *LOB_storage_clause* or *modify_LOB_storage_clause* when modifying partitions of a materialized view log.
- If you attempt to drop, truncate, or exchange a materialized view log partition, then Oracle Database raises an error.

parallel_clause

The *parallel_clause* lets you specify whether parallel operations will be supported for the materialized view log.

For complete information on this clause, refer to *parallel_clause* in the documentation on CREATE TABLE.

logging_clause

Specify the logging attribute of the materialized view log. Refer to the *logging_clause* for a full description of this clause.

allocate_extent_clause

Use the *allocate_extent_clause* to explicitly allocate a new extent for the materialized view log. Refer to *allocate_extent_clause* for a full description of this clause.

shrink_clause

Use this clause to compact the materialized view log segments. For complete information on this clause, refer to *shrink_clause* in the documentation on `CREATE TABLE`.

move_mv_log_clause

Use the `MOVE` clause to move the materialized view log table to a different tablespace, to change other segment or storage attributes of the materialized view log, or to change the parallelism of the materialized view log.

Restriction on Moving Materialized View Logs

The `ENCRYPT` clause of the *storage_clause* of *segment_attributes* is not valid for materialized view logs.

CACHE | NOCACHE Clause

For data that will be accessed frequently, `CACHE` specifies that the blocks retrieved for this log are placed at the most recently used end of the LRU list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables. `NOCACHE` specifies that the blocks are placed at the least recently used end of the LRU list. Refer to "CACHE | NOCACHE | CACHE READS" in the documentation on `CREATE TABLE` for more information about this clause.

mv_log_augmentation

Use the `ADD` clause to augment the materialized view log so that it records the primary key values, rowid values, object ID values, or a sequence when rows in the materialized view master table are changed. This clause can also be used to record additional columns.

To stop recording any of this information, you must first drop the materialized view log and then re-create it. Dropping the materialized view log and then re-creating it forces a complete refresh for each of the existing materialized views that depend on the master table on its next refresh.

Restriction on Augmenting Materialized View Logs

You can specify only one `PRIMARY KEY`, one `ROWID`, one `OBJECT ID`, one `SEQUENCE`, and each column in the column list once for each materialized view log. You can specify only a single occurrence of `PRIMARY KEY`, `ROWID`, `OBJECT ID`, `SEQUENCE`, and column list within this `ALTER` statement. Also, if any of these values was specified at create time (either implicitly or explicitly), you cannot specify that value in this `ALTER` statement unless you use the `FORCE` option.

OBJECT ID

Specify `OBJECT ID` if you want the appropriate object identifier of all rows that are changed to be recorded in the materialized view log.

Restriction on the OBJECT ID clause

You can specify `OBJECT ID` only for logs on object tables, and you cannot specify it for storage tables.

PRIMARY KEY

Specify `PRIMARY KEY` if you want the primary key values of all rows that are changed to be recorded in the materialized view log.

ROWID

Specify `ROWID` if you want the rowid values of all rows that are changed to be recorded in the materialized view log.

SEQUENCE

Specify `SEQUENCE` to indicate that a sequence value providing additional ordering information should be recorded in the materialized view log.

column

Specify the additional columns whose values you want to be recorded in the materialized view log for all rows that are changed. Typically these columns are filter columns (non-primary-key columns referenced by subquery materialized views) and join columns (non-primary-key columns that define a join in the `WHERE` clause of the subquery).

> **See Also:**
>
> - CREATE MATERIALIZED VIEW for details on explicit and implicit inclusion of materialized view log values
> - *Oracle Database Administrator's Guide* for more information about filter columns and join columns
> - "Rowid Materialized View Log: Example"

NEW VALUES Clause

The `NEW VALUES` clause lets you specify whether Oracle Database saves both old and new values for update DML operations in the materialized view log. The value you set in this clause applies to all columns in the log, not only to columns you may have added in this `ALTER MATERIALIZED VIEW LOG` statement.

INCLUDING

Specify `INCLUDING` to save both new and old values in the log. If this log is for a table on which you have a single-table materialized aggregate view, and if you want the materialized view to be eligible for fast refresh, then you must specify `INCLUDING`.

EXCLUDING

Specify `EXCLUDING` to disable the recording of new values in the log. You can use this clause to avoid the overhead of recording new values.

If you have a fast-refreshable single-table materialized aggregate view defined on this table, then do not specify `EXCLUDING NEW VALUES` unless you first change the refresh mode of the materialized view to something other than `FAST`.

> **See Also:**
>
> "Materialized View Log EXCLUDING NEW VALUES: Example"

mv_log_purge_clause

Use this clause alter the purge attributes of the materialized view log in the following ways:

- Change the purge from `IMMEDIATE SYNCHRONOUS` to `IMMEDIATE ASYNCHRONOUS` or from `IMMEDIATE ASYNCHRONOUS` to `IMMEDIATE SYNCHRONOUS`
- Change the purge from `IMMEDIATE` to scheduled or from scheduled to `IMMEDIATE`
- Specify a new start time and a new `next` time and `interval`

If you are altering purge from scheduled to `IMMEDIATE`, then the scheduled purged job associated with that materialized view log is dropped. If you are altering purge from `IMMEDIATE` to scheduled, then a purge job is created with the attributes provided. If you are altering scheduled purge attributes, then only those attributes specified will be changed in the scheduler purge job.

You must specify `FORCE` if you are altering log purge to its current state (that is, you are not making any change), unless you are changing scheduled purge attributes.

To learn whether the purge time or interval has already been set for this materialized view log, query the `*_MVIEW_LOGS` data dictionary views. See the `CREATE MATERIALIZED VIEW LOG` clause *mv_log_purge_clause* for the full semantics of this clause.

for_refresh_clause

Use this clause to change the refresh method for which the materialized view log will be used.

FOR SYNCHRONOUS REFRESH

Specify this clause to change from fast refresh to synchronous refresh, or complete refresh to synchronous refresh. A staging log will be created.

If you are changing from fast refresh, then ensure that the following conditions are satisfied before using this clause:

- All changes in the materialized view log have been consumed.
- Any refresh-on-demand materialized views associated with the master table have been refreshed.
- Any refresh-on-commit materialized views associated with the master table have been converted to refresh-on-demand materialized views.

After you use this clause, you cannot perform DML operations directly on the master table. You must use the procedures in the `DBMS_SYNC_REFRESH` package to prepare and execute change data operations.

FOR FAST REFRESH

Specify this clause to change from synchronous refresh to fast refresh, or complete refresh to fast refresh. A materialized view log will be created.

If you are changing from synchronous refresh to fast refresh, then ensure that all changes in the staging log have been consumed before using this clause.

After you use this clause, you can perform DML operations directly on the master table.

See the `CREATE MATERIALIZED VIEW LOG` clause *for_refresh_clause* for the full semantics of this clause.

Examples

Rowid Materialized View Log: Example

The following statement alters an existing primary key materialized view log to also record rowid information:

```
ALTER MATERIALIZED VIEW LOG ON order_items ADD ROWID;
```

Materialized View Log EXCLUDING NEW VALUES: Example

The following statement alters the materialized view log on `hr.employees` by adding a filter column and excluding new values. Any materialized aggregate views that use this log will no longer be fast refreshable. However, if fast refresh is no longer needed, this action avoids the overhead of recording new values:

```
ALTER MATERIALIZED VIEW LOG ON employees
   ADD (commission_pct)
   EXCLUDING NEW VALUES;
```

ALTER MATERIALIZED ZONEMAP

Purpose

Use the `ALTER MATERIALIZED ZONEMAP` statement to modify an existing zone map in one of the following ways:

- To change its attributes
- To change its default refresh method and mode
- To enable or disable its use for pruning
- To compile it, rebuild it, or make it unusable

> **See Also:**
>
> - CREATE MATERIALIZED ZONEMAP for information on creating zone maps
> - *Oracle Database Data Warehousing Guide* for more information on zone maps

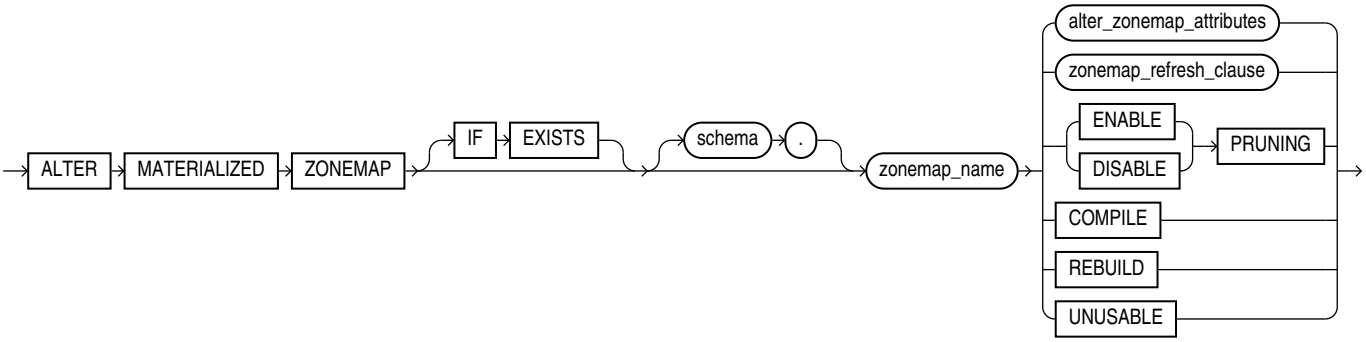
Prerequisites

The zone map must be in your own schema or you must have the `ALTER ANY MATERIALIZED VIEW` system privilege.

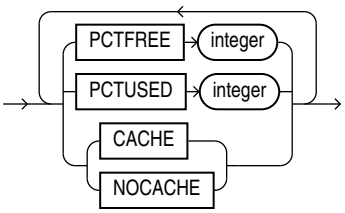
The user who owns the schema containing the zone map must have access to any base tables of the zone map that reside outside of that schema, either through a `READ` or `SELECT` object privilege on each of the tables, or through the `READ ANY TABLE` or `SELECT ANY TABLE` system privilege.

Syntax

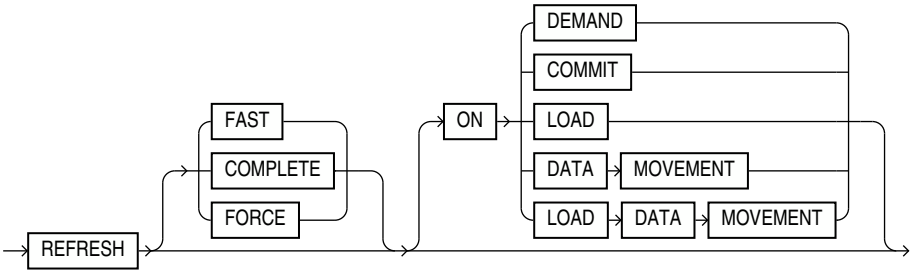
***alter_materialized_zonemap*::=**



***alter_zonemap_attributes*::=**



***zonemap_refresh_clause*::=**



> **Note:**
>
> When specifying the *zonemap_refresh_clause*, you must specify at least one clause after the REFRESH keyword.

Semantics

IF EXISTS

Specify IF EXISTS to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

schema

Specify the schema containing the zone map. If you omit *`schema`*, then Oracle Database assumes the zone map is in your own schema.

zonemap_name

Specify the name of the zone map to be altered.

alter_zonemap_attributes

Use this clause to modify the following attributes for the zone map: `PCTFREE`, `PCTUSED`, and `CACHE` or `NOCACHE`. These attributes have the same semantics for `ALTER MATERIALIZED ZONEMAP` and `CREATE MATERIALIZED ZONEMAP`. For complete information on these attributes, refer to PCTFREE, PCTUSED, and CACHE | NOCACHE in the documentation on `CREATE MATERIALIZED ZONEMAP`.

zonemap_refresh_clause

Use this clause to modify the default refresh method and mode for the zone map. This clause has the same semantics for `ALTER MATERIALIZED ZONEMAP` and `CREATE MATERIALIZED ZONEMAP`. For complete information on this clause, refer to *zonemap_refresh_clause* in the documentation on `CREATE MATERIALIZED ZONEMAP`.

ENABLE | DISABLE PRUNING

Use this clause to enable or disable use of the zone map for pruning. This clause has the same semantics for `ALTER MATERIALIZED ZONEMAP` and `CREATE MATERIALIZED ZONEMAP`. For complete information on this clause, refer to ENABLE | DISABLE PRUNING in the documentation on `CREATE MATERIALIZED ZONEMAP`

COMPILE

This clause lets you explicitly compile the zone map. This operation validates the zone map after a DDL operation changes the structure of one or more of its base tables. It is usually not necessary to issue this clause because Oracle database automatically compiles a zone map that requires compilation before using it. However, if you would like to explicitly compile a zone map, then you can use this clause to do so.

The result of compiling a zone map depends on whether a base table is changed in a way that affects the zone map. For example, if a column is added to a base table, then the zone map will be valid after compilation because the change does not affect the zone map. However, if a column that is included in the defining subquery of the zone map is dropped from a base table, then the zone map will be invalid after compilation.

You can determine if a zone map requires compilation by querying the `COMPILE_STATE` column of the `ALL_`, `DBA_`, and `USER_ZONEMAPS` data dictionary views. If the value of the column is `NEEDS_COMPILE`, then the zone map requires compilation.

REBUILD

This clause lets you explicitly rebuild the zone map. This operation refreshes the data in the zone map. This clause is useful in the following situations:

- You can use this clause to refresh the data for a refresh-on-demand zone map. Refer to the ON DEMAND clause in the documentation on CREATE MATERIALIZED ZONEMAP for more information.
- You must issue this clause after an EXCHANGE PARTITION operation on one of the base tables of a zone map, regardless of the default refresh mode of the zone map.
- If a zone map is marked unusable, then you must issue this clause to mark it usable. You can determine if a zone map is marked unusable by querying the UNUSABLE column of the ALL_, DBA_, and USER_ZONEMAPS data dictionary views.

UNUSABLE

Specify this clause to make the zone map unusable. Subsequent queries will not use the zone map and the database will no longer maintain the zone map. You can make the zone map usable again by issuing an ALTER MATERIALIZED ZONEMAP ... REBUILD statement.

Examples

Modifying Zone Map Attributes: Example

The following statement modifies the PCTFREE and PCTUSED attributes of zone map sales_zmap, and modifies the zone map so that it does not use caching:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  PCTFREE 20 PCTUSED 50 NOCACHE;
```

Modifying the Default Refresh Method and Mode for a Zone Map: Example

The following statement changes the default refresh method to FAST and the default refresh mode to ON COMMIT for zone map sales_zmap:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  REFRESH FAST ON COMMIT;
```

Disabling Use of a Zone Map for Pruning: Example

The following statement disables use of zone map sales_zmap for pruning:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  DISABLE PRUNING;
```

Compiling a Zone Map: Example

The following statement compiles zone map sales_zmap:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  COMPILE;
```

Rebuilding a Zone Map: Example

The following statement rebuilds zone map sales_zmap:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  REBUILD;
```

Making a Zone Map Unusable: Example

The following statement makes zone map sales_zmap unusable:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  UNUSABLE;
```

ALTER MLE ENV

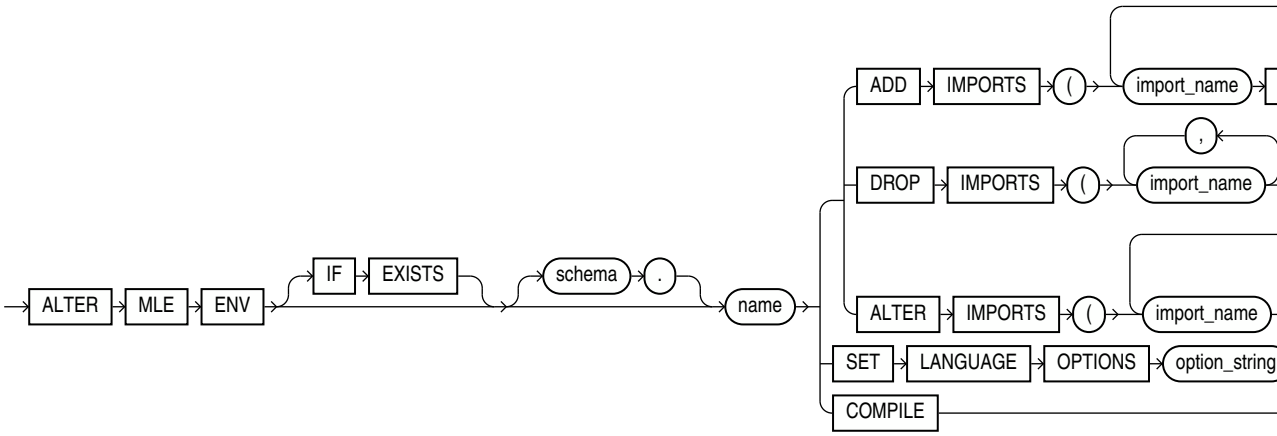
Purpose

Use `ALTER MLE ENV` to alter an exisiting MLE environment. You can add, remove, and alter mappings for import names and set language options.

Prerequisites

You must have the `ALTER ANY MLE` privilege to alter an environment in schemas other than your own. No privilege is needed to alter an environment in your own schema.

Syntax



Semantics

IF EXISTS

The `ALTER MLE MODULE` statement raises an `ORA-04103` error if the module does not exist, or an `ORA-00922` error if an invalid attribute is specified.

schema

Specify the schema containing the MLE module. If you do not specify the schema, then Oracle Database assumes that the module is in your own schema.

ADD IMPORTS Clause

Use `ADD IMPORTS` to add new mappings from import names to MLE module schema objects. Mappings to be added are specified as a comma-separated list enclosed in parentheses. Each element in the list is of the form: *`import-name MODULE [schema]. mle-module-name`*.

The following cases produce errors:

- If the environment already contains one or more of the import names, an `ORA-04109` error is thrown.
- If one or more of the MLE modules does not reside in the same schema as the environment, an `ORA-01031` error is thrown.

DROP IMPORTS Clause

Use `DROP IMPORTS` to remove import names from the environment.

If the environment does nnot contain one or more of the specified import names, an `ORA-04110` error is thrown.

ALTER IMPORTS Clause

Use `ALTER IMPORTS` to update import mappings for each of the specified import names.

The following cases produce errors:

- If the environment does not contain one or more of the import names, an `ORA-04110` error is thrown.
- If one or more of the new MLE modules does not reside in the same schema as the environment, an `ORA-01031` error is thrown.

SET LANGUAGE OPTIONS Clause

Use `LANGUAGE OPTIONS` to specify language options for all execution contexts created with this environment. Language options are specified as a string literal consisting of comma-separated key-value pairs. Language options are only parsed at runtime when an execution context is created using the MLE environment.

If at context creation the language options string turns out to be invalid (invalid format, unsupported options), an `ORA-04152` error is thrown.

Example

The following example modifies an exisiting environment myenv by enabling JavaScript in strict mode:

```
ALTER MLE ENV scott."myenv" SET LANGUAGE OPTIONS 'js.strict=
true ';
```

COMPILE Clause

Use `COMPILE` to explicitly recompile an MLE environment. You can use this clause to revalidate an environment that has become invalid and thereby catch errors before run time.

> **See Also:**
>
> - *MLE JavaScript Modules and Environments*
> - CREATE MLE ENV
> - DROP MLE ENV

ALTER MLE MODULE

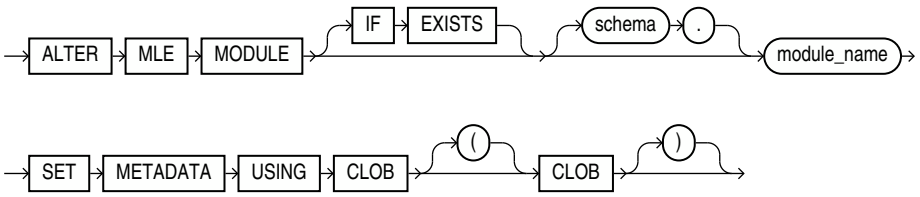
Purpose

Use `ALTER MLE MODULE` to add metadata to existing MLE modules in the database.

Prerequisites

To alter MLE modules in another schema you need the `ALTER ANY MLE` system privilege. No privileges are required to alter MLE modules in your own schema.

Syntax



Semantics

IF EXISTS

The `ALTER MLE MODULE` statement raises an `ORA-04103` error if the module does not exist, or an `ORA-00922` error if an invalid attribute is specified.

schema

Specify the schema containing the MLE module. If you do not specify the schema, then Oracle Database assumes that the module is in your own schema.

module_name

`module_name` refers to the name of the MLE module.

CLOB

`CLOB` refers to the text you can attach to an MLE module. You can use it to refer to a commit in a version control system or as a part of a Software Bill of Materials. The `CLOB` contents are freeform metadata that can be attached to the MLE module. The metadata does not impact module functionality in any way. Oracle recommends that the metadata be used to record version information for the MLE module, e.g., the commit in a version control system that corresponds to the deployed version of the module, or a Software Bill of Materials for the module, for example the contents of `package-lock.json` for a bundled JavaScript module.

Examples

The following example attaches metadata as `JSON` to MLE module `myMLEModule`:

```
ALTER MLE MODULE myMLEModule
SET METADATA USING CLOB (
SELECT JSON(
  '{
       "name": "value",
       "version": "1.2.0",
       "commitHash": "23fas4h",
       "projectName": "Database Backend"
  }')
)
```

> **See Also:**
>
> - *MLE JavaScript Modules and Environments*
> - CREATE MLE MODULE
> - DROP MLE MODULE

ALTER OPERATOR

Purpose

Use the `ALTER OPERATOR` statement to add bindings to, drop bindings from, or compile an existing operator.

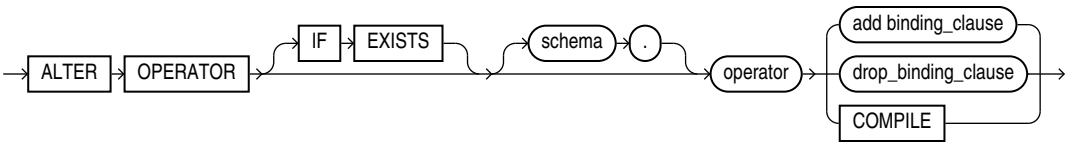
> **See Also:**
>
> CREATE OPERATOR

Prerequisites

The operator must already have been created by a previous `CREATE OPERATOR` statement. The operator must be in your own schema or you must have the `ALTER ANY OPERATOR` system privilege. You must have the `EXECUTE` object privilege on the operators and functions referenced in the `ALTER OPERATOR` statement.

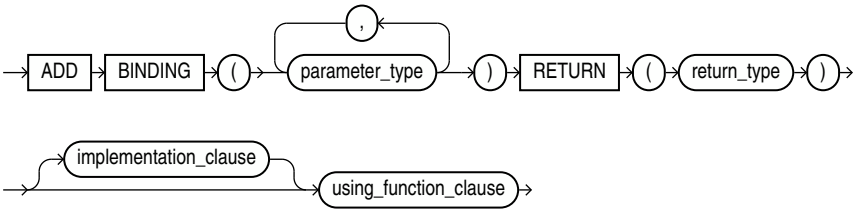
Syntax

***alter_operator*::=**



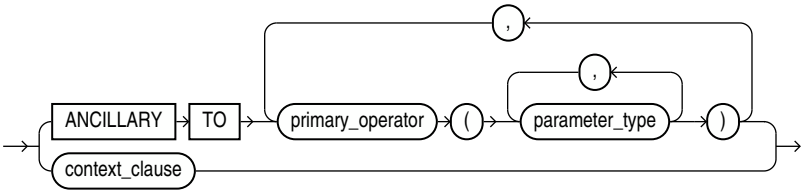
(*add_binding_clause*::=, *drop_binding_clause*::=)

***add_binding_clause*::=**



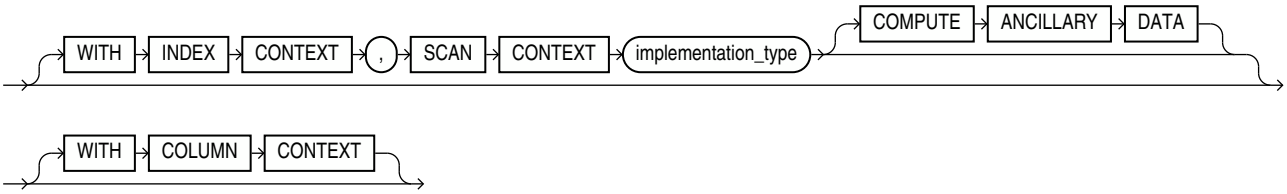
(*implementation_clause*::=, *using_function_clause*::=)

***implementation_clause*::=**

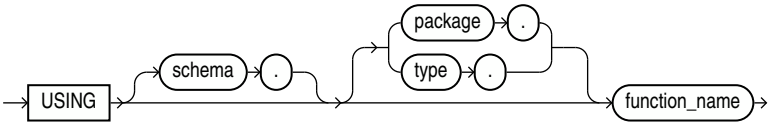


(*context_clause*::=)

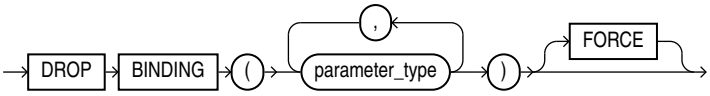
***context_clause*::=**



***using_function_clause*::=**



***drop_binding_clause*::=**



Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

schema

Specify the schema containing the operator. If you omit this clause, then Oracle Database assumes the operator is in your own schema.

operator

Specify the name of the operator to be altered.

add_binding_clause

Use this clause to add an operator binding and specify its parameter data types and return type. The signature must be different from the signature of any existing binding for this operator.

If a binding of an operator is associated with an indextype and you add another binding to the operator, then Oracle Database does not automatically associate the new binding with the indextype. If you want to make such an association, then you must issue an explicit `ALTER INDEXTYPE ... ADD OPERATOR` statement.

implementation_clause

This clause has the same semantics in `CREATE OPERATOR` and `ALTER OPERATOR` statements. For full information, refer to *implementation_clause* in the documentation on `CREATE OPERATOR`.

context_clause

This clause has the same semantics in `CREATE OPERATOR` and `ALTER OPERATOR` statements. For full information, refer to context_clause in the documentation on `CREATE OPERATOR`.

using_function_clause

This clause has the same semantics in `CREATE OPERATOR` and `ALTER OPERATOR` statements. For full information, refer to *using_function_clause* in the documentation on `CREATE OPERATOR`.

drop_binding_clause

Use this clause to specify the list of parameter data types of the binding you want to drop from the operator. You must specify `FORCE` if the binding has any dependent objects, such as an indextype or an ancillary operator binding. If you specify `FORCE`, then Oracle Database marks `INVALID` all objects that are dependent on the binding. The dependent objects are revalidated the next time they are referenced in a DDL or DML statement or a query.

You cannot use this clause to drop the only binding associated with this operator. Instead you must use the `DROP OPERATOR` statement. Refer to DROP OPERATOR for more information.

COMPILE

Specify `COMPILE` to cause Oracle Database to recompile the operator.

Examples

Compiling a User-defined Operator: Example

The following example compiles the operator `eq_op` (which was created in "Creating User-Defined Operators: Example"):

```
ALTER OPERATOR eq_op COMPILE;
```

ALTER OUTLINE

Purpose

> **Note:**
>
> Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.
>
> You can migrate existing stored outlines to SQL plan baselines by using the `MIGRATE_STORED_OUTLINE` function of the `DBMS_SPM` package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the `DROP_MIGRATED_STORED_OUTLINE` function of the `DBMS_SPM` package.
>
> See Also: *Oracle Database SQL Tuning Guide* for more information about SQL plan management and *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_SPM` package

Use the `ALTER OUTLINE` statement to rename a stored outline, reassign it to a different category, or regenerate it by compiling the outline's SQL statement and replacing the old outline data with the outline created under current conditions.

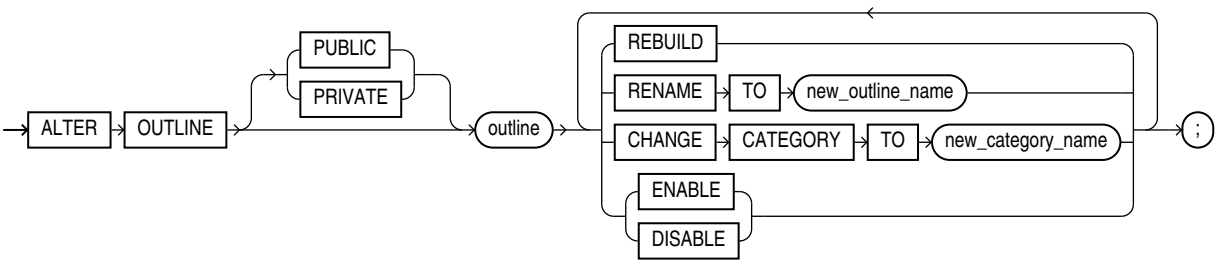
> **See Also:**
>
> CREATE OUTLINE for information on creating an outline

Prerequisites

To modify an outline, you must have the `ALTER ANY OUTLINE` system privilege.

Syntax

***alter_outline*::=**



Semantics

PUBLIC | PRIVATE

Specify `PUBLIC` if you want to modify the public version of this outline. This is the default.

Specify `PRIVATE` if you want to modify an outline that is private to the current session and whose data is stored in the current parsing schema.

outline

Specify the name of the outline to be modified.

REBUILD

Specify `REBUILD` to regenerate the execution plan for *`outline`* using current conditions.

> **See Also:**
>
> "Rebuilding an Outline: Example"

RENAME TO Clause

Use the `RENAME TO` clause to specify an outline name to replace *`outline`*.

CHANGE CATEGORY TO Clause

Use the `CHANGE CATEGORY TO` clause to specify the name of the category into which the *`outline`* will be moved.

ENABLE | DISABLE

Use this clause to selectively enable or disable this outline. Outlines are enabled by default. The `DISABLE` keyword lets you disable one outline without affecting the use of other outlines.

Examples

Rebuilding an Outline: Example

The following statement regenerates a stored outline called `salaries` by compiling the text of the outline and replacing the old outline data with the outline created under current conditions.

```
ALTER OUTLINE salaries REBUILD;
```

ALTER PACKAGE

Purpose

Packages are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `ALTER PACKAGE` statement to explicitly recompile a package specification, body, or both. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

Because all objects in a package are stored as a unit, the `ALTER PACKAGE` statement recompiles all package objects together. You cannot use the `ALTER PROCEDURE` statement or `ALTER FUNCTION` statement to recompile individually a procedure or function that is part of a package.

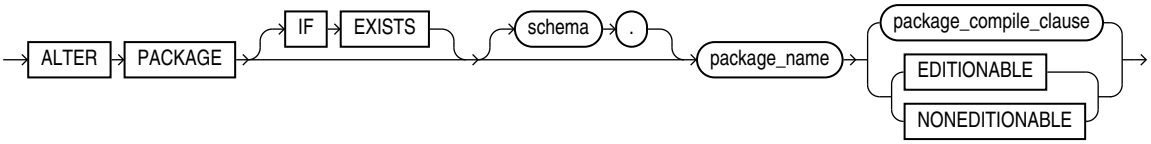
> **Note:**
>
> This statement does not change the declaration or definition of an existing package. To redeclare or redefine a package, use the CREATE PACKAGE or the CREATE PACKAGE BODY statement with the `OR REPLACE` clause.

Prerequisites

For you to modify a package, the package must be in your own schema or you must have `ALTER ANY PROCEDURE` system privilege.

Syntax

***alter_package*::=**



(*package_compile_clause*: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

schema

Specify the schema containing the package. If you omit *schema*, then Oracle Database assumes the package is in your own schema.

package_name

Specify the name of the package to be recompiled.

package_compile_clause

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling packages.

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the package becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `PACKAGE` in *schema*. The default is

EDITIONABLE. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

ALTER PLUGGABLE DATABASE

Purpose

Use the ALTER PLUGGABLE DATABASE statement to modify a pluggable database (PDB). The PDB can be a traditional PDB, an application container, or an application PDB.

This statement enables you to perform the following tasks:

- Unplug a PDB from a multitenant container database (CDB) (using the *pdb_unplug_clause*)
- Modify the settings of a PDB (using the *pdb_settings_clauses*)
- Bring PDB data files online or take them offline (using the *pdb_datafile_clause*)
- Back up and recover a PDB (using the *pdb_recovery_clauses*)
- Modify the state of a PDB (using the *pdb_change_state* clause)
- Modify the state of multiple PDBs within a CDB (using the *pdb_change_state_from_root* clause)
- Perform operations on applications in an application container (using the *application_clauses*)
- Create and manage PDB snapshots using the *snapshot_clauses*

> **Note:**
>
> You can perform all ALTER PLUGGABLE DATABASE tasks by connecting to a PDB and running the corresponding ALTER DATABASE statement. This functionality is provided to maintain backward compatibility for applications that have been migrated to a CDB environment. The exception is modifying PDB storage limits, for which you must use the *pdb_storage_clause* of ALTER PLUGGABLE DATABASE.

> **See Also:**
>
> CREATE PLUGGABLE DATABASE for information on creating PDBs

Prerequisites

You must be connected to a CDB.

To specify the *pdb_unplug_clause*, the current container must be the root or the application root, you must be authenticated AS SYSDBA or AS SYSOPER, and the SYSDBA or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root and locally in the PDB you want to unplug.

To specify the *pdb_settings_clauses*, the current container must be the PDB whose settings you want to modify and you must have the ALTER DATABASE privilege, either granted commonly

or granted locally in the PDB. To specify the *pdb_logging_clauses* or the RENAME GLOBAL_NAME clause, you must also have the RESTRICTED SESSION privilege, either granted commonly or granted locally in the PDB being renamed, and the PDB must be in READ WRITE RESTRICTED mode.

To specify the *pdb_datafile_clause*, the current container must be the PDB whose datafiles you want to bring online or take offline and you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the PDB.

To specify the *pdb_recovery_clauses*, the current container must be the PDB you want to back up or recover and you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the PDB.

To specify the *pdb_change_state* clause, the current container must be the PDB whose state you want to change and you must be authenticated AS SYSBACKUP, AS SYSDBA, AS SYSDG, or AS SYSOPER.

To specify the *pdb_change_state_from_root* clause, the current container must be the root or the application root, you must be authenticated AS SYSBACKUP, AS SYSDBA, AS SYSDG, or AS SYSOPER, and the SYSBACKUP, SYSDBA, SYSDG, or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root or application root, and locally in the PDB(s) whose state(s) you want to change.

To specify the *application_clauses*, the current container must be an application container, you must be authenticated AS SYSBACKUP or AS SYSDBA, and the SYSBACKUP or SYSDBA privilege must be either granted to you commonly, or granted to you locally in the application root and locally in the application PDB(s) in which you want to perform application operations.

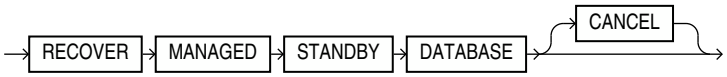
***lost_write_protection* ::=**

The usage for the `lost_write_protection` clause with the `ALTER PLUGGABLE DATABASE` statement is identical to the `ALTER DATABASE` statement. Look here ALTER DATABASE for syntax details.

***pdb_managed_recovery* ::=**



Semantics

database_clause

Specify the `PLUGGABLE DATABASE` option for a container database.

pdb_name

Specify the name of the database to be altered. If you omit *db_name*, then Oracle Database alters the database identified by the value of the initialization parameter `DB_NAME`. You can alter only the database whose control files are specified by the initialization parameter `CONTROL_FILES`. The database identifier is not related to the Oracle Net database specification.

pdb_unplug_clause

This clause lets you unplug a PDB from a CDB. When you unplug a PDB, Oracle stores information about the PDB in a file on your operating system. You can subsequently use this file to plug the PDB into a CDB.

For *pdb_name*, specify the name of the PDB you want to unplug. The PDB must be closed—that is, the open mode must be `MOUNTED`. In an Oracle Real Application Clusters (Oracle RAC) environment, the PDB must be closed in all Oracle RAC instances

For *filename*, specify the full path name of the operating system file in which to store information about the PDB. The file name that you specify determines the type of information stored and how it is stored.

- If you specify a file name that ends with the extension .xml, then Oracle creates an XML file containing metadata about the PDB. You can then copy the XML file and the PDB's data files to a new location and specify the XML file name when plugging the PDB into a CDB. In this case, you must copy the PDB's data files separately.
- If you specify a file name that ends with the extension .pdb, then Oracle creates a .pdb archive file. This is a compressed file that includes an XML file containing metadata about the PDB, as well as the PDB's data files. You can then copy this single archive file to a new location and specify the archive file name when plugging the PDB into a CDB. This eliminates having to copy the PDB's data files separately. When you use a .pdb archive file when plugging in a PDB, this file is extracted when you plug in the PDB, and the PDB’s files are placed in the same directory as the .pdb archive file.

After a PDB is unplugged, it remains in the CDB with an open mode of `MOUNTED` and a status of `UNPLUGGED`. The only operation you can perform on an unplugged PDB is `DROP PLUGGABLE DATABASE`, which will remove it from the CDB. You must drop the PDB before you can plug it into the same CDB or another CDB.

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for more information on unplugging a PDB
> - The *create_pdb_from_xml* clause of `CREATE PLUGGABLE DATABASE` for information on plugging a PDB into a CDB

pdb_unplug_encrypt

You must have the `SYSKM` privilege to execute this command.

United PDBs

- `ENCRYPT USING transport_secret` is optional.
- If TDE is in use, you must specify this clause. If TDE is not in use, the statement throws the following error `ORA-46680:master keys of the container database must be exported.`
- The wallet must be open in `ROOT` if TDE is in use.
- Keys are encrypted using the provided *`transport secret`* and exported into the `.XML` or archive file

Unplugging a PDB Into an XML Metadata File: Example

```
ALTER PLUGGABLE DATABASE CDB1_PDB2 UNPLUG INTO '/tmp/cdb1_pdb2.xml' ENCRYPT USING
transport_secret
```

Unplugging a PDB Into an Archive File: Example

```
ALTER PLUGGABLE DATABASE CDB1_PDB1_1 UNPLUG INTO '/tmp/CDB1_PDB1_1.pdb' ENCRYPT USING
transport_secret
```

For PDBs in **isolated** mode, you need not specify `ENCRYPT USING transport_secret`. This is not required because the wallet file of the PDB is copied during the creation of the pluggable database from an XML file. If you are unplugging a PDB as an archive file, the wallet file of the PDB is added to the zipped archive with the `.pdb` extension.

If the `ewallet.p12` file already exists at the destination, a backup is automatically initiated. The backup file has the following format: `ewallet_PLGDB_2017090517455564.p12`.

pdb_settings_clauses

These clauses lets you modify various settings for a PDB.

pdb_name

You can optionally use *`pdb_name`* to specify the name of the PDB whose settings you want to modify.

DEFAULT EDITION Clause

Use this clause to designate the specified edition as the default edition for the PDB. For the full semantics of this clause, refer to "DEFAULT EDITION Clause" in the `ALTER DATABASE` documentation.

SET DEFAULT TABLESPACE Clause

Use this clause to specify or change the default type of tablespaces subsequently created in the PDB. For the full semantics of this clause, refer to "SET DEFAULT TABLESPACE Clause" in the `ALTER DATABASE` documentation.

DEFAULT TABLESPACE Clause

Use this clause to establish or change the default permanent tablespace of the PDB. For the full semantics of this clause, refer to "DEFAULT TABLESPACE Clause" in the `ALTER DATABASE` documentation.

DEFAULT TEMPORARY TABLESPACE Clause

Use this clause to change the default temporary tablespace of the PDB to a new tablespace or tablespace group. For the full semantics of this clause, refer to "DEFAULT [LOCAL] TEMPORARY TABLESPACE Clause" in the `ALTER DATABASE` documentation.

RENAME GLOBAL_NAME TO Clause

Use this clause to change the global name of the PDB. The new global name must be unique within the CDB. For an Oracle Real Application Clusters (Oracle RAC) database, the PDB must be open in `READ WRITE RESTRICTED` mode on the current instance only. The PDB must be closed on all other instances. For the full semantics of this clause, refer to "RENAME GLOBAL_NAME Clause" in the `ALTER DATABASE` documentation.

> **Note:**
>
> When you change the global name of a PDB, be sure to change the `PLUGGABLE DATABASE` property for database services that are used to connect to the PDB.

set_time_zone_clause

Use this clause to modify the time zone setting for the PDB. For the full semantics of this clause, refer to *set_time_zone_clause* in the `ALTER DATABASE` documentation.

database_file_clauses

Use this clause to modify data files and temp files for the PDB. For the full semantics of this clause, refer to *database_file_clauses* in the `ALTER DATABASE` documentation.

supplemental_db_logging

Use these clauses to instruct Oracle Database to add or stop adding supplemental data into the log stream for the PDB.

- Specify the `ADD SUPPLEMENTAL LOG` clause to add supplemental data into the log stream for the PDB. In order to issue this clause, supplemental logging must have been enabled for the CDB root with the `ALTER DATABASE ... ADD SUPPLEMENTAL LOG ...` statement. The level of supplemental logging that you specify for the PDB does not need to match that of the CDB root. That is, you can specify any of the clauses `DATA`, *`supplemental_id_key_clause`*, or *`supplemental_plsql_clause`* for the PDB, regardless of which clause was specified when enabling supplemental logging for the CDB root.

- Specify the DROP SUPPLEMENTAL LOG clause to stop adding supplemental data into the log stream for the PDB.

ADD SUPPLEMENTAL LOG DATA SUBSET DATABASE REPLICATION, of ALTER PLUGGABLE DATABASE enables low impact minimal supplemental logging on the PDB.

- You can only execute this DDL on a pluggable database.
- You can execute this DDL only when the *enable_goldengate_replication* parameter is TRUE, and database compatible is 19.0 or higher.
- You must enable minimal supplemental logging in CDB$ROOT to run this command.
- After you execute this DDL, minimal supplemental logging will become low impact for the pluggable database. SYS.PROP$ will be updated to indicate that low impact minimal supplemental logging is enabled at the PDB level for this pluggable database.

DROP SUPPLEMENTAL LOG DATA SUBSET DATABASE REPLICATION, of ALTER PLUGGABLE DATABASE disables low impact minimal supplemental logging on the PDB.

- You can only execute this DDL on a pluggable database.
- You can execute this DDL only when the *enable_goldengate_replication* parameter is TRUE, and database compatible is 19.0 or higher.
- You must enable minimal supplemental logging in CDB$ROOT to run this command.
- SYS.PROP$ will be updated to indicate that supplemental logging for subset database replication is disabled at the PDB level for this pluggable database. If supplemental logging for subset database replication is also disabled at CDB$ROOT (CDB level), then low impact minimal supplemental logging will be disabled for this pluggable database.

For the full semantics of this clause, refer to *supplemental_db_logging* in the ALTER DATABASE documentation.

pdb_storage_clause

Use this clause to modify the storage limits for a PDB.

This clause has the same semantics as the *pdb_storage_clause* in the CREATE PLUGGABLE DATABASE documentation, with the following additions:

- If you specify MAXSIZE *size_clause*, then the value you specify for *size_clause* must be greater than or equal to the combined size of the existing tablespaces belonging to the PDB. Otherwise, an error occurs.
- If you specify MAX_AUDIT_SIZE *size_clause*, then the value you specify for *size_clause* must be greater than or equal to the amount of storage used by the existing unified audit OS spillover (.bin format) files in the PDB. Otherwise, an error occurs.
- If you specify MAX_DIAG_SIZE *size_clause*, then the value you specify for *size_clause* must be greater than or equal to the amount of storage for diagnostics in the Automatic Diagnostic Repository (ADR) that is currently used by the PDB. Otherwise an error occurs.

pdb_logging_clauses

Use these clauses to set or change the logging characteristics of the PDB.

logging_clause

Use this clause to change the default logging attribute for tablespaces subsequently created within the PDB. This clause has the same semantics as the *logging_clause* in the CREATE PLUGGABLE DATABASE documentation.

pdb_force_logging_clause

Use this clause to place a PDB into, or take it out of, one of four logging modes.

Force logging mode instructs the database to log all changes in the PDB, except changes in temporary tablespaces and temporary segments. Force nologging mode instructs the database to not log any changes in the PDB.

Standby nologging instructs the database to not log operations that qualify to be done without logging. The database sends the data blocks that were created by the operation to each qualifying standby database in the Data Guard configuration, typically resulting in those standbys not having invalid blocks.

CDB-wide force logging mode takes precedence over any other setting. PDB-level force logging mode and force nologging mode take precedence over and are independent of any `LOGGING`, `NOLOGGING`, or `FORCE LOGGING` settings you specify for individual tablespaces in the PDB and any `LOGGING` or `NOLOGGING` settings you specify for individual database objects in the PDB.

- Specify `ENABLE FORCE LOGGING` to place the PDB in force logging mode. If the PDB is currently in force nologging mode, then specifying this clause results in an error. You must first specify `DISABLE FORCE NOLOGGING`.
- Specify `DISABLE FORCE LOGGING` to take the PDB out of force logging mode. If the PDB is not currently in force logging mode, then specifying this clause results in an error.
- Specify `ENABLE FORCE NOLOGGING` to place the PDB in force nologging mode. If the PDB is currently in force logging mode, then specifying this clause results in an error. You must first specify `DISABLE FORCE LOGGING`. The nonlogged operations will use classic invalidation redo, even if the CDB has a standby nologging mode set.
- Specify `DISABLE FORCE NOLOGGING` to take the PDB out of force nologging mode. If the PDB is not currently in force nologging mode, then specifying this clause results in an error.
- Specify `SET STANDBY NOLOGGING FOR LOAD PERFORMANCE` to put the PDB into standby nologging for load performance mode. In this mode the data loaded as part of the nonlogged task is sent to the qualifying standbys via a private network connection, provided that doing so will not slow down the load process. If a slow down occurs, then the data is not sent but fetched automatically from the primary as each standby encounters the invalidation redo and will be retried until the data blocks are eventually received.
- Specify `SET STANDBY NOLOGGING FOR DATA AVAILABILITY` to put the PDB into standby nologging for data availability mode. In this mode the data loaded as part of the nonlogged task is sent to the qualifying standbys either via a network connection to them, or if that fails, via block images in the redo. That is to say, in this mode the load will switch to be done in a logged fashion if the network connection or related processes prevent the sending of the data over the private network connection.

For the standby nologging modes a qualifying standby is one that is open for read, running managed recovery, and receiving redo into standby redo logs.

This clause does not change the default `LOGGING` or `NOLOGGING` mode of the PDB specified by the *logging_clause*.

pdb_refresh_mode_clause

Use this clause to change the refresh mode of a PDB. You can specify this clause only for a refreshable PDB, that is, a PDB whose current refresh mode is `MANUAL` or `EVERY` *`refresh_interval`* `MINUTES` or `HOURS`. You can switch a PDB from manual refresh to automatic refresh, or from automatic refresh to manual refresh. You can also use this clause to change

the number of minutes between automatic refreshes. You can switch a PDB from manual or automatic refresh to no refresh, but you cannot enable manual or automatic refresh for a PDB that is not refreshable. For the complete semantics of this clause, refer to the *pdb_refresh_mode_clause* in the documentation on `CREATE PLUGGABLE DATABASE`.

REFRESH

Specify this clause to perform a manual refresh of a refreshable PDB, that is, a PDB whose current refresh mode is `MANUAL` or `EVERY` *number* `MINUTES`. The PDB must be closed. For more information on refreshable PDBs, refer to the *pdb_refresh_mode_clause* in the documentation on `CREATE PLUGGABLE DATABASE`.

pdb_refresh_switchover_clause

Use this clause to reverse roles between a refreshable clone PDB and a primary PDB. This clause makes the refreshable clone PDB into a primary PDB, which can be opened in read write mode. The former primary PDB becomes the refreshable clone..

- This command must be executed from the primary PDB .
- `REFRESH MODE NONE` may not be specified when issuing this statement.
- The `dblink` should point to the Root of the CDB where the refreshable clone PDB currently resides.
- After this operation, the current PDB will become the refreshable clone and can only be opened in READ ONLY mode.
- The database link user must exist in the primary PDB, if the refreshable clone exists in a different CDB.

PRIORITY

You can control the order of operations on PDBs by assigning a `PRIORITY` to the PDB. The priority*value* should be a whole number greater than 0 and less than 4099. A value outside this range throws an error.

The following ordering rules apply to manage different kinds of PDBs:

- PDBs are processed in an ascending order of priority. A PDB with a lower priority value will be processed before a PDB with a higher priority value.
- PDBs with the same priority may be processed in any order. However, if App PDBs and the App Root have the same priority or have no priority, App PDBs will still be opened after the App Root.
- PDBs have no priority are considered to be the lowest priority.
- PDB priority for a given PDB is applicable to all RAC instances, i.e priority is NOT specific to a given RAC instance.
- Priority will not be copied from source PDB to target PDB by plug, unplug or refreshable clone.
- App PDBs cannot have a higher priority than App Root.
- App Root clones have the same priority as App Roots, and cannot be explicitly given a PDB priority.
- The priority of `CDB$ROOT` and `PDB$SEED` is determined internally by Oracle RDBMS and is not subject to PDB priority .

Use `PRIORITY NONE` to reset priority settings on the PDB.

SET CONTAINER_MAP

Use this clause to specify the `CONTAINER_MAP` database property for an application container. The current container must be the application root. The *map_object* is of the form *[schema.]table*. For *schema*, specify the schema containing *table*. If you omit *schema*, then the database assumed that the table is in your own schema. For *table*, specify a range-, list-, or hash-partitioned table.

CONTAINERS DEFAULT TARGET

Use this clause to specify the default container for DML statements in an application container. You must be connect to the application root.

- For *container_name*, specify the name of the default container. The default container can be any container in the application container, including the application root or an application PDB. You can specify only one default container.
- If you specify `NONE`, then the default container is the CDB root. This is the default.

When a DML statement is issued in the application root without specifying containers in the `WHERE` clause, the DML statement affects the default container for the application container.

CONTAINERS HOST and PORT

Use the `HOST` and `PORT` clauses if you want to create a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB.

The following statements can be executed within a PDB:

```
ALTER PLUGGABLE DATABASE CONTAINERS HOST='myhost.example.com';

ALTER PLUGGABLE DATABASE CONTAINERS PORT=1599;
```

The following statements can be executed within CDB Root, Application Root, or within a PDB :

```
ALTER PLUGGABLE DATABASE <pdbname> CONTAINERS HOST='myhost.example.com';

ALTER PLUGGABLE DATABASE <pdbname> CONTAINERS PORT=1599;
```

pdbname must meet the following criteria:

- If the statement is executed in Application Root, then *pdbname* has to match the name of Application Root or the name of one of its Application PDBs.
- If the statement is executed in CDB Root, then *pdbname* has to match the name of one of the PDBs in the CDB.
- If the statement is executed in a PDB, then *pdbname* has to match the name of the current PDB.

> **See Also:**
>
> HOST and PORT of `CREATE PLUGGABLE DATABASE` for the full semantics of `HOST` and `PORT`

pdb_datafile_clause

This clause lets you bring data files associated with a PDB online or take them offline. The PDB must be closed when you issue this clause.

- For *pdb_name*, specify the name of the PDB. If the current container is the PDB, then you can omit *pdb_name*.
- The DATAFILE clauses let you specify the data files you want to bring online or take offline. Use *filename* or *filenumber* to identify specific data files by name or by number. You can view data file names and numbers by querying the NAME and FILE# columns of the V$DATAFILE dynamic performance view. Use ALL to specify all datafiles associated with the PDB.
- Specify ONLINE to bring the data files online or OFFLINE to take the data files offline.

pdb_recovery_clauses

Use the *pdb_recovery_clauses* to back up and recover a PDB.

pdb_name

You can optionally use *pdb_name* to specify the name of the PDB you want to back up or recover.

pdb_general_recovery

This clause lets you control media recovery for the PDB or standby database or for specified tablespaces or files. The *pdb_general_recovery* clause has the same semantics as the *general_recovery* clause of ALTER DATABASE. Refer to the *general_recovery* clause of ALTER DATABASE for more information.

BACKUP Clauses

Use these clauses to move all of the data files in the PDB into or out of online backup mode (also called hot backup mode). These clauses have the same semantics in ALTER PLUGGABLE DATABASE and ALTER DATABASE. Refer to the "BACKUP Clauses" of ALTER DATABASE for more information.

RECOVERY Clauses

Use these clauses to enable or disable a PDB for recovery. The PDB must be closed—that is, the open mode must be MOUNTED.

- Specify ENABLE RECOVERY to bring all data files that belong to a PDB online and enable the PDB for recovery.
- Specify DISABLE RECOVERY to take all data files that belong to a PDB offline and disable the PDB for recovery.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information on the RECOVERY clauses

pdb_change_state

This clause enables you to change the state, or open mode, of a PDB. Table 11-2 lists the open modes of a PDB.

- Specify the *pdb_open* clause to change the open mode to READ WRITE, READ ONLY, or MIGRATE.
- Specify the *pdb_close* clause to change the open mode to MOUNTED.

Table 11-2 PDB Open Modes

Open Mode	Description
READ WRITE	A PDB in open read/write mode allows queries and user transactions to proceed and allows users to generate redo logs.
READ ONLY	A PDB in open read-only mode allows queries but does not allow user changes.
MIGRATE	When a PDB is in open migrate mode, you can run database upgrade scripts on the PDB.
MOUNTED	When a PDB is in mounted mode, it behaves like a non-CDB in mounted mode. It does not allow changes to any objects, and it is accessible only to database administrators. It cannot read from or write to data files. Information about the PDB is removed from memory caches. Cold backups of the PDB are possible.

You can view the open mode of a PDB by querying the OPEN_MODE column of the V$PDBS view.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for a complete description of PDB open modes

pdb_name

You can optionally use *pdb_name* to specify the name of the PDB whose open mode you want to change.

pdb_open

This clause lets you change the open mode of a PDB to READ WRITE, READ ONLY, or MIGRATE. When you specify this clause, the PDB must be in MOUNTED mode unless you specify the FORCE keyword.

If you do not specify READ WRITE or READ ONLY, then the default is READ WRITE. The exception is when the PDB belongs to a CDB that is used as a physical standby database, in which case the default is READ ONLY.

READ WRITE

Specify this clause to change the open mode to READ WRITE.

READ ONLY

Specify this clause to change the open mode to READ ONLY.

HYBRID READ ONLY

Specify this clause to open a PDB in `READ ONLY` and `READ WRITE` mode depending on the type of user that connects to it. When a local user connects to the PDB, the PDB operates in `READ ONLY` mode. The PDB operates in `READ WRITE` mode for common users.

[READ WRITE] UPGRADE

Specify this clause to change the open mode to `MIGRATE`. The `READ WRITE` keywords are optional and are provided for semantic clarity.

RESTRICTED

If you specify the optional `RESTRICTED` keyword, then the PDB is accessible only to users with the `RESTRICTED SESSION` privilege in the PDB.

If the PDB is in `READ WRITE` or `READ ONLY` mode, and you specify the `RESTRICTED` and `FORCE` keywords while changing the open mode, then all sessions connected to the PDB that do not have the `RESTRICTED SESSION` privilege in the PDB are terminated, and their transactions are rolled back.

FORCE

Specify this keyword to change the open mode of a PDB from `READ WRITE` to `READ ONLY`, or from `READ ONLY` to `READ WRITE`. The `FORCE` keyword allows users to remain connected to the PDB while the open mode is changed.

When you specify `FORCE` to change the open mode of a PDB from `READ WRITE` to `READ ONLY`, any `READ WRITE` transaction that is open when you change the open mode will not be allowed to perform any more DML operations or to `COMMIT`.

Restriction on FORCE

You cannot specify the `FORCE` keyword if the PDB is currently in `MIGRATE` mode, and you cannot specify the `FORCE` keyword to change a currently open PDB to `MIGRATE` mode.

RESETLOGS

Specify this clause to create a new PDB incarnation and open the PDB in `READ WRITE` mode after point-in-time recovery of the PDB.

> **See Also:**
>
> *Oracle Database Backup and Recovery User's Guide* for more information on performing point-in-time recovery of CDBs and PDBs

instances_clause

In an Oracle Real Application Clusters environment, use this clause to modify the state of the PDB in the specified Oracle RAC instances. If you omit this clause, then the state of the PDB is modified only in the current instance.

- Use *`instance_name`* to specify one or more instance names, in a comma-separated list enclosed in parenthesis. This modifies the state of the PDB only in those instances.
- Specify `ALL` to modify the state of the PDB in all instances.

- Specify `ALL EXCEPT` to modify the state of the PDB in all instances except the specified instances.

If the PDB is already open in one or more instances, then you can open it in additional instances, but it must be opened in the same mode as in the instances in which it is already open.

services_clause

- Use *`service_name`* to specify one or more services, in a comma-separated list enclosed in parenthesis.
- Specify `ALL` to specify all services on the PDB.
- Specify `ALL EXCEPT` to specify all services except the services specifed.

pdb_close

This clause lets you change the open mode of a PDB to `MOUNTED`. When you specify this clause, the PDB must be in `READ WRITE`, `READ ONLY`, or `MIGRATE` mode. This clause is the PDB equivalent of the SQL*Plus `SHUTDOWN` command.

IMMEDIATE

If you specify the optional `IMMEDIATE` keyword, then this clause is the PDB equivalent of the SQL*Plus `SHUTDOWN` command with the immediate mode. Otherwise, the PDB is shut down with the normal mode.

> **See Also:**
>
> *SQL*Plus User's Guide and Reference* for more information on the SQL*Plus `SHUTDOWN` command

ABORT

Specify `ABORT` to forcibly shut down the PDB.

instances_clause

In an Oracle Real Application Clusters environment, use this clause to modify the state of the PDB in the specified Oracle RAC instances. You can close a PDB in some instances and leave it open in others. Refer to the instances_clause for the full semantics of this clause.

relocate_clause

In an Oracle Real Application Clusters environment, use this clause to instruct the database to reopen the PDB on a different Oracle RAC instance.

- Specify `RELOCATE` to reopen the PDB on a different instance that is selected by Oracle Database.
- Specify `RELOCATE TO '`*`instance_name`*`'` to reopen the PDB in the specified instance.
- Specify `NORELOCATE` to close the PDB in the current instance. This is the default.

pdb_save_or_discard_state

Use this clause to instruct the database to save or discard the open mode of the PDB when the CDB restarts.

- If you specify `SAVE`, then the PDB's open mode after the CDB restarts will be identical to its open mode just before the CDB restarted.
- If you specify `DISCARD`, then the PDB's open mode after the CDB restarts will be `MOUNTED`. This is the default.

instances_clause

In an Oracle Real Application Clusters environment, use this clause to instruct the database to save or discard the open mode of the PDB in the specified Oracle RAC instances. If you omit this clause, then the database applies the `SAVE` or `DISCARD` setting only to the PDB in the current instance.

- Use *`instance_name`* to specify one or more instance names, in a comma-separated list enclosed in parenthesis. This applies the `SAVE` or `DISCARD` setting to the PDB only in those instances.
- Specify `ALL` to apply the `SAVE` or `DISCARD` setting to the PDB in all instances.
- Specify `ALL EXCEPT` to apply the `SAVE` or `DISCARD` setting to the PDB in all instances except the specified instances.

pdb_change_state_from_root

This clause enables you to modify the state of one or more PDBs.

- Specify the *`pdb_name`* for one or more PDBs whose state you want to modify.
- Specify `ALL` to modify the state of all PDBs in the CDB.
- Specify `ALL EXCEPT` to modify the state of all PDBs in the CDB except those specified by using *`pdb_name`*.

If a PDB is already in the specified state, then the PDB's state is unchanged and no error is returned. If the state of a PDB cannot be changed, then an error occurs only for that PDB.

application_clauses

Use the `APPLICATION` clauses to:

- Install, patch, upgrade, and uninstall applications
- Register application versions and patch numbers
- Sync operations on applications

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information on administering application containers

Specifying Application Names

Most of the *`application_clauses`* require you to specify an application name. The maximum length of an application name is 30 bytes. The name must satisfy the requirements listed in "Database Object Naming Rules ". The application name must be unique within an application container.

Specifying Application Versions

Several of the *application_clauses* require you to specify an application version. The application version can be up to 30 bytes in length and can contain alphanumeric characters, punctuations marks, and spaces. The application version is case-sensitive and must be enclosed in single quotation marks.

Specifying Comments

Several of the *application_clauses* allow you to specify a comment to associate with an application install, patch, or upgrade operation. For *comment*, enter a character string enclosed in single quotation marks.

INSTALL Clauses

Use the INSTALL clauses when installing an application in an application container. The current container must be the application root, not an application PDB.

- Specify the BEGIN INSTALL clause before you start installing the application.
  - Use *app_name* to assign a name to the application.
  - Use *app_version* to assign a version to the application.
  - The optional COMMENT clause allows you to enter a comment to be associated with the application version created by this installation.
- Specify the END INSTALL clause after you have finished installing the application.
  - You must specify the same *app_name* that you specified for the corresponding BEGIN INSTALL clause.
  - You need not specify *app_version*, but if you do, then you must specify the same version that you specified for the corresponding BEGIN INSTALL clause.

PATCH Clauses

Use the PATCH clauses when patching an application in an application container. The current container must be the application root, not an application PDB.

- Specify the BEGIN PATCH clause before you start patching the application.
  - For *app_name*, specify the name of the application you want to patch.
  - For *number*, specify the patch number.
  - The optional MINIMUM VERSION clause allows you to specify the minimum version at which the application must be before the patch can be applied. For *app_version*, specify the minimum application version. If the current application version is lower than the minimum application version, then an error occurs. If you omit this clause, then the minimum version is the current application version.
  - The optional COMMENT clause allows you to enter a comment to be associated with the patch.
- Specify the END PATCH clause after you finish patching the application.
  - You must specify the same *app_name* that you specified for the corresponding BEGIN PATCH clause.
  - You need not specify *number*, but if you do, then you must specify the same value that you specified for the corresponding BEGIN PATCH clause.

UPGRADE Clauses

Use the UPGRADE clauses when upgrading an application in an application container. The current container must be the application root, not an application PDB.

If the application root is using TDE, then you must configure an external store before upgrading the application.

- Specify the `BEGIN UPGRADE` clause before you start upgrading the application.
  - For *app_name*, specify the name of the application you want to upgrade.
  - For *start_app_version*, specify the version from which you are upgrading the application. If this version does not match the current application version, then an error occurs.
  - For *end_app_version*, specify the version to which you are upgrading the application.
  - The optional `COMMENT` clause allows you to enter a comment to be associated with the upgrade.
- Specify the `END UPGRADE` clause after you finish upgrading the application.
  - You must specify the same *app_name* that you specified for the corresponding `BEGIN UPGRADE` clause.
  - You need not specify `TO` *end_app_version*, but if you do, then you must specify the same version that you specified for the corresponding `BEGIN UPGRADE` clause.

UNINSTALL Clauses

Use the `UNINSTALL` clauses when uninstalling an application from an application container. The current container must be the application root, not an application PDB.

- Specify the `BEGIN UNINSTALL` clause before you start uninstalling the application.
  - For *app_name*, specify the name of the application you want to uninstall.
- Specify the `END UNINSTALL` clause after you have finished uninstalling the application.
  - You must specify the same *app_name* that you specified for the corresponding `BEGIN UNINSTALL` clause.

SET PATCH

Use the `SET PATCH` clause to register the patch number of an application that is already installed in an application container. This clause allows you to assign a patch number to an application that was not patched using the `PATCH` clauses. This is useful if the application was migrated from a PDB in an earlier Oracle Database release, when the `PATCH` clauses were not available. The current container can be the application root or an application PDB.

- For *app_name*, specify the name of an existing application.
- Use *number* to assign a patch number to the existing application.

SET VERSION

Use the `SET VERSION` clause to register the version of an application that is already installed in an application container. This clause allows you to assign a name and a version to an application that was not installed using the `INSTALL` clauses. This is useful if the application was migrated from a PDB in an earlier Oracle Database release, when the `INSTALL` clauses were not available. The current container can be the application root or an application PDB.

- Use *app_name* to assign a name to the existing application.
- Use *app_version* to assign a version to the existing application.

SET COMPATIBILITY VERSION

Use the `SET COMPATIBILITY VERSION` clause to set the compatibility version for an application.

The compatibility version of an application is the earliest version of the application possible for the application PDBs that belong to the application container. The current container must be the application root, not an application PDB.

> **Note:**
>
> You cannot plug in an application PDB that uses an application version earlier than the compatibility setting of the application container.

- Use *app_name* to specify the name of the application.
- Use *app_version* to specify the compatibility version for the application.
- If you specify CURRENT, then the compatibility version is set to the version of the application in the application root.

The compatibility version is enforced when the compatibility version is set and when an application PDB is created. If there are application root clones that resulted from application upgrades, then all application root clones that correspond to versions earlier than the compatibility version are implicitly dropped.

SYNC TO

You can synchronize an application to a particular version or a patch number. There are two variations:

1. SYNC TO *version_string*
2. SYNC TO PATCH *patch_number*

Example

Assume that you perform the following operations on application salesapp :

1. Install version 1.0
2. Patch 101
3. Upgrade to version 2.0
4. Patch 102
5. Upgrade to 3.0

ALTER PLUGGABLE DATABASE APPLICATION salesapp SYNC TO 2.0 replays all statements up to and including ' Upgrade to version 2.0'.

ALTER PLUGGABLE DATABASE APPLICATION salesapp SYNC TO PATCH 102 replays all statements up to and including ' Patch 102'.

Restrictions on SYNC TO

You can use SYNC TO only with an individual application.

You cannot use SYNC TO with the ALL SYNC clause.

You cannot use SYNC TO with the SYNC clause, in the case when you are synchronizing multiple applications in a single statement.

SYNC

Use the `SYNC` clause to synchronize an application in an application PDB to the version and patch level of the same application in the application root. The current container must be an application PDB.

app_name specifies the name of an application that exists in the application root. The application may or may not exist in the application PDB.

Starting with Oracle Database Release 21c you can synchronize mutiple applications in one statement with `SYNC` . This is necessary to preserve functional correctness for applications that depend on one another.

Example

```
ALTER PLUGGABLE DATABASE APPLICATION hrapp payrollapp employeesapp SYNC
```

Restrictions on Synchronizing Multiple Applications Using SYNC

- You cannot use the `SYNC TO` *version_string* clause while synchronizing multiple applications with `SYNC`.
- You cannot use the `SYNC TO PATCH` *patch_number* clause while synchronizing multiple applications with `SYNC`.

ALL SYNC

Use the `ALL SYNC` clause to sync all applications in an application PDB with all applications in the application root. This clause is useful, if you have recently added the application PDB to the CDB and would like to sync its applications with the CDB. The current container must be an application PDB.

With Release 21c you can use `EXCEPT` to exclude applications from `ALL SYNC`.

Example

```
ALTER PLUGGABLE DATABASE APPLICATION ALL EXCEPT hrapp payrollapp SYNC
```

Restrictions on Excluding Multiple Applications Using ALL SYNC

- You cannot use the `SYNC TO` *version_string* clause while excluding multiple applications with `ALL EXCEPT SYNC`.
- You cannot use the `SYNC TO PATCH` *patch_number* clause while excluding multiple applications with `ALL EXCEPT SYNC`.

snapshot_clauses

The snapshot clauses allow you to create and manage snapshots of the PDB for the lifetime of the PDB.

pdb_snapshot_clause

Specify this clause to enable the creation of PDB snapshots. You can also specify this clause in the `CREATE PLUGGABLE DATABASE` statement.

- `NONE` is the default and means that no snapshots of the PDB can be created.
- `MANUAL` means that a snapshot of the PDB can be created only manually.

- If `snapshot_interval` is specified, PDB snapshots will be created automatically at the interval specified. In addition, a user will also be able to create PDB snapshots manually.
- If expressed in minutes, the `snapshot_interval` must be less than 3000.
- If expressed in hours, the `snapshot_interval` must be less than 2000.

materialize_clause

Use this clause to convert a snapshot PDB into a full PDB clone. You can delete and purge a PDB snapshot using the clause in this way.

- This clause can only be specified for PDBs created as a snapshot.
- All blocks in all datafiles belonging to the PDB will be copied.

create_snapshot_clause

Use this clause to manually create a PDB snapshot after connecting to the PDB.

- This statement may be issued even if the PDB was set to have PDB snapshots created automatically.
- If a PDB Snapshot with the specified name already exists, an error will be reported.
- A PDB Snapshot with specified name will be created.

drop_snapshot_clause

Use this clause to manually drop a PDB snapshot after connecting to the PDB.

- If this snapshot is being used by some PDB, an error will be reported.

set_max_pdb_snapshots

Use this clause to increase or decrease the maximum number of snapshots for a given PDB. You must first connect to the PDB.

- If the PDB is not open in read/write mode when issuing the statement, an error is raised.
- You can drop all PDB snapshots by setting the the max number to 0.
- The maximum number of snapshots that you can set per PDB is 8.

prepare_clause

- Use this clause to prepare mirror copies of the database. You must provide a *`mirror_name`* to identify the filegroup that is created. The created filegroup contains all the prepared files.
- Specify the number of copies to be prepared by the `REDUNDANCY` options: `EXTERNAL`, `NORMAL`, or `HIGH`.
- If you do not specify the redundancy of the mirror, the redundancy of the source database is used.
- Use the `FOR DATABASE` clause to specify the new name of the CDB. This name should be unique. It will be used in the *`create_pdb_from_mirror_copy`* clause of the `CREATE PLUGGABLE DATABASE` statement.

Prepare a Pluggable Database By Name: Example

If you specify the name (*`pdb_name`*) of the pluggable database, it checks if *`pdb_name`* matches with the current PDB. If it matches, it runs.

```
ALTER PLUGGABLE DATABASE pdb_name PREPARE MIRROR COPY mirror_name WITH HIGH REDUNDANCY
```

Prepare a Pluggable Database Without a Name: Example

If you do not specify the name (*pdb_name*) of the pluggable database, the statement runs on the current PDB.

```
ALTER PLUGGABLE DATABASE PREPARE MIRROR COPY mirror_name WITH HIGH REDUNDANCY
```

drop_mirror_copy

Use this clause to discard mirror copies of data and metadata created by the prepare statement. You must specify the same mirror name that you used for the prepare operation.

You cannot use this clause to drop a database that has already been split by the `CREATE DATABASE` or `CREATE PLUGGABLE DATABASE` statement.

lost_write_protection

Turn on Lost Write for a Pluggable Database : Example

```
ALTER PLUGGABLE DATABASE
  ENABLE LOST WRITE PROTECTION
```

Turn off Lost Write for a Pluggable Database : Example

```
ALTER PLUGGABLE DATABASE
  DISABLE LOST WRITE PROTECTION
```

Note that disabling lost write for the database does not deallocate the lost write storage. You must use the `DROP TABLESPACE` statement to deallocate lost write storage.

pdb_managed_recovery

Specify this clause to recover a PDB in instances where the PDB is within a physical standby CDB.

ENABLE | DISABLE BACKUP

PDB backup is enabled by default. To exclude the PDB from the backup, you can specify disable.

Examples

Unplugging a PDB from a CDB: Example

The following statement unplugs PDB `pdb1` and stores metadata for the PDB into XML file `/oracle/data/pdb1.xml`:

```
ALTER PLUGGABLE DATABASE pdb1
  UNPLUG INTO '/oracle/data/pdb1.xml';
```

Modifying the Settings of a PDB: Example

The following statement changes the limit for the amount of storage used by all tablespaces in PDB `pdb2` to 500M:

```
ALTER PLUGGABLE DATABASE pdb2
  STORAGE (MAXSIZE 500M);
```

Taking the Data Files of a PDB Offline: Example

The following statement takes the data files associated with PDB `pdb3` offline:

```
ALTER PLUGGABLE DATABASE pdb3
  DATAFILE ALL OFFLINE;
```

Changing the State of a PDB: Examples

Assume that PDB pdb4 is closed—that is, its open mode is MOUNTED. The following statement opens pdb4 with open mode READ ONLY:

```
ALTER PLUGGABLE DATABASE pdb4
  OPEN READ ONLY;
```

The following statement uses the FORCE keyword to change the open mode of pdb4 from READ ONLY to READ WRITE:

```
ALTER PLUGGABLE DATABASE pdb4
  OPEN READ WRITE FORCE;
```

The following statement closes PDB pdb4:

```
ALTER PLUGGABLE DATABASE pdb4
  CLOSE;
```

The following statement opens PDB pdb4 with open mode READ ONLY. Because the RESTRICTED keyword is specified, the PDB is accessible only to users with the RESTRICTED SESSION privilege in the PDB.

```
ALTER PLUGGABLE DATABASE pdb4
  OPEN READ ONLY RESTRICTED;
```

Assume that PDB pdb5 is closed—that is, its open mode is MOUNTED. In an Oracle Real Application Clusters environment, the following statement opens PDB pdb5 with open mode READ WRITE in instances ORCLDB_1 and ORCLDB_2:

```
ALTER PLUGGABLE DATABASE pdb5
  OPEN READ WRITE INSTANCES = ('ORCLDB_1', 'ORCLDB_2');
```

In an Oracle Real Application Clusters environment, the following statement closes PDB pdb6 in the current instance and instructs the database to reopen pdb6 in instance ORCLDB_3:

```
ALTER PLUGGABLE DATABASE pdb6
  CLOSE RELOCATE TO 'ORCLDB_3';
```

Changing the State of All PDBs in a CDB: Example

Assume that the current container is the root. The following statement opens all PDBs in the CDB with open mode READ ONLY:

```
ALTER PLUGGABLE DATABASE ALL
  OPEN READ ONLY;
```

ALTER PMEM FILESTORE

Purpose

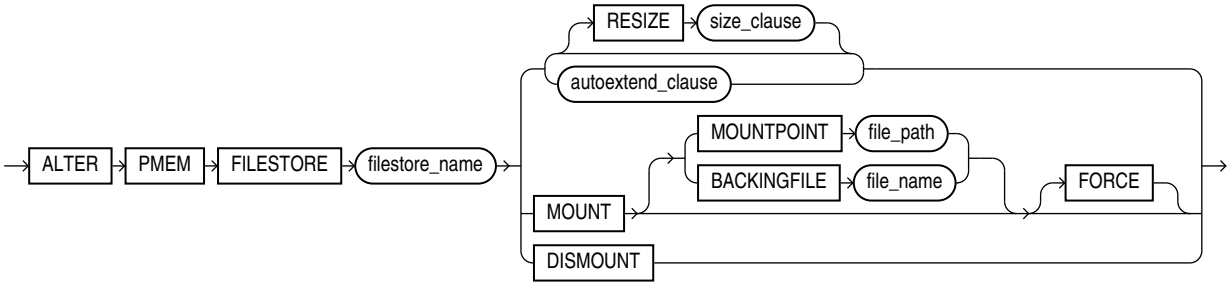
Use this command to change the attributes of a PMEM file store.

Prerequisites

You cannot change the block size of a PMEM file store.

Syntax

alter_pmem_filestore



Semantics

MOUNT

Use this command to mount a PMEM file store. If you have already specified the mount point and backing file paths in the `init.ora` file you can issue the command like this:

```
ALTER PMEM FILESTORE 'filestore_name' MOUNT
```

You can also specify the mount point and backing file paths in the command line. In this case, you must ensure that there is no mismatch between the values in the `init.ora` file and the values you specify in the command line. The command fails when a mismatch occurs, unless you specify `FORCE` to override the values in the `init.ora` file. The paths on the command line become the new paths for the PMEM file store.

If you use a `spfile`, then the parameters are automatically updated with the new paths specified on the command line.

Use the mount PMEM file store command in cases when the PMEM file store was not already automatically mounted during database startup.

Specify the mount point path or the backing file path on the command line when:

- You have not specified either the mount point path or the backing file path in the `init.ora` file
- You want to specify new values for either the mount point path or the backing file path

Before you can change the mount point and the backing file, you must first dismount the file store.

DISMOUNT

Use this command to dismount a PMEM file store. You must ensure that the database instance is in `NOMOUNT` mode.

Examples

Example 1: Resize File Store Named cloud_db_1

```
ALTER PMEM FILESTORE cloud_db_1 RESIZE 5T
```

Example 2: Mount File Store Named cloud_db_1

```
ALTER  PMEM FILESTORE cloud_db_1 MOUNT  MOUNTPOINT '/corp/db/cloud_db_1'
    BACKINGFILE '/var/pmem/foo_1'
```

Example 3: Dismount File Store Named cloud_db_1

```
ALTER PMEM FILESTORE cloud_db_1 DISMOUNT
```

ALTER PROCEDURE

Purpose

Packages are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `ALTER PROCEDURE` statement to explicitly recompile a standalone stored procedure. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

To recompile a procedure that is part of a package, recompile the entire package using the `ALTER PACKAGE` statement (see ALTER PACKAGE).

> **Note:**
>
> This statement does not change the declaration or definition of an existing procedure. To redeclare or redefine a procedure, use the `CREATE PROCEDURE` statement with the `OR REPLACE` clause (see CREATE PROCEDURE).

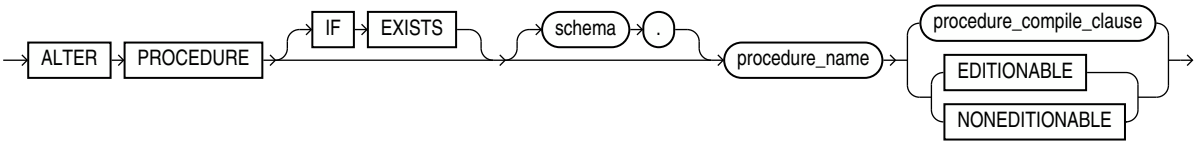
The `ALTER PROCEDURE` statement is quite similar to the `ALTER FUNCTION` statement. Refer to ALTER FUNCTION for more information.

Prerequisites

The procedure must be in your own schema or you must have `ALTER ANY PROCEDURE` system privilege.

Syntax

***alter_procedure*::=**



(*procedure_compile_clause*: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

schema

Specify the schema containing the procedure. If you omit *`schema`*, then Oracle Database assumes the procedure is in your own schema.

procedure_name

Specify the name of the procedure to be recompiled.

procedure_compile_clause

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling procedures.

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the procedure becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `PROCEDURE` in *`schema`*. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

ALTER PROFILE

Purpose

Use the `ALTER PROFILE` statement to add, modify, or remove a resource limit or password management parameter in a profile.

Changes made to a profile with an `ALTER PROFILE` statement affect users only in their subsequent sessions, not in their current sessions.

> **See Also:**
>
> CREATE PROFILE for information on creating a profile

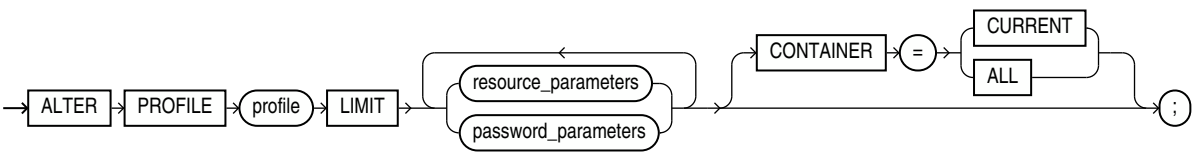
Prerequisites

You must have the `ALTER PROFILE` system privilege.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

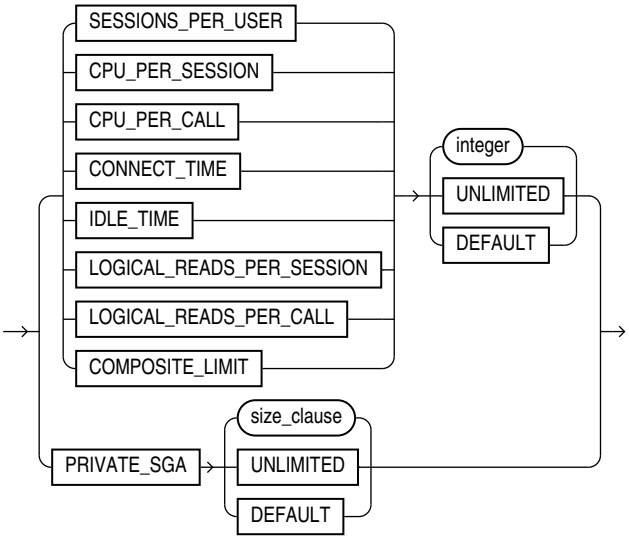
Syntax

***alter_profile*::=**



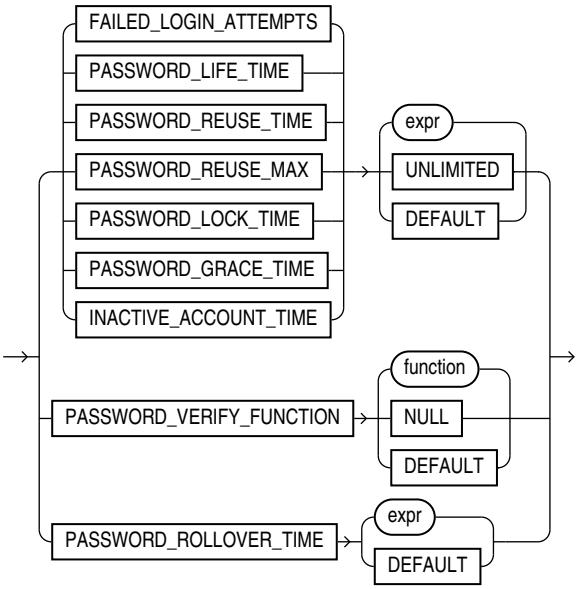
(*resource_parameters*::=, *password_parameters*::=)

***resource_parameters*::=**



(*size_clause*::=)

***password_parameters*::=**



Semantics

The keywords, parameters, and clauses common to `ALTER PROFILE` and `CREATE PROFILE` have the same meaning. For full semantics of these keywords, parameters, and clauses refer to CREATE PROFILE .

Only common users who have been commonly granted the `ALTER PROFILE` system privilege can alter or drop the mandatory profile, and only from the CDB root.

You cannot remove a limit from the `DEFAULT` profile.

Examples

Making a Password Unavailable: Example

The following statement makes the password of the `new_profile` profile (created in "Creating a Profile: Example") unavailable for reuse for 90 days:

```
ALTER PROFILE new_profile
   LIMIT PASSWORD_REUSE_TIME 90
   PASSWORD_REUSE_MAX UNLIMITED;
```

Setting Default Password Values: Example

The following statement defaults the `PASSWORD_REUSE_TIME` value of the `app_user` profile (created in "Setting Profile Resource Limits: Example") to its defined value in the `DEFAULT` profile:

```
ALTER PROFILE app_user
   LIMIT PASSWORD_REUSE_TIME DEFAULT
   PASSWORD_REUSE_MAX UNLIMITED;
```

Limiting Login Attempts and Password Lock Time: Example

The following statement alters profile `app_user` with `FAILED_LOGIN_ATTEMPTS` set to 5 and `PASSWORD_LOCK_TIME` set to 1:

```
ALTER PROFILE app_user LIMIT
   FAILED_LOGIN_ATTEMPTS 5
   PASSWORD_LOCK_TIME 1;
```

This statement causes any user account to which the `app_user` profile is assigned to become locked for one day after five consecutive unsuccessful login attempts.

Changing Password Lifetime and Grace Period: Example

The following statement modifies the profile `app_user2 PASSWORD_LIFE_TIME` to 90 days and `PASSWORD_GRACE_TIME` to 5 days:

```
ALTER PROFILE app_user2 LIMIT
   PASSWORD_LIFE_TIME 90
   PASSWORD_GRACE_TIME 5;
```

Limiting Account Inactivity: Example

The following statement modifies the profile `app_user2 INACTIVE_ACCOUNT_TIME` to 30 consecutive days:

```
ALTER PROFILE app_user2 LIMIT
  INACTIVE_ACCOUNT_TIME 30;
```

If the account has already been inactive for a certain number of days, then those days count toward the new 30 day limit.

Limiting Concurrent Sessions: Example

This statement defines a new limit of 5 concurrent sessions for the `app_user` profile:

```
ALTER PROFILE app_user LIMIT SESSIONS_PER_USER 5;
```

If the `app_user` profile does not currently define a limit for `SESSIONS_PER_USER`, then the preceding statement adds the limit of 5 to the profile. If the profile already defines a limit, then the preceding statement redefines it to 5. Any user assigned the `app_user` profile is subsequently limited to 5 concurrent sessions.

Removing Profile Limits: Example

This statement removes the `IDLE_TIME` limit from the `app_user` profile:

```
ALTER PROFILE app_user LIMIT IDLE_TIME DEFAULT;
```

Any user assigned the `app_user` profile is subject in their subsequent sessions to the `IDLE_TIME` limit defined in the `DEFAULT` profile.

Limiting Profile Idle Time: Example

This statement defines a limit of 2 minutes of idle time for the `DEFAULT` profile:

```
ALTER PROFILE default LIMIT IDLE_TIME  2;
```

This `IDLE_TIME` limit applies to these users:

- Users who are not explicitly assigned any profile
- Users who are explicitly assigned a profile that does not define an `IDLE_TIME` limit

This statement defines unlimited idle time for the `app_user2` profile:

```
ALTER PROFILE app_user2 LIMIT IDLE_TIME UNLIMITED;
```

Any user assigned the `app_user2` profile is subsequently permitted unlimited idle time.

Enable Gradual Password Rollover: Example

This statement sets the password rollover time to 2 days in the profile `usr_prof`:

```
ALTER PROFILE usr_prof LIMIT PASSWORD_ROLLOVER_TIME 2 ;
```

ALTER PROPERTY GRAPH

Purpose

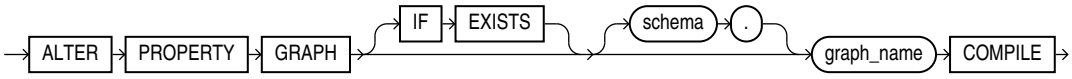
Changes to the underlying objects of the property graph may cause the property graph to be in an invalid state.You can revalidate a graph with `ALTER PROPERTY GRAPH COMPILE`.

Prerequistes

To alter a property graph in any schema except `SYS` and `AUDSYS`, you must have the `ALTER ANY PROPERTY GRAPH` privilege.

Syntax

***alter_property_graph*::=**



Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing property graph.

If you specify `IF NOT EXISTS` with `ALTER`, the command fails with the error message: `Incorrect IF EXISTS clause for ALTER/DROP statement.`

COMPILE

Use `ALTER PROPERTY GRAPH COMPILE` to revalidate a graph that reports an invalid state even though it is actually valid. This happens because the dependencies of the graph to its underlying objects may be too coarse. In such cases, it may be enough to use `ALTER PROPERTY GRAPH COMPILE` to revalidate the property graph.

Example: How a Valid Graph May Falsely Report an Invalid State

```
SQL> create table tbl1(c1 number primary key, c2 number, c3 number, c4 as (c2/
c3), c5 as (1 / (c2+c3)));

Table created.

SQL> create property graph g vertex tables(tbl1 properties(c2, c3, c5));

Property graph created.

SQL> select object_name, object_type, status from user_objects where
object_type in ('PROPERTY GRAPH', 'TABLE');

OBJECT_NAME OBJECT_TYPE STATUS
------------------- ---------------------- -------
G PROPERTY GRAPH VALID
TBL1 TABLE VALID

SQL> alter table tbl1 drop column c4;

Table altered.

SQL> select object_name, object_type, status from user_objects where
object_type in ('PROPERTY GRAPH', 'TABLE');

OBJECT_NAME OBJECT_TYPE STATUS
------------------- ---------------------- -------
G PROPERTY GRAPH INVALID
TBL1 TABLE VALID
```

```
SQL> alter property graph g compile;

Property graph altered.

SQL> select object_name, object_type, status from user_objects where
object_type in ('PROPERTY GRAPH', 'TABLE');

OBJECT_NAME OBJECT_TYPE STATUS
------------------- ---------------------- -------
G PROPERTY GRAPH VALID
TBL1 TABLE VALID

SQL>
```

If `ALTER PROPERTY GRAPH COMPILE` fails to revalidate the graph, then the graph enters the error state. You must then redefine the graph with `CREATE OR REPLACE PROPERTY GRAPH` .

ALTER RESOURCE COST

Purpose

Use the `ALTER RESOURCE COST` statement to specify or change the formula by which Oracle Database calculates the total resource cost used in a session.

Although Oracle Database monitors the use of other resources, only the four resources shown in the syntax can contribute to the total resource cost for a session.

This statement lets you apply weights to the four resources. Oracle Database then applies the weights to the value of these resources that were specified for a profile to establish a formula for calculating total resource cost. You can limit this cost for a session with the `COMPOSITE_LIMIT` parameter of the `CREATE PROFILE` statement. If the resource cost of a session exceeds the limit, then Oracle Database aborts the session and returns an error. If you use the `ALTER RESOURCE COST` statement to change the weight assigned to each resource, then Oracle Database uses these new weights to calculate the total resource cost for all current and subsequent sessions.

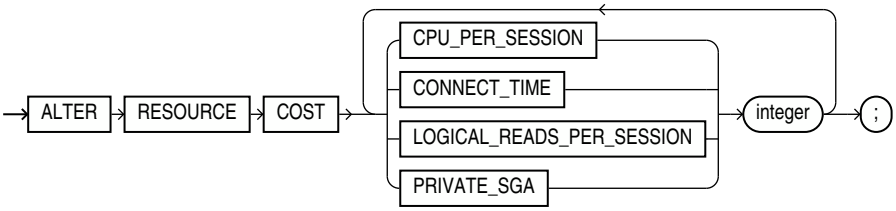
> **See Also:**
>
> CREATE PROFILE for information on all resources and on establishing resource limits

Prerequisites

You must have the `ALTER RESOURCE COST` system privilege.

Syntax

***alter_resource_cost*::=**



Semantics

Oracle Database calculates the total resource cost by first multiplying the amount of each resource used in the session by the weight of the resource, and then summing the products for all four resources. For any session, this cost is limited by the value of the `COMPOSITE_LIMIT` parameter in the user's profile. Both the products and the total cost are expressed in units called **service units**.

CPU_PER_SESSION

Use this keyword to apply a weight to the `CPU_PER_SESSION` resource.

CONNECT_TIME

Use this keyword to apply a weight to the `CONNECT_TIME` resource.

LOGICAL_READS_PER_SESSION

Use this clause to apply a weight to the `LOGICAL_READS_PER_SESSION` resource. Logical reads include blocks read from both memory and disk.

PRIVATE_SGA

Use this clause to apply a weight to the `PRIVATE_SGA` resource. This limit applies only if you are using shared server architecture and allocating private space in the SGA for your session.

integer

Specify the weight of each resource. The weight that you assign to each resource determines how much the use of that resource contributes to the total resource cost. If you do not assign a weight to a resource, then the weight defaults to 0, and use of the resource subsequently does not contribute to the cost. The weights you assign apply to all subsequent sessions in the database.

Examples

Altering Resource Costs: Examples

The following statement assigns weights to the resources `CPU_PER_SESSION` and `CONNECT_TIME`:

```
ALTER RESOURCE COST
   CPU_PER_SESSION 100
   CONNECT_TIME      1;
```

The weights establish this cost formula for a session:

```
cost = (100 * CPU_PER_SESSION) + (1 * CONNECT_TIME)
```

In this example, the values of `CPU_PER_SESSION` and `CONNECT_TIME` are either values in the `DEFAULT` profile or in the profile of the user of the session.

Because the preceding statement assigns no weight to the resources `LOGICAL_READS_PER_SESSION` and `PRIVATE_SGA`, these resources do not appear in the formula.

If a user is assigned a profile with a `COMPOSITE_LIMIT` value of 500, then a session exceeds this limit whenever `cost` exceeds 500. For example, a session using 0.04 seconds of CPU time and 101 minutes of elapsed time exceeds the limit. A session using 0.0301 seconds of CPU time and 200 minutes of elapsed time also exceeds the limit.

You can subsequently change the weights with another `ALTER RESOURCE` statement:

```
ALTER RESOURCE COST
   LOGICAL_READS_PER_SESSION 2
   CONNECT_TIME 0;
```

These new weights establish a new cost formula:

```
cost = (100 * CPU_PER_SESSION) + (2 * LOGICAL_READ_PER_SECOND)
```

where the values of `CPU_PER_SESSION` and `LOGICAL_READS_PER_SECOND` are either the values in the `DEFAULT` profile or in the profile of the user of this session.

This `ALTER RESOURCE COST` statement changes the formula in these ways:

- The statement omits a weight for the `CPU_PER_SESSION` resource. That resource was already assigned a weight, so the resource remains in the formula with its original weight.
- The statement assigns a weight to the `LOGICAL_READS_PER_SESSION` resource, so this resource now appears in the formula.
- The statement assigns a weight of 0 to the `CONNECT_TIME` resource, so this resource no longer appears in the formula.
- The statement omits a weight for the `PRIVATE_SGA` resource. That resource was not already assigned a weight, so the resource still does not appear in the formula.

ALTER ROLE

Purpose

Use the `ALTER ROLE` statement to change the authorization needed to enable a role.

> **See Also:**
>
> - CREATE ROLE for information on creating a role
> - SET ROLE for information on enabling or disabling a role for your session

Prerequisites

You must either have been granted the role with the `ADMIN OPTION` or have `ALTER ANY ROLE` system privilege.

Before you alter a role to `IDENTIFIED GLOBALLY`, you must:

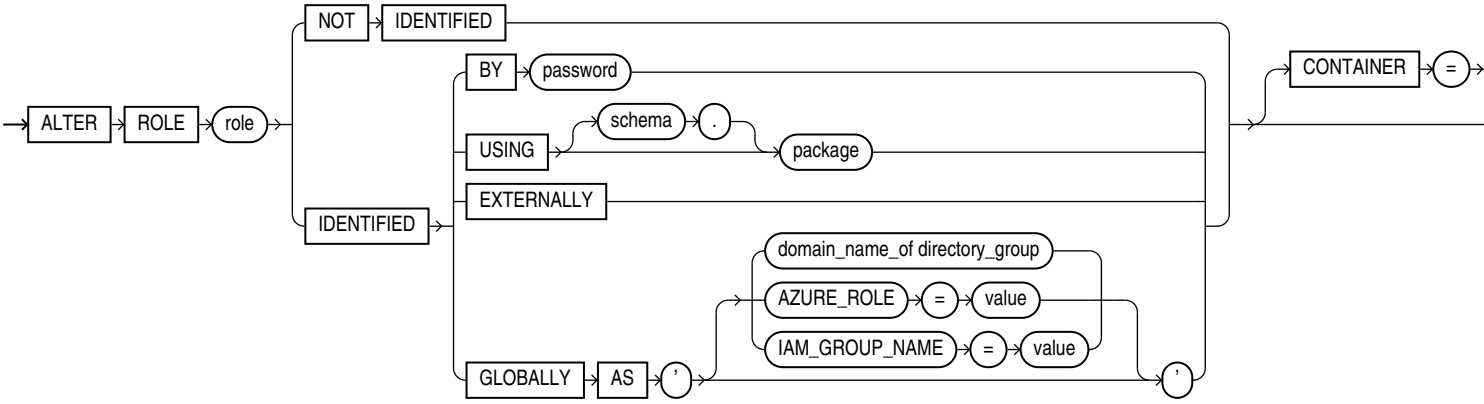
- Revoke all grants of roles identified externally to the role and
- Revoke the grant of the role from all users, roles, and `PUBLIC`.

The one exception to this rule is that you should not revoke the role from the user who is currently altering the role.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

Syntax

***alter_role*::=**



Semantics

The keywords, parameters, and clauses in the `ALTER ROLE` statement all have the same meaning as in the `CREATE ROLE` statement.

Specify `GLOBALLY` with `AS` to map a directory group to a global role when using centrally managed users. The directory group is identified by its domain name.

Restriction on Altering a Role

You cannot alter a `NOT IDENTIFIED` role to any of the `IDENTIFIED` types if it is granted to another role.

Notes on Altering a Role:

- User sessions in which the role is already enabled are not affected.
- If you change a role identified by password to an application role (with the `USING` *`package`* clause), then password information associated with the role is lost. Oracle Database will use the new authentication mechanism the next time the role is to be enabled.
- If you have the `ALTER ANY ROLE` system privilege and you change a role that is `IDENTIFIED GLOBALLY` to `IDENTIFIED BY` *`password`*, `IDENTIFIED EXTERNALLY`, or `NOT IDENTIFIED`, then Oracle Database grants you the altered role with the `ADMIN OPTION`, as it would have if you had created the role identified nonglobally.

For more information, refer to CREATE ROLE and to the examples that follow.

Examples

Changing Role Identification: Example

The following statement changes the role `warehouse_user` (created in "Creating a Role: Example") to `NOT IDENTIFIED`:

```
ALTER ROLE warehouse_user NOT IDENTIFIED;
```

Changing a Role Password: Example

This statement changes the password on the `dw_manager` role (created in "Creating a Role: Example") to `data`:

```
ALTER ROLE dw_manager
   IDENTIFIED BY data;
```

Users granted the `dw_manager` role must subsequently use the new password `data` to enable the role.

Application Roles: Example

The following example changes the `dw_manager` role to an application role using the `hr.admin` package:

```
ALTER ROLE dw_manager IDENTIFIED USING hr.admin;
```

ALTER ROLLBACK SEGMENT

> **Note:**
>
> Oracle strongly recommends that you run your database in automatic undo management mode instead of using rollback segments. Do not use rollback segments unless you must do so for compatibility with earlier versions of Oracle Database. Refer to *Oracle Database Administrator's Guide* for information on automatic undo management.

Purpose

Use the `ALTER ROLLBACK SEGMENT` statement to bring a rollback segment online or offline, change its storage characteristics, or shrink it to an optimal or specified size.

This section assumes that your database is running in rollback undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `MANUAL` or not set at all). If your database is running in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `AUTO`, which is the default), then user-created rollback segments are irrelevant.

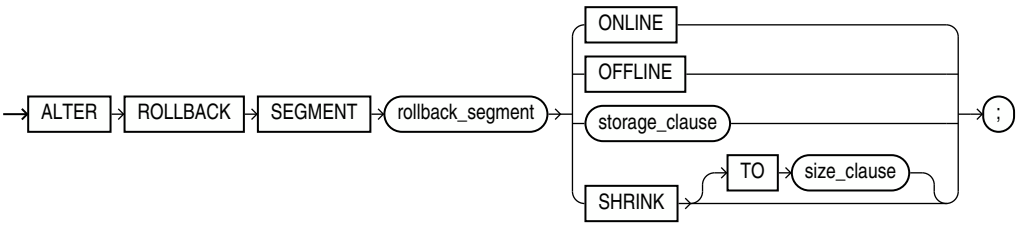
> **See Also:**
>
> - CREATE ROLLBACK SEGMENT for information on creating a rollback segment
> - *Oracle Database Reference* for information on the `UNDO_MANAGEMENT` parameter

Prerequisites

You must have the `ALTER ROLLBACK SEGMENT` system privilege.

Syntax

***alter_rollback_segment*::=**



(*storage_clause* , *size_clause*::=)

Semantics

rollback_segment

Specify the name of an existing rollback segment.

ONLINE

Specify `ONLINE` to bring the rollback segment online. When you create a rollback segment, it is initially offline and not available for transactions. This clause brings the rollback segment online, making it available for transactions by your instance. You can also bring a rollback segment online when you start your instance with the initialization parameter `ROLLBACK_SEGMENTS`.

> **See Also:**
>
> "Bringing a Rollback Segment Online: Example"

OFFLINE

Specify `OFFLINE` to take the rollback segment offline.

- If the rollback segment does not contain any information needed to roll back an active transaction, then Oracle Database takes it offline immediately.
- If the rollback segment does contain information for active transactions, then the database makes the rollback segment unavailable for future transactions and takes it offline after all the active transactions are committed or rolled back.

When the rollback segment is offline, it can be brought online by any instance.

To see whether a rollback segment is online or offline, query `STATUS` column of the data dictionary view `DBA_ROLLBACK_SEGS`. Online rollback segments have a value of `IN_USE`. Offline rollback segments have a value of `AVAILABLE`.

Restriction on Taking Rollback Segments Offline

You cannot take the SYSTEM rollback segment offline.

storage_clause

Use the *storage_clause* to change the storage characteristics of the rollback segment.

Restrictions on Rollback Segment Storage

You cannot change the value of INITIAL parameter. If the rollback segment is in a locally managed tablespace, then the only storage parameter you can change is OPTIMAL. If the rollback segment is in a dictionary-managed tablespace, then the only storage parameters you can change are NEXT, MINEXTENTS, MAXEXTENTS and OPTIMAL.

> **See Also:**
>
> *storage_clause* for syntax and additional information

SHRINK Clause

Specify SHRINK if you want Oracle Database to attempt to shrink the rollback segment to an optimal or specified size. The success and amount of shrinkage depend on the available free space in the rollback segment and how active transactions are holding space in the rollback segment.

If you do not specify TO *size_clause*, then the size defaults to the OPTIMAL value of the *storage_clause* of the CREATE ROLLBACK SEGMENT statement that created the rollback segment. If OPTIMAL was not specified, then the size defaults to the MINEXTENTS value of the *storage_clause* of the CREATE ROLLBACK SEGMENT statement.

Regardless of whether you specify TO *size_clause*:

- The value to which Oracle Database shrinks the rollback segment is valid for the execution of the statement. Thereafter, the size reverts to the OPTIMAL value of the CREATE ROLLBACK SEGMENT statement.
- The rollback segment cannot shrink to less than two extents.

To determine the actual size of a rollback segment after attempting to shrink it, query the BYTES, BLOCKS, and EXTENTS columns of the DBA_SEGMENTS view.

Restriction on Shrinking Rollback Segments

In an Oracle Real Application Clusters environment, you can shrink only rollback segments that are online to your instance.

> **See Also:**
>
> *size_clause* for information on that clause, and "Resizing a Rollback Segment: Example"

Examples

The following examples use the rbs_one rollback segment, which was created in "Creating a Rollback Segment: Example".

Bringing a Rollback Segment Online: Example

This statement brings the rollback segment `rbs_one` online:

```
ALTER ROLLBACK SEGMENT rbs_one ONLINE;
```

Resizing a Rollback Segment: Example

This statement shrinks the rollback segment `rbs_one`:

```
ALTER ROLLBACK SEGMENT rbs_one
   SHRINK TO 100M;
```

ALTER SEQUENCE

Purpose

Use the `ALTER SEQUENCE` statement to change the increment, minimum and maximum values, cached numbers, and behavior of an existing sequence. This statement affects only future sequence numbers.

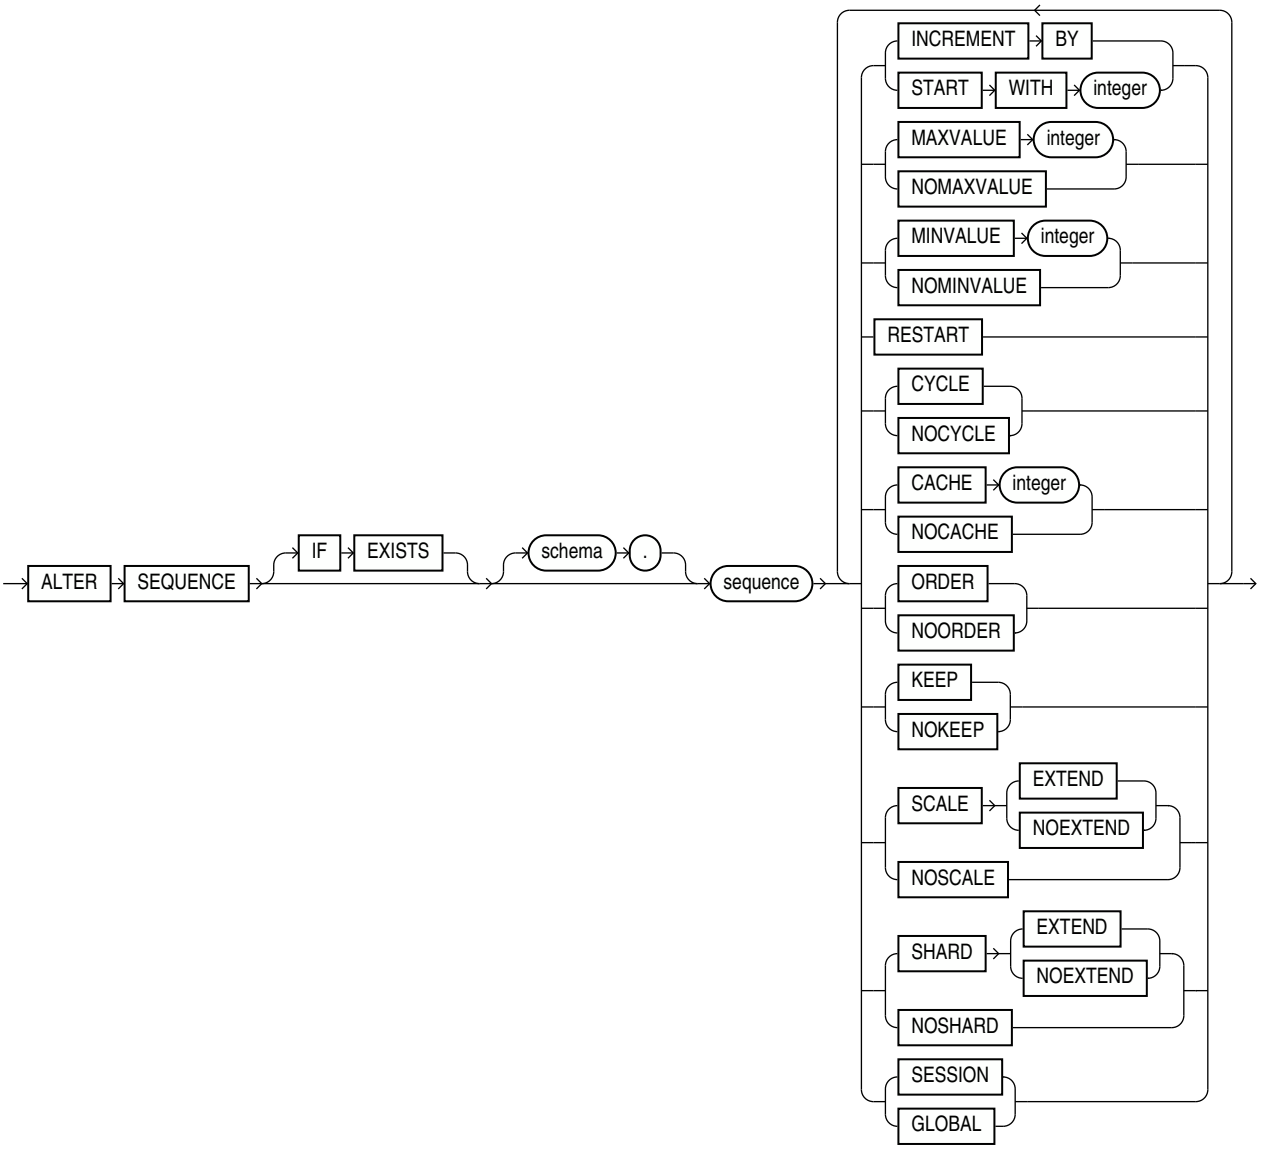
> **See Also:**
>
> CREATE SEQUENCE for additional information on sequences

Prerequisites

The sequence must be in your own schema, or you must have the `ALTER` object privilege on the sequence, or you must have the `ALTER ANY SEQUENCE` system privilege.

Syntax

***alter_sequence*::=**



Semantics

The keywords and parameters in this statement serve the same purposes they serve when you create a sequence.

- If you change the `INCREMENT BY` value before the first invocation of `NEXTVAL`, then some sequence numbers will be skipped. Therefore, if you want to retain the original `START WITH` value, you must drop the sequence and re-create it with the original `START WITH` value and the new `INCREMENT BY` value.
- Specify `RESTART` to reset `NEXTVAL` to `MINVALUE` for an ascending sequence. For a descending sequence `RESTART` resets `NEXTVAL` to `MAXVALUE`.

- To restart the sequence at a different number, specify `RESTART` with the `START WITH` clause to set the value at which the sequence restarts.
- If you alter the sequence by specifying the `KEEP` or `NOKEEP` clause between runtime and failover of a request, then the original value of `NEXTVAL` is not retained during replay for Application Continuity for that request.
- Oracle Database performs some validations. For example, a new `MAXVALUE` cannot be imposed that is less than the current sequence number.

> **See Also:**
>
> CREATE SEQUENCE for information on creating a sequence and DROP SEQUENCE for information on dropping and re-creating a sequence

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

SCALE

Use `SCALE` to enable sequence scalability. When `SCALE` is specified, a numeric offset is affixed to the beginning of the sequence which removes all duplicates in generated values.

EXTEND

If you specify `EXTEND` with `SCALE` the generated sequence values are all of length *(x+y)*, where *x* is the length of the scalable offset (default value is 6), and *y* is the maximum number of digits in the sequence *(maxvalue/minvalue)*.

When you use `SCALE` it is highly recommended that you not use `ORDER` simultaneously on the sequence.

NOEXTEND

`NOEXTEND` is the default setting for the `SCALE` clause. With the `NOEXTEND` setting, the generated sequence values are at most as wide as the maximum number of digits in the sequence `(maxvalue/minvalue)`. This setting is useful for integration with existing applications where sequences are used to populate fixed width columns.

SHARD

Use this clause to generate unique sequence numbers across shards.

The sequence object is created as a global, all-shards sharded object that returns unique sequence values across all shards. The sequence object is also created at the catalog database that returns unique sequence values relative to the shard databases.

The `EXTEND` and `NOEXTEND` keywords define the behavior of a sharded sequence.

EXTEND

When you specify `EXTEND` with the `SHARD` clause, the generated sequence values are all of length *(x + y)*, where *x* is the length of an(a) `SHARD` offset of size 3. The size 3 corresponds to

the width of the maximum number of shards i.e. 1000 affixed at the beginning of the sequence values. *y* is the maximum number of digits in the sequence *maxvalue/minvalue*.

NOEXTEND

The default setting for the SHARD clause is NOEXTEND.

When you specify NOEXTEND, the generated sequence values are at most as wide as the maximum number of digits in the sequence *maxvalue/minvalue*. This setting is useful for integration with existing applications where sequences are used to populate fixed width columns.

If you call NEXTVAL on a sequence with SHARD NOEXTEND specified, a user error is thrown, if the generated value requires more digits of representation than the *maxvalue/minvalue* of the sequence.

Sequence with SHARD and SCALE

If you specify the SCALE and the SHARD clauses together, the sequence generates scalable, globally unique values within a shard database for multiple instances and sessions.

If you specify EXTEND with the SCALE and SHARD clauses, the generated sequence values are all of length *(x+y+z)*, where *x* is the length of a SHARD offset with a default value of size 4, *y* is the length of the scalable offset with a default value of 6(5), and *z* is the maximum number of digits in the sequence *maxvalue/minvalue* .

If you specify EXTEND or NOEXTEND with the SHARD and SCALE clauses, it applies to both SHARD and SCALE. You do not need to specify EXTEND or NOEXTEND separately. If you specify the EXTEND or NOEXTEND option separately for both the SHARD and SCALE clauses, with the same or different value, a parsing error results, with a message of a duplicate or conflicting EXTEND clause.

When you use SHARD it is highly recommended that you not use ORDER simultaneously on the sequence.

You can use SHARD with CACHE and NOCACHE modes of operation.

> **Note:**
>
> - Starting with Oracle Database Release 23 a sharded sequence without scale will have the leading "1" of the offset removed.
> - Starting with Oracle Database Release 23 a sharded sequence with scale will have the leading "1" of the offset removed.
>
> Prior to Release 23, a a sharded sequence with scale had one leading "1" for the combined offset. This leading "1" is removed from Release 23 onwards.

Examples

Modifying a Sequence: Examples

This statement sets a new maximum value for the customers_seq sequence, which was created in "Creating a Sequence: Example":

```
ALTER SEQUENCE customers_seq
   MAXVALUE 1500;
```

This statement turns on `CYCLE` and `CACHE` for the `customers_seq` sequence:

```
ALTER SEQUENCE customers_seq
   CYCLE
   CACHE 5;
```

ALTER SESSION

Purpose

Use the `ALTER SESSION` statement to set or modify any of the conditions or parameters that affect your connection to the database. The statement stays in effect until you disconnect from the database.

Prerequisites

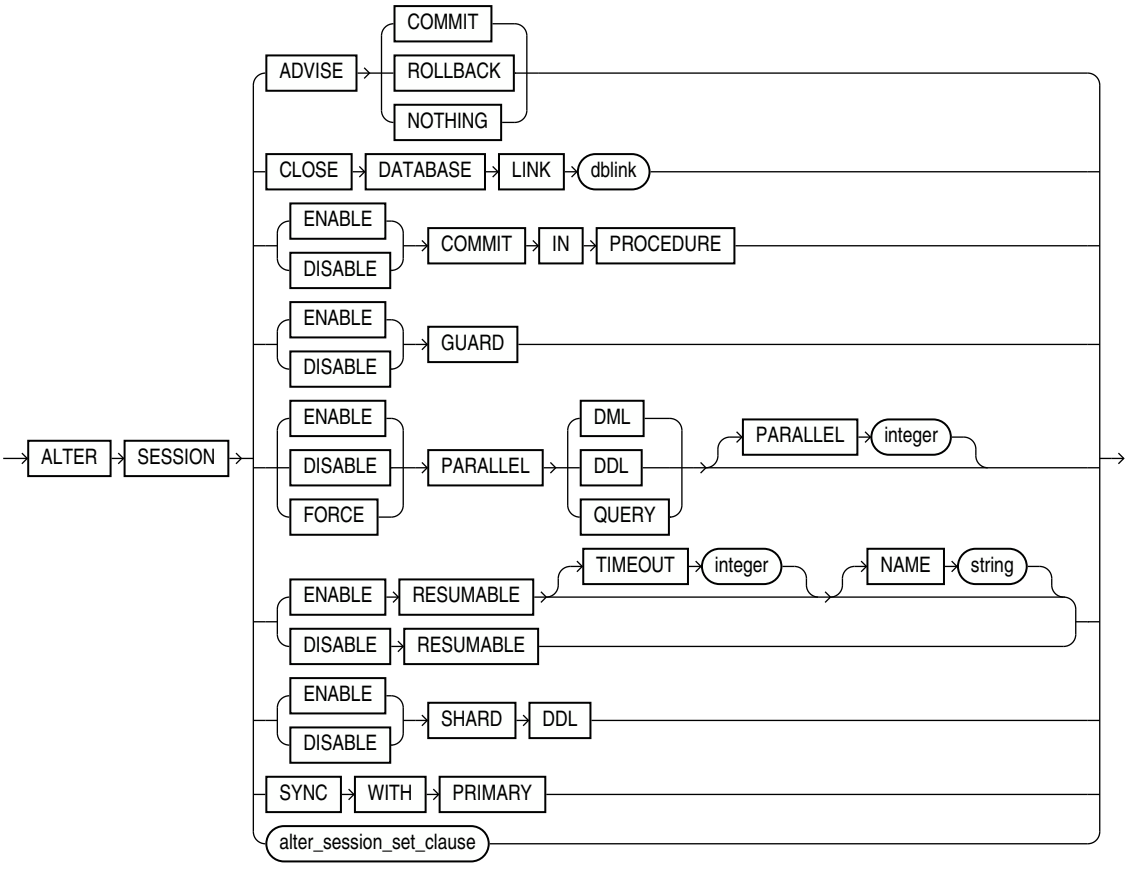
To enable and disable the SQL trace facility, you must have `ALTER SESSION` system privilege.

To enable or disable resumable space allocation, you must have the `RESUMABLE` system privilege.

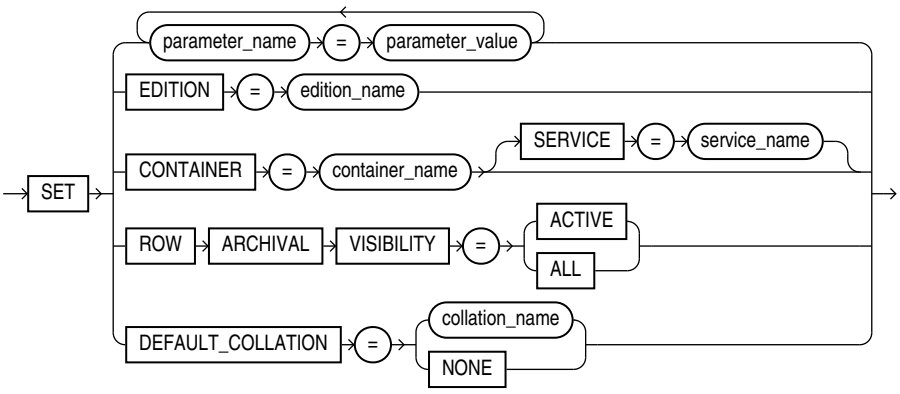
You do not need any privileges to perform the other operations of this statement unless otherwise indicated.

Syntax

***alter_session*::=**



***alter_session_set_clause*::=**



Semantics

ADVISE Clause

The `ADVISE` clause sends advice to a remote database to force a distributed transaction. The advice appears in the `ADVICE` column of the `DBA_2PC_PENDING` view on the remote database (the values are '`C`' for `COMMIT`, '`R`' for `ROLLBACK`, and ' ' for `NOTHING`). If the transaction becomes in doubt, then the administrator of that database can use this advice to decide whether to commit or roll back the transaction.

You can send different advice to different remote databases by issuing multiple `ALTER SESSION` statements with the `ADVISE` clause in a single transaction. Each such statement sends advice to the databases referenced in the following statements in the transaction until another such statement is issued.

> **See Also:**
>
> "Forcing a Distributed Transaction: Example"

CLOSE DATABASE LINK Clause

Specify `CLOSE DATABASE LINK` to close the database link *`dblink`*. When you issue a statement that uses a database link, Oracle Database creates a session for you on the remote database using that link. The connection remains open until you end your local session or until the number of database links for your session exceeds the value of the initialization parameter `OPEN_LINKS`. If you want to reduce the network overhead associated with keeping the link open, then use this clause to close the link explicitly if you do not plan to use it again in your session.

> **See Also:**
>
> Closing a Database Link: Example

ENABLE | DISABLE COMMIT IN PROCEDURE

Procedures and stored functions written in PL/SQL can issue `COMMIT` and `ROLLBACK` statements. If your application would be disrupted by a `COMMIT` or `ROLLBACK` statement not issued directly by the application itself, then specify `DISABLE COMMIT IN PROCEDURE` clause to prevent procedures and stored functions called during your session from issuing these statements.

You can subsequently allow procedures and stored functions to issue `COMMIT` and `ROLLBACK` statements in your session by issuing the `ENABLE COMMIT IN PROCEDURE`.

Some applications automatically prohibit `COMMIT` and `ROLLBACK` statements in procedures and stored functions. Refer to your application documentation for more information.

ENABLE | DISABLE GUARD

The *`security_clause`* of `ALTER DATABASE` lets you prevent anyone other than the `SYS` user from making any changes to data or database objects on the primary or standby database. This clause lets you override that setting for the current session.

> **See Also:**
>
> *security_clause* for more information on the `GUARD` setting

PARALLEL DML | DDL | QUERY

The `PARALLEL` parameter determines whether all subsequent DML, DDL, or query statements in the session will be considered for parallel execution. This clause enables you to override the degree of parallelism of tables during the current session without changing the tables themselves. Uncommitted transactions must either be committed or rolled back prior to executing this clause for DML.

> **See Also:**
>
> "Enabling Parallel DML: Example"

ENABLE Clause

Specify `ENABLE` to execute subsequent statements in the session in parallel. This is the default for DDL and query statements.

- `DML`: DML statements are executed in parallel mode if a parallel hint or a parallel clause is specified.
- `DDL`: DDL statements are executed in parallel mode if a parallel clause is specified.
- `QUERY`: Queries are executed in parallel mode if a parallel hint or a parallel clause is specified.

Restriction on the ENABLE clause

You cannot specify the optional `PARALLEL` *`integer`* with `ENABLE`.

DISABLE Clause

Specify `DISABLE` to execute subsequent statements in the session serially. This is the default for DML statements.

- `DML`: DML statements are executed serially.
- `DDL`: DDL statements are executed serially.
- `QUERY`: Queries are executed serially.

Restriction on the DISABLE clause

You cannot specify the optional `PARALLEL` *`integer`* with `DISABLE`.

FORCE Clause

`FORCE` forces parallel execution of subsequent statements in the session. If no parallel clause or hint is specified, then a default degree of parallelism is used. This clause overrides any *`parallel_clause`* specified in subsequent statements in the session but is overridden by a parallel hint.

- `DML`: Provided no parallel DML restrictions are violated, subsequent DML statements in the session are executed with the default degree of parallelism, unless a degree is specified in this clause.
- `DDL`: Subsequent DDL statements in the session are executed with the default degree of parallelism, unless a degree is specified in this clause. Resulting database objects will have associated with them the prevailing degree of parallelism.

  Specifying `FORCE DDL` automatically causes all tables created in this session to be created with a default level of parallelism. The effect is the same as if you had specified the *`parallel_clause`* (with the default degree) in the `CREATE TABLE` statement.
- `QUERY`: Subsequent queries are executed with the default degree of parallelism, unless a degree is specified in this clause.

PARALLEL *integer*

Specify an integer to explicitly specify a degree of parallelism:

- For `FORCE DDL`, the degree overrides any parallel clause in subsequent DDL statements.
- For `FORCE DML` and `QUERY`, the degree overrides the degree currently stored for the table in the data dictionary.
- A degree specified in a statement through a hint will override the degree being forced.

The following types of DML operations are not parallelized regardless of this clause:

- Operations on cluster tables
- Operations with embedded functions that either write or read database or package states
- Operations on tables with triggers that could fire
- Operations on tables or schema objects containing object types, or `LONG` or LOB data types

RESUMABLE Clauses

These clauses let you enable and disable resumable space allocation. This feature allows an operation to be suspended in the event of an out-of-space error condition and to resume automatically from the point of interruption when the error condition is fixed.

> **Note:**
>
> Resumable space allocation is fully supported for operations on locally managed tablespaces. Some restrictions apply if you are using dictionary-managed tablespaces. For information on these restrictions, refer to *Oracle Database Administrator's Guide*.

ENABLE RESUMABLE

This clause enables resumable space allocation for the session.

TIMEOUT

`TIMEOUT` lets you specify (in seconds) the time during which an operation can remain suspended while waiting for the error condition to be fixed. If the error condition is not fixed within the `TIMEOUT` period, then Oracle Database aborts the suspended operation.

NAME

`NAME` lets you specify a user-defined text string to help users identify the statements issued during the session while the session is in resumable mode. Oracle Database inserts the text string into the `USER_RESUMABLE` and `DBA_RESUMABLE` data dictionary views. If you do not specify `NAME`, then Oracle Database inserts the default string '`User` *`username`*`(`*`userid`*`), Session` *`sessionid`*`, Instance` *`instanceid`*'.

> **See Also:**
>
> *Oracle Database Reference* for information on the data dictionary views

DISABLE RESUMABLE

This clause disables resumable space allocation for the session.

SHARD DDL Clauses

These clauses are valid only if you are connected to a sharded database. They let you control whether DDLs issued in the session are issued against the shard catalog database and all shards, or against only the shard catalog database.

- If you specify `ENABLE SHARD DDL`, then DDLs issued in the session are issued against the shard catalog database and all shards. This mode is the default for the SDB user—a user that exists in the shard catalog database and in all shards.
- If you specify `DISABLE SHARD DDL`, then DDLs issued in the session are issued against only the shard catalog database. This mode is the default for a local user—a user that exists only in the shard catalog database.

> **See Also:**
>
> *Using Oracle Sharding*

SYNC WITH PRIMARY

Use this clause to synchronize redo apply on a physical standby database with the primary database. An `ALTER SESSION` statement with this clause blocks until redo apply has applied all redo data received by the standby at the time the statement is issued. This clause returns an error, and synchronization does not occur, if the redo transport state for the standby database is not `SYNCHRONIZED` or if redo apply is not active.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information on this session parameter

alter_session_set_clause

Use the *alter_session_set_clause* to set initialization parameter values or to set an edition for the current session.

Initialization Parameters

You can set two types of parameters using this clause:

- Initialization parameters that are dynamic in the scope of the `ALTER SESSION` statement (listed in "Initialization Parameters and ALTER SESSION")
- Session parameters (listed in "Session Parameters and ALTER SESSION ")

You can set values for multiple parameters in the same *alter_session_set_clause*.

EDITION

Specify `EDITION` = *edition* to set the specified edition as the edition in the database session. You must have the `USE` object privilege on *edition*, *edition* must already have been created, and it must be `USABLE`.

When this statement is successful, the database discards PL/SQL package state corresponding to editionable packages but retains package state corresponding to packages that are not editionable.

You can also set the edition for the current session at startup with the `EDITION` parameter of the SQL*Plus `CONNECT` command. However, you cannot specify an `ALTER SESSION SET EDITION` statement in a recursive SQL or PL/SQL block.

You can determine the edition in use by the current session with the following query:

```
SELECT SYS_CONTEXT('USERENV', 'CURRENT_EDITION_NAME') FROM DUAL;
```

> **See Also:**
>
> CREATE EDITION for more information on editions and *Oracle Database PL/SQL Language Reference* for information on how editions are designated as `USABLE`

CONTAINER

Use this clause in a multitenant container database (CDB) to switch to the container specified by *container_name*.

To use this clause, you must be a common user with the SET CONTAINER privilege, either granted commonly or granted locally in *container_name*.

For *container_name*, specify one of the following:

- CDB$ROOT to switch to the root
- PDB$SEED to switch to the seed
- A pluggable database (PDB) name to switch to that PDB. You can view the names of the PDBs in a CDB by querying the DBA_PDBS view.

You can determine the container to which the current session is connected by using the SQL*Plus SHOW CON_NAME command or with the following SQL query:

```
SELECT SYS_CONTEXT('USERENV', 'CON_NAME') FROM DUAL;
```

SERVICE

By default, when you switch to a container, the session uses the default service for the container. Specify the SERVICE clause to use a different service for the container. For *service_name*, specify the name of the service you want to use.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information on switching to a container

ROW ARCHIVAL VISIBILITY

Use this clause to configure row archival visibility for the session. This clause lets you implement In-Database Archiving, which allows you to designate table rows as active or archived. You can then perform queries on only the active rows within the table.

- If you specify ACTIVE, then the database will consider only active rows when performing queries on tables that are enabled for row archival. This is the default.
- If you specify ALL, then the database will consider all rows when performing queries on tables that are enabled for row archival.

This clause has no effect on queries on tables that are not enabled for row archival.

> **See Also:**
>
> - The `CREATE TABLE` ROW ARCHIVAL clause to learn how to enable a new table for row archival
> - The `ALTER TABLE` [NO] ROW ARCHIVAL clause to learn how to enable or disable an existing table for row archival
> - *Oracle Database VLDB and Partitioning Guide* for more information on In-Database Archiving

DEFAULT_COLLATION

Use this clause to set the default collation for the session.

- Use *`collation_name`* to specify the default collation for the session. You can specify the name of any valid named collation or pseudo-collation. This collation becomes the *effective schema default collation*. This collation is assigned to tables, views, and materialized views that are subsequently created in any schema for the duration of the session. The default collation for the session does not get propagated to any remote sessions connected to the current session using DB links.
- If you specify `NONE`, then there is no default collation for the session. In this case, the default collation for a particular schema becomes the *effective schema default collation* for that schema. That default collation is assigned to tables, views, and materialized views that are subsequently created in the schema for the duration of the session.

In either of the preceding cases, you can override the effective schema default collation and assign a default collation to a particular table, materialized view, or view by specifying the `DEFAULT COLLATION` clause of the `CREATE` or `ALTER` statement for the table, materialized view, or view.

The effective schema default collation also affects the DDL statements `CREATE FUNCTION`, `CREATE PACKAGE`, `CREATE PROCEDURE`, `CREATE TRIGGER`, and `CREATE TYPE`. Refer to *Oracle Database PL/SQL Language Reference* for more details on these statements.

You can query the default collation for a session with the following statement:

```
SELECT SYS_CONTEXT('USERENV', 'SESSION_DEFAULT_COLLATION') FROM DUAL;
```

You can specify the `SET DEFAULT_COLLATION` clause only if the `COMPATIBLE` initialization parameter is set to `12.2` or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

> **See Also:**
>
> The DEFAULT COLLATION Clause clause of `CREATE USER` for more information on the default collation of a schema

> **Note:**
>
> The effective schema default collation for a session should not be confused with the session parameter NLS_SORT. The effective schema default collation is used by DDL statements to decide the default data-bound collation of tables, views, and materialized views when they are created. The session parameter NLS_SORT points to a named collation that is used when Oracle executes a query, a DML statement, or PL/SQL code containing a SQL operation whose determined collation is a pseudo-collation, such as USING_NLS_COMP or USING_NLS_SORT. Refer to *Oracle Database Globalization Support Guide* for more information.

Initialization Parameters and ALTER SESSION

Some initialization parameter are dynamic in the scope of ALTER SESSION. When you set these parameters using ALTER SESSION, the value you set persists only for the duration of the current session.To determine whether a parameter can be altered using an ALTER SESSION statement, query the ISSES_MODIFIABLE column of the V$PARAMETER dynamic performance view.

> **Note:**
>
> Before changing the values of initialization parameters, refer to their full description in *Oracle Database Reference*.

A number of parameters that can be set using ALTER SESSION are not initialization parameters. You can set them only with ALTER SESSION, not in an initialization parameter file. Those session parameters are described in "Session Parameters and ALTER SESSION ".

Session Parameters and ALTER SESSION

The following parameters are session parameters only, not initialization parameters:

CONSTRAINT[S]

Syntax:

```
CONSTRAINT[S] = { IMMEDIATE | DEFERRED | DEFAULT }
```

The CONSTRAINT[S] parameter determines when conditions specified by a deferrable constraint are enforced.

- IMMEDIATE indicates that the conditions specified by the deferrable constraint are checked immediately after each DML statement. This setting is equivalent to issuing the SET CONSTRAINTS ALL IMMEDIATE statement at the beginning of each transaction in your session.
- DEFERRED indicates that the conditions specified by the deferrable constraint are checked when the transaction is committed. This setting is equivalent to issuing the SET CONSTRAINTS ALL DEFERRED statement at the beginning of each transaction in your session.
- DEFAULT restores all constraints at the beginning of each transaction to their initial state of DEFERRED or IMMEDIATE.

CURRENT_SCHEMA

Syntax:

```
CURRENT_SCHEMA = schema
```

The CURRENT_SCHEMA parameter changes the current schema of the session to the specified schema. Subsequent unqualified references to schema objects during the session will resolve to objects in the specified schema. The setting persists for the duration of the session or until you issue another ALTER SESSION SET CURRENT_SCHEMA statement.

This setting offers a convenient way to perform operations on objects in a schema other than that of the current user without having to qualify the objects with the schema name. This setting changes the current schema, but it does not change the session user or the current user, nor does it give the session user any additional system or object privileges for the session.

ERROR_ON_OVERLAP_TIME

Syntax:

```
ERROR_ON_OVERLAP_TIME = {TRUE | FALSE}
```

The ERROR_ON_OVERLAP_TIME parameter determines how Oracle Database should handle an ambiguous boundary datetime value—a case in which it is not clear whether the datetime is in standard or daylight saving time.

- Specify TRUE to return an error for the ambiguous overlap timestamp.
- Specify FALSE to default the ambiguous overlap timestamp to the standard time. This is the default.

Refer to "Support for Daylight Saving Times " for more information on boundary datetime values.

FLAGGER

Syntax:

```
FLAGGER = { ENTRY | OFF }
```

The FLAGGER parameter specifies FIPS flagging (as specified in Federal Information Processing Standard 127-2), which causes an error message to be generated when a SQL statement issued is an extension of the Entry Level of SQL-92 (officially, ANSI X3.135-1992, a standard that is now superseded by SQL:2016). FLAGGER is a session parameter only, not an initialization parameter.

After flagging is set in a session, a subsequent ALTER SESSION SET FLAGGER statement will work, but generates the message, ORA-00097. This allows FIPS flagging to be altered without disconnecting the session. OFF turns off flagging.

> **See Also:**
>
> Oracle and Standard SQL, for more information about Oracle compliance with current ANSI SQL standards
>
> Starting with Oracle Database 23ai, several parameters associated with `FIPS_140` are deprecated.
>
> `FIPS_140` in `FIPS.ORA` can be used to enable `FIPS` for all features starting with Oracle Database 23ai. The following FIPS parameters are deprecated:
>
> - SQLNET.ORA: `FIPS_140` to enable FIPS for native network encryption
> - FIPS.ORA: `SSLFIPS_140` to enable FIPS for TLS
> - Initialization parameter: `DBFIPS_140` to enable FIPS for TDE and `DBMS_CRYPTO`

INSTANCE

Syntax:

```
INSTANCE = integer
```

Setting the `INSTANCE` parameter lets you access another instance as if you were connected to your own instance. `INSTANCE` is a session parameter only, not an initialization parameter. In an Oracle Real Application Clusters (Oracle RAC) environment, each Oracle RAC instance retains static or dynamic ownership of disk space for optimal DML performance based on the setting of this parameter.

ISOLATION_LEVEL

Syntax:

```
ISOLATION_LEVEL = {SERIALIZABLE | READ COMMITTED}
```

The `ISOLATION_LEVEL` parameter specifies how transactions containing database modifications are handled. `ISOLATION_LEVEL` is a session parameter only, not an initialization parameter.

- `SERIALIZABLE` indicates that transactions in the session use the serializable transaction isolation mode as specified in the SQL standard. If a serializable transaction attempts to execute a DML statement that updates rows currently being updated by another uncommitted transaction at the start of the serializable transaction, then the DML statement fails. A serializable transaction can see its own updates.
- `READ COMMITTED` indicates that transactions in the session will use the default Oracle Database transaction behavior. If the transaction contains DML that requires row locks held by another transaction, then the DML statement will wait until the row locks are released.

> **Note:**
>
> Serializable transactions do not work with deferred segment creation or interval partitioning. Trying to insert data into an empty table with no segment created, or into a partition of an interval partitioned table that does not yet have a segment, causes an error.

STANDBY_MAX_DATA_DELAY

Syntax:

```
STANDBY_MAX_DATA_DELAY =  { integer | NONE }
```

In an Active Data Guard environment, this session parameter can be used to specify a session-specific apply lag tolerance, measured in seconds, for queries issued by non-administrative users to a physical standby database that is in real-time query mode. This capability allows queries to be safely offloaded from the primary database to a physical standby database, because it is possible to detect if the standby database has become unacceptably stale.

If `STANDBY_MAX_DATA_DELAY` is set to the default value of `NONE`, queries issued to a physical standby database will be executed regardless of the apply lag on that database.

If `STANDBY_MAX_DATA_DELAY` is set to a nonzero value, a query issued to a physical standby database will be executed only if the apply lag is less than or equal to `STANDBY_MAX_DATA_DELAY`. Otherwise, an `ORA-3172` error is returned to alert the client that the apply lag is too large.

If `STANDBY_MAX_DATA_DELAY` is set to `0`, a query issued to a physical standby database is guaranteed to return the exact same result as if the query were issued on the primary database, unless the standby database is lagging behind the primary database, in which case an `ORA-3172` error is returned.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information on Active Data Guard and using this session parameter

TIME_ZONE

Syntax:

```
TIME_ZONE =  '[+ | -] hh:mi'
             | LOCAL
             | DBTIMEZONE
             | 'time_zone_region'
```

The `TIME_ZONE` parameter specifies the default local time zone offset or region name for the current SQL session. `TIME_ZONE` is a session parameter only, not an initialization parameter. To determine the time zone of the current session, query the built-in function `SESSIONTIMEZONE` (see SESSIONTIMEZONE).

- Specify a format mask (`'[+|-]hh:mi'`) indicating the hours and minutes before or after UTC (Coordinated Universal Time—formerly Greenwich Mean Time). The valid range for *hh:mi* is -12:00 to +14:00.
- Specify `LOCAL` to set the default local time zone offset of the current SQL session to the original default local time zone offset that was established when the current SQL session was started.
- Specify `DBTIMEZONE` to set the current session time zone to match the value set for the database time zone. If you specify this setting, then the `DBTIMEZONE` function will return the database time zone as a UTC offset or a time zone region, depending on how the database time zone has been set.
- Specify a valid *time_zone_region*. To see a listing of valid time zone region names, query the `TZNAME` column of the `V$TIMEZONE_NAMES` dynamic performance view. If you specify this setting, then the `SESSIONTIMEZONE` function will return the region name.

> **Note:**
>
> Time zone region names are needed by the daylight saving feature. These names are stored in two types of time zone files: one large and one small. One of these files is the default file, depending on your environment and the release of Oracle Database you are using. For more information regarding time zone files and names, see *Oracle Database Globalization Support Guide*.

> **See Also:**
>
> *Oracle Database Globalization Support Guide* for a complete listing of the time zone region names in both files

> **Note:**
>
> You can also set the default client session time zone using the `ORA_SDTZ` environment variable. Refer to *Oracle Database Globalization Support Guide* for more information on this variable.

USE_PRIVATE_OUTLINES

Syntax:

```
USE_PRIVATE_OUTLINES = { TRUE | FALSE | category_name }
```

The `USE_PRIVATE_OUTLINES` parameter lets you control the use of private outlines. When this parameter is enabled and an outlined SQL statement is issued, the optimizer retrieves the outline from the session private area rather than the public area used when `USE_STORED_OUTLINES` is enabled. If no outline exists in the session private area, then the optimizer will not use an outline to compile the statement. `USE_PRIVATE_OUTLINES` is not an initialization parameter.

- TRUE causes the optimizer to use private outlines stored in the DEFAULT category when compiling requests.
- FALSE specifies that the optimizer should not use stored private outlines. This is the default. If USE_STORED_OUTLINES is enabled, then the optimizer will use stored public outlines.
- *category_name* causes the optimizer to use outlines stored in the *category_name* category when compiling requests.

Restriction on USE_PRIVATE_OUTLINES

You cannot enable this parameter if USE_STORED_OUTLINES is enabled.

USE_STORED_OUTLINES

> **Note:**
>
> Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. Refer to *Oracle Database SQL Tuning Guide* for more information about SQL plan management.

Syntax:

```
USE_STORED_OUTLINES = { TRUE | FALSE | category_name }
```

The USE_STORED_OUTLINES parameter determines whether the optimizer will use stored public outlines to generate execution plans. USE_STORED_OUTLINES is not an initialization parameter.

- TRUE causes the optimizer to use outlines stored in the DEFAULT category when compiling requests.
- FALSE specifies that the optimizer should not use stored outlines. This is the default.
- *category_name* causes the optimizer to use outlines stored in the *category_name* category when compiling requests.

Restriction on USED_STORED_OUTLINES

You cannot enable this parameter if USE_PRIVATE_OUTLINES is enabled.

Examples

Enabling Parallel DML: Example

Issue the following statement to enable parallel DML mode for the current session:

```
ALTER SESSION ENABLE PARALLEL DML;
```

Forcing a Distributed Transaction: Example

The following transaction inserts an employee record into the employees table on the database identified by the database link remote and deletes an employee record from the employees table on the database identified by local:

```
ALTER SESSION
   ADVISE COMMIT;
```

```
INSERT INTO employees@remote
   VALUES (8002, 'Juan', 'Fernandez', 'juanf@example.com', NULL,
   TO_DATE('04-OCT-1992', 'DD-MON-YYYY'), 'SA_CLERK', 3000,
   NULL, 121, 20);

ALTER SESSION
   ADVISE ROLLBACK;

DELETE FROM employees@local
   WHERE employee_id = 8002;

COMMIT;
```

This transaction has two `ALTER SESSION` statements with the `ADVISE` clause. If the transaction becomes in doubt, then `remote` is sent the advice '`COMMIT`' by virtue of the first `ALTER SESSION` statement and `local` is sent the advice '`ROLLBACK`' by virtue of the second statement.

Closing a Database Link: Example

This statement updates the `jobs` table on the `local` database using a database link, commits the transaction, and explicitly closes the database link:

```
UPDATE jobs@local SET min_salary = 3000
   WHERE job_id = 'SH_CLERK';

COMMIT;

ALTER SESSION
   CLOSE DATABASE LINK local;
```

Changing the Date Format Dynamically: Example

The following statement dynamically changes the default date format for your session to `'YYYY MM DD-HH24:MI:SS'`:

```
ALTER SESSION
   SET NLS_DATE_FORMAT = 'YYYY MM DD HH24:MI:SS';
```

Oracle Database uses the new default date format:

```
SELECT TO_CHAR(SYSDATE) Today
   FROM DUAL;

TODAY
-------------------
2001 04 12 12:30:38
```

Changing the Date Language Dynamically: Example

The following statement changes the language for date format elements to French:

```
ALTER SESSION
   SET NLS_DATE_LANGUAGE = French;

SELECT TO_CHAR(SYSDATE, 'Day DD Month YYYY') Today
   FROM DUAL;

TODAY
---------------------------
Jeudi    12 Avril     2001
```

Changing the ISO Currency: Example

The following statement dynamically changes the ISO currency symbol to the ISO currency symbol for the territory America:

```
ALTER SESSION
   SET NLS_ISO_CURRENCY = America;

SELECT TO_CHAR( SUM(salary), 'C999G999D99') Total
   FROM employees;

TOTAL
------------------
     USD694,900.00
```

Changing the Decimal Character and Group Separator: Example

The following statement dynamically changes the decimal character to comma (,) and the group separator to period (.):

```
ALTER SESSION SET NLS_NUMERIC_CHARACTERS = ',.' ;
```

Oracle Database returns these new characters when you use their number format elements:

```
ALTER SESSION SET NLS_CURRENCY = 'FF';

SELECT TO_CHAR( SUM(salary), 'L999G999D99') Total FROM employees;

TOTAL
---------------------
         FF694.900,00
```

Changing the NLS Currency: Example

The following statement dynamically changes the local currency symbol to 'DM':

```
ALTER SESSION
   SET NLS_CURRENCY = 'DM';

SELECT TO_CHAR( SUM(salary), 'L999G999D99') Total
   FROM employees;

TOTAL
---------------------
         DM694.900,00
```

Changing the NLS Language: Example

The following statement dynamically changes to French the language in which error messages are displayed:

```
ALTER SESSION
   SET NLS_LANGUAGE = FRENCH;

Session modifiee.

SELECT * FROM DMP;

ORA-00942: Table ou vue inexistante
```

Changing the Linguistic Sort Sequence: Example

The following statement dynamically changes the linguistic sort sequence to Spanish:

```
ALTER SESSION
   SET NLS_SORT = XSpanish;
```

Oracle Database sorts character values based on their position in the Spanish linguistic sort sequence.

Enabling Query Rewrite: Example

This statement enables query rewrite in the current session for all materialized views that have not been explicitly disabled:

```
ALTER SESSION
  SET QUERY_REWRITE_ENABLED = TRUE;
```

12

SQL Statements: ALTER SYNONYM to COMMENT

This chapter contains the following SQL statements:

- ALTER SYNONYM
- ALTER SYSTEM
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TABLESPACE SET
- ALTER TRIGGER
- ALTER TYPE
- ALTER USER
- ALTER VIEW
- ANALYZE
- ASSOCIATE STATISTICS
- AUDIT (Traditional Auditing)
- AUDIT (Unified Auditing)
- CALL
- COMMENT

ALTER SYNONYM

Purpose

Use the `ALTER SYNONYM` statement to modify an existing synonym.

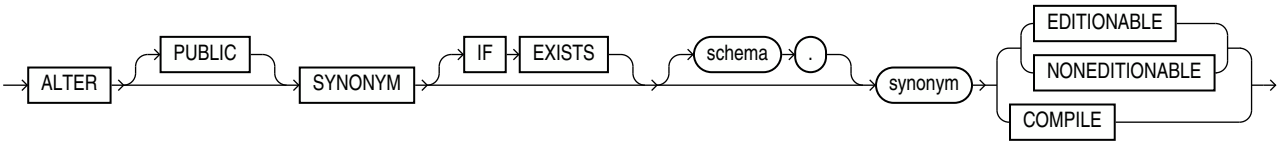
Prerequisites

To modify a private synonym in another user's schema, you must have the `CREATE ANY SYNONYM` and `DROP ANY SYNONYM` system privileges.

To modify a `PUBLIC` synonym, you must have the `CREATE PUBLIC SYNONYM` and `DROP PUBLIC SYNONYM` system privileges.

Syntax

***alter_synonym*::=**



Semantics

PUBLIC

Specify `PUBLIC` if *`synonym`* is a public synonym. You cannot use this clause to change a public synonym to a private synonym, or vice versa.

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

schema

Specify the schema containing the synonym. If you omit *`schema`*, then Oracle Database assumes the synonym is in your own schema.

synonym

Specify the name of the synonym to be altered.

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the synonym becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `SYNONYM` in *`schema`*. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

Restriction on EDITIONABLE | NONEDITIONABLE

You cannot specify these clauses for a public synonym because editioning is always enabled for the object type `SYNONYM` in the `PUBLIC` schema.

COMPILE

Use this clause to compile *`synonym`*. A synonym places a dependency on its target object and becomes invalid if the target object is changed or dropped. When you compile an invalid synonym, it becomes valid again.

> **Note:**
>
> You can determine if a synonym is valid or invalid by querying the `STATUS` column of the `ALL_`, `DBA_`, and `USER_OBJECTS` data dictionary views.

Examples

The following examples modify synonyms that were created in the `CREATE SYNONYM` "Examples".

The following statement compiles synonym `offices`:

```
ALTER SYNONYM offices COMPILE;
```

The following statement compiles public synonym `emp_table`:

```
ALTER PUBLIC SYNONYM emp_table COMPILE;
```

The following statement causes synonym `offices` to remain a noneditioned object if editioning is later enabled for schema object type `SYNONYM` in the schema that contains the synonym `offices`:

```
ALTER SYNONYM offices NONEDITIONABLE;
```

ALTER SYSTEM

Purpose

Use the `ALTER SYSTEM` statement to dynamically alter your Oracle Database instance. The settings stay in effect as long as the database is mounted.

When you use the `ALTER SYSTEM` statement in a multitenant container database (CDB), you can specify some clauses to alter the CDB as a whole and other clauses to alter a specific pluggable database (PDB).

> **See Also:**
>
> *Oracle Database Administrator's Guide* for complete information on using the `ALTER SYSTEM` statement in a CDB

Prerequisites

To specify the `RELOCATE CLIENT` clause, you must be authenticated `AS SYSASM`.

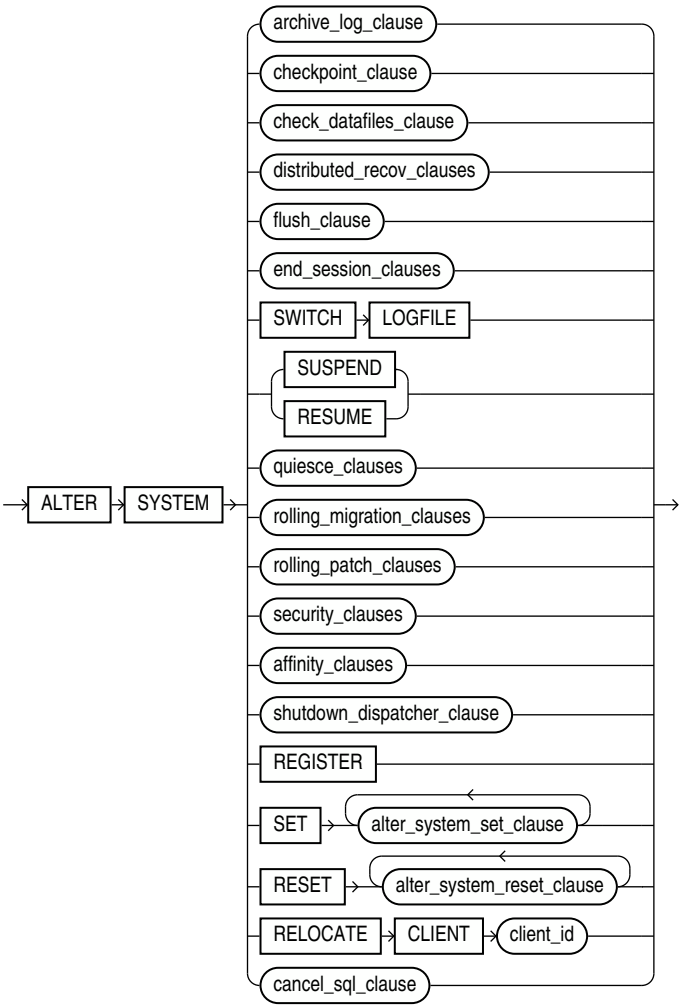
To specify all other clauses, you must have the `ALTER SYSTEM` system privilege.

If you are connected to a CDB:

- To alter the CDB as a whole, the current container must be the root and you must have the commonly granted `ALTER SYSTEM` privilege.
- To alter a PDB, the current container must be the PDB and you must have the `ALTER SYSTEM` privilege, either granted commonly or granted locally in the PDB.

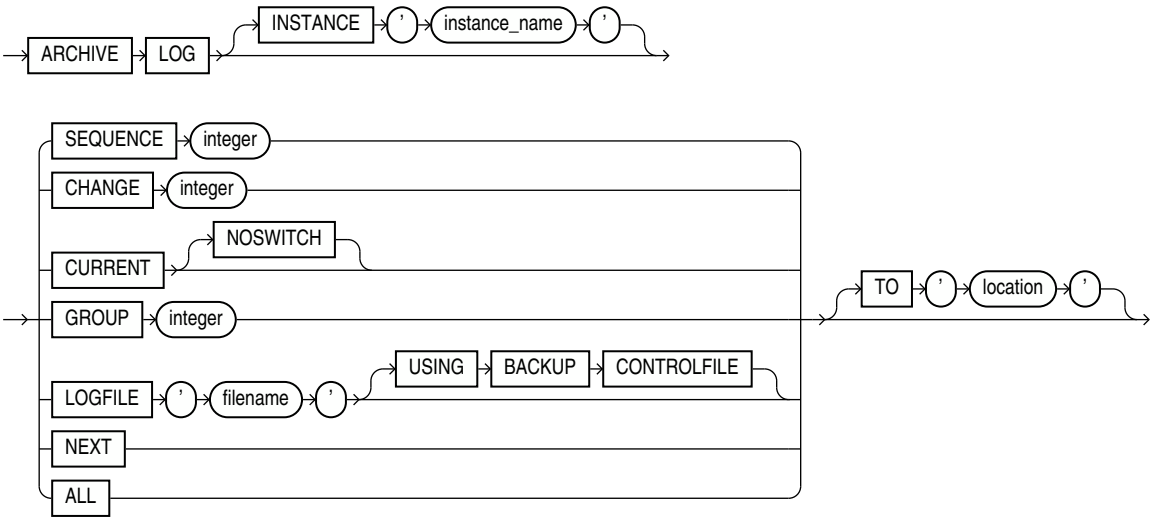
Syntax

***alter_system*::=**

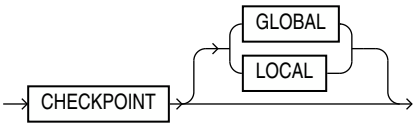


(*archive_log_clause*::=, *checkpoint_clause*::=, *check_datafiles_clause*::=, *distributed_recov_clauses*::=, *end_session_clauses*::=, *quiesce_clauses*::=, *rolling_migration_clauses*::=, *rolling_patch_clauses*::=, *security_clauses*::=, *shutdown_dispatcher_clause*::=, *alter_system_set_clause*::=, *alter_system_reset_clause*::=, cancel_sql_clause)

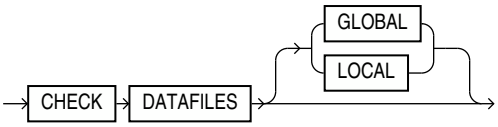
***archive_log_clause*::=**



***checkpoint_clause*::=**

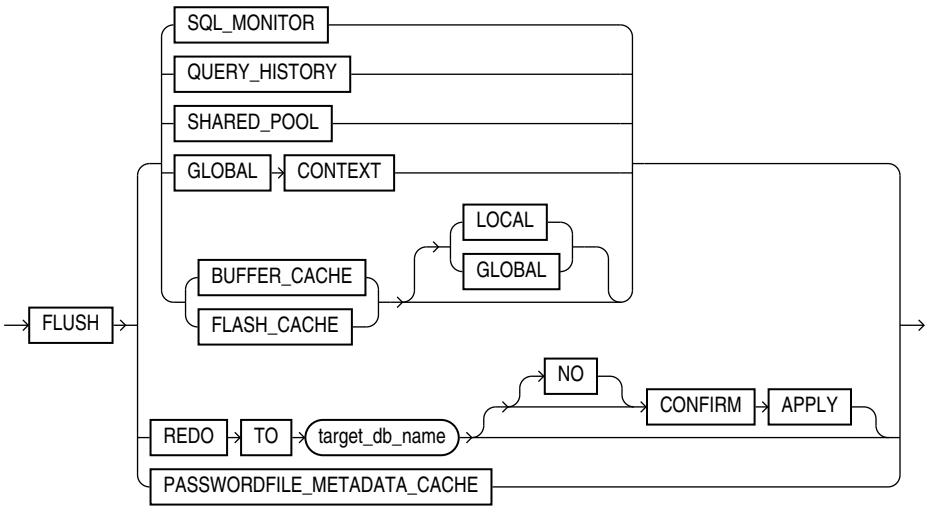


***check_datafiles_clause*::=**

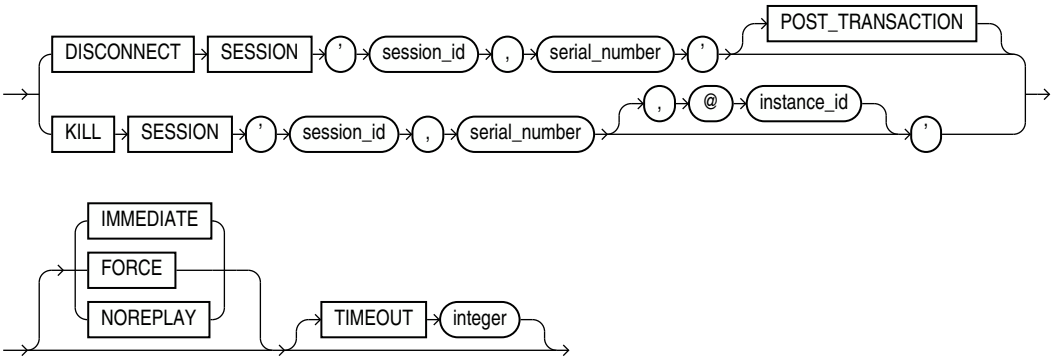


***distributed_recov_clauses*::=**

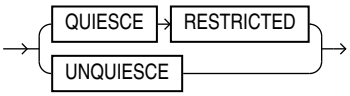
flush_clause



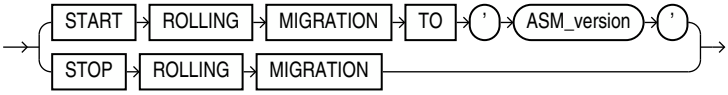
***end_session_clauses*::=**



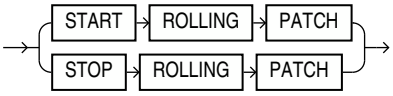
***quiesce_clauses*::=**



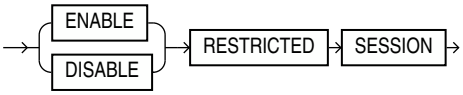
***rolling_migration_clauses*::=**



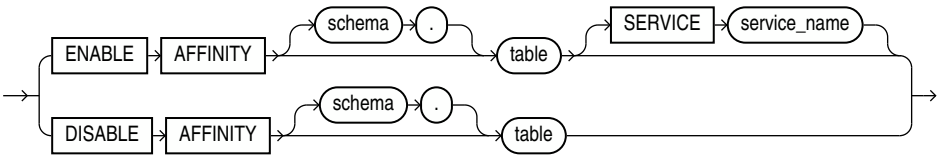
***rolling_patch_clauses*::=**



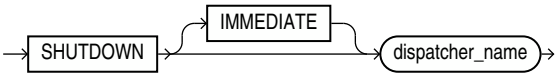
***security_clauses*::=**



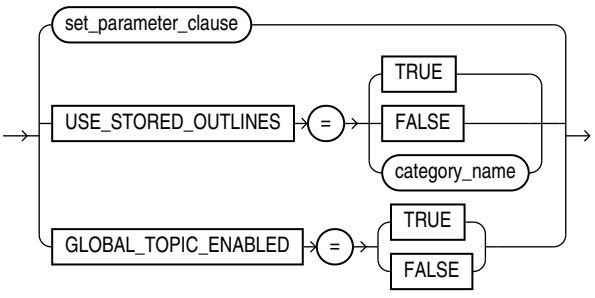
***affinity_clauses*::=**



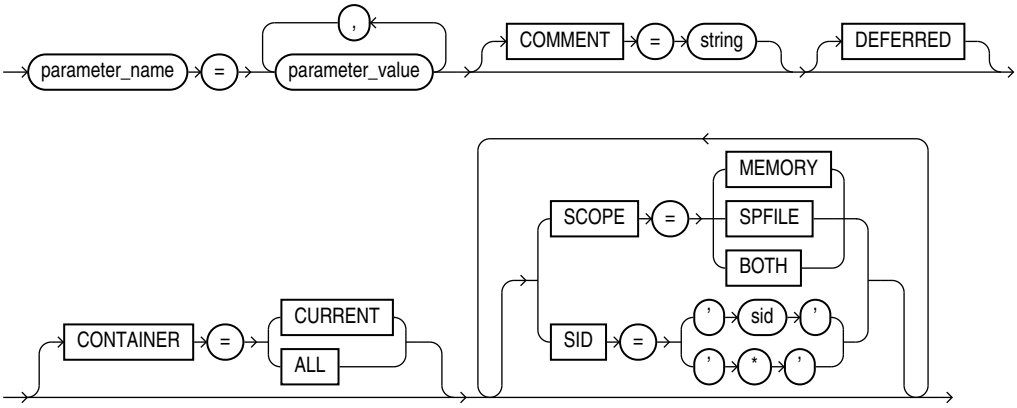
***shutdown_dispatcher_clause*::=**



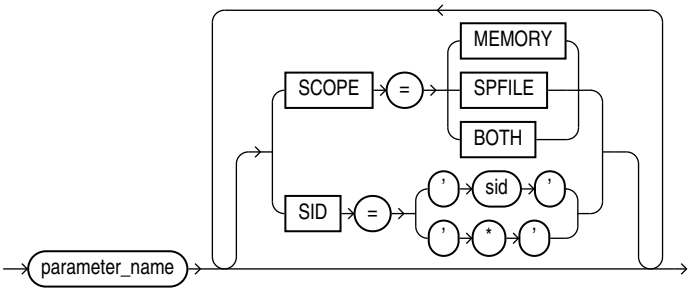
***alter_system_set_clause*::=**



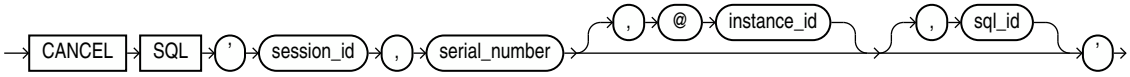
***set_parameter_clause*::=**



***alter_system_reset_clause*::=**



***cancel_sql_clause*::=**



Semantics

archive_log_clause

The *archive_log_clause* manually archives redo log files or enables or disables automatic archiving. To use this clause, your instance must have the database mounted. The database can be either open or closed unless otherwise noted.

INSTANCE Clause

This clause is relevant only if you are using Oracle Real Application Clusters (Oracle RAC). Specify the name of the instance for which you want the redo log file group to be archived. The instance name is a string of up to 80 characters. Oracle Database automatically determines the thread that is mapped to the specified instance and archives the corresponding redo log file group. If no thread is mapped to the specified instance, then Oracle Database returns an error.

SEQUENCE Clause

Specify SEQUENCE to manually archive the online redo log file group identified by the log sequence number *integer* in the specified thread. If you omit the THREAD parameter, then Oracle Database archives the specified group from the thread assigned to your instance.

CHANGE Clause

Specify CHANGE to manually archive the online redo log file group containing the redo log entry with the system change number (SCN) specified by *integer* in the specified thread. If the SCN is in the current redo log file group, then Oracle Database performs a log switch. If you omit the THREAD parameter, then Oracle Database archives the groups containing this SCN from all enabled threads.

You can use this clause only when your instance has the database open.

CURRENT Clause

Specify CURRENT to manually archive the current redo log file group of the specified thread, forcing a log switch. If you omit the THREAD parameter, then Oracle Database archives all redo log file groups from all enabled threads, including logs previous to current logs. You can specify CURRENT only when the database is open.

NOSWITCH

Specify NOSWITCH if you want to manually archive the current redo log file group without forcing a log switch. This setting is used primarily with standby databases to prevent data divergence when the primary database shuts down. Divergence implies the possibility of data loss in case of primary database failure.

You can use the NOSWITCH clause only when your instance has the database mounted but not open. If the database is open, then this operation closes the database automatically. You must then manually shut down the database before you can reopen it.

GROUP Clause

Specify GROUP to manually archive the online redo log file group with the GROUP value specified by *integer*. You can determine the GROUP value for a redo log file group by querying the dynamic performance view V$LOG. If you specify both the THREAD and GROUP parameters, then the specified redo log file group must be in the specified thread.

LOGFILE Clause

Specify LOGFILE to manually archive the online redo log file group containing the redo log file member identified by '*filename*'. If you specify both the THREAD and LOGFILE parameters, then the specified redo log file group must be in the specified thread.

If the database was mounted with a backup control file, then specify USING BACKUP CONTROLFILE to permit archiving of all online logfiles, including the current logfile.

Restriction on the LOGFILE clause

You must archive redo log file groups in the order in which they are filled. If you specify a redo log file group for archiving with the LOGFILE parameter, and earlier redo log file groups are not yet archived, then Oracle Database returns an error.

NEXT Clause

Specify NEXT to manually archive the next online redo log file group from the specified thread that is full but has not yet been archived. If you omit the THREAD parameter, then Oracle Database archives the earliest unarchived redo log file group from any enabled thread.

ALL Clause

Specify `ALL` to manually archive all online redo log file groups from the specified thread that are full but have not been archived. If you omit the `THREAD` parameter, then Oracle Database archives all full unarchived redo log file groups from all enabled threads.

TO *location* Clause

Specify `TO '`*`location`*`'` to indicate the primary location to which the redo log file groups are archived. The value of this parameter must be a fully specified file location following the conventions of your operating system. If you omit this parameter, then Oracle Database archives the redo log file group to the location specified by the initialization parameters `LOG_ARCHIVE_DEST` or `LOG_ARCHIVE_DEST_`*`n`*.

checkpoint_clause

Specify `CHECKPOINT` to explicitly force Oracle Database to perform a checkpoint, ensuring that all changes made by committed transactions are written to data files on disk. You can specify this clause only when your instance has the database open. Oracle Database does not return control to you until the checkpoint is complete.

GLOBAL

In an Oracle Real Application Clusters (Oracle RAC) environment, this setting causes Oracle Database to perform a checkpoint for all instances that have opened the database. This is the default.

LOCAL

In an Oracle RAC environment, this setting causes Oracle Database to perform a checkpoint only for the thread of redo log file groups for the instance from which you issue the statement.

> **See Also:**
>
> "Forcing a Checkpoint: Example"

check_datafiles_clause

In a distributed database system, such as an Oracle RAC environment, this clause updates an instance's SGA from the database control file to reflect information on all online data files.

- Specify `GLOBAL` to perform this synchronization for all instances that have opened the database. This is the default.
- Specify `LOCAL` to perform this synchronization only for the local instance.

Your instance should have the database open.

distributed_recov_clauses

The `DISTRIBUTED RECOVERY` clause lets you enable or disable distributed recovery. To use this clause, your instance must have the database open.

ENABLE

Specify `ENABLE` to enable distributed recovery. In a single-process environment, you must use this clause to initiate distributed recovery.

You may need to issue the `ENABLE DISTRIBUTED RECOVERY` statement more than once to recover an in-doubt transaction if the remote node involved in the transaction is not accessible. In-doubt transactions appear in the data dictionary view `DBA_2PC_PENDING`.

> **See Also:**
>
> "Enabling Distributed Recovery: Example"

DISABLE

Specify `DISABLE` to disable distributed recovery.

FLUSH SHARED_POOL Clause

The `FLUSH SHARED_POOL` clause lets you clear data from the shared pool in the system global area (SGA). The shared pool stores:

- Cached data dictionary information and
- Shared SQL and PL/SQL areas for SQL statements, stored procedures, functions, packages, and triggers.

This statement does not clear global application context information, nor does it clear shared SQL and PL/SQL areas for items that are currently being executed. You can use this clause regardless of whether your instance has the database dismounted or mounted, open or closed.

> **See Also:**
>
> "Clearing the Shared Pool: Example"

FLUSH GLOBAL CONTEXT Clause

The `FLUSH GLOBAL CONTEXT` clause lets you flush all global application context information from the shared pool in the system global area (SGA). You can use this clause regardless of whether your instance has the database dismounted or mounted, open or closed.

FLUSH BUFFER_CACHE Clause

The `FLUSH BUFFER_CACHE` clause lets you clear all data from the buffer cache in the system global area (SGA), including the `KEEP`, `RECYCLE`, and `DEFAULT` buffer pools.

Specify `LOCAL` if you only want to flush the local instance. To flush the buffer cache of all instances, specify `GLOBAL`. `GLOBAL` is the default.

> **Note:**
>
> This clause is intended for use only on a test database. Do not use this clause on a production database, because as a result of this statement, subsequent queries will have no hits, only misses.

This clause is useful if you need to measure the performance of rewritten queries or a suite of queries from identical starting points.

FLUSH FLASH_CACHE Clause

Use the `FLUSH FLASH_CACHE` clause to flush the Database Smart Flash Cache. This clause can be useful if you need to measure the performance of rewritten queries or a suite of queries from identical starting points, or if there might be corruption in the cache.

Specify `LOCAL` if you only want to flush the local instance. To flush the flash cache of all instances, specify `GLOBAL`. `GLOBAL` is the default.

FLUSH REDO Clause

Use the `FLUSH REDO` clause to flush redo data from a primary database to a standby database and to optionally wait for the flushed redo data to be applied to a physical or logical standby database.

This clause can allow a failover to be performed on the target standby database without data loss, even if the primary database is not in a zero data loss data protection mode, provided that all redo data that has been generated by the primary database can be flushed to the standby database.

The `FLUSH REDO` clause must be issued on a mounted, but not open, primary database.

target_db_name

For *`target_db_name`*, specify the `DB_UNIQUE_NAME` of the standby database that is to receive the redo data flushed from the primary database.

The value of the `LOG_ARCHIVE_DEST_`*`n`* database initialization parameter that corresponds to the target standby database must contain the `DB_UNIQUE_NAME` attribute, and the value of that attribute must match the `DB_UNIQUE_NAME` of the target standby database.

NO CONFIRM APPLY

If you specify this clause, then the `ALTER SYSTEM` statement will not complete until the standby database has received all of the flushed redo data. You must specify this clause if the target standby database is a snapshot standby database.

CONFIRM APPLY

If you specify this clause, then the `ALTER SYSTEM` statement will not complete until the target standby database has received and applied all flushed redo data. This is the default behavior unless you specify `NO CONFIRM APPLY`. You cannot specify this clause if the target standby database is a snapshot standby database.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information about the `FLUSH REDO` clause and failovers

FLUSH PASSWORDFILE_METADATA_CACHE

If the location or the name of the password file changes, you must notify the database that a change has occurred. The command `ALTER SYSTEM FLUSH PASSWORDFILE_METADATA_CACHE`

flushes the password file metadata cache stored in the SGA and informs the database that a change has occurred.

The command also flushes the cache from all the RAC instances if it is run in a cluster environment. Note the delay in propagating the change across all instances. Until the flush is fully propagated, some instances might continue to use the old password file.

end_session_clauses

The *end_session_clauses* give you several ways to end the current session.

DISCONNECT SESSION Clause

Use the DISCONNECT SESSION clause to disconnect the current session by destroying the dedicated server process (or virtual circuit if the connection was made by way of a Shared Server). To use this clause, your instance must have the database open. You must identify the session with both of the following values from the V$SESSION view:

- For *session_id*, specify the value of the SID column.
- For *serial_number*, specify the value of the SERIAL# column.

If system parameters are appropriately configured, then application failover will take effect.

- The POST_TRANSACTION setting allows ongoing transactions to complete before the session is disconnected. If the session has no ongoing transactions, then this clause has the same effect described for as KILL SESSION.
- The IMMEDIATE setting disconnects the session and recovers the entire session state immediately, without waiting for ongoing transactions to complete.
  - If you also specify POST_TRANSACTION and the session has ongoing transactions, then the IMMEDIATE keyword is ignored.
  - If you do not specify POST_TRANSACTION, or you specify POST_TRANSACTION but the session has no ongoing transactions, then this clause has the same effect as described for KILL SESSION IMMEDIATE.

> **See Also:**
>
> "Disconnecting a Session: Example"

KILL SESSION Clause

The KILL SESSION clause lets you mark a session as terminated, roll back ongoing transactions, release all session locks, and partially recover session resources. To use this clause, your instance must have the database open. Your session and the session to be terminated must be on the same instance unless you specify *integer3*.You must identify the session with the following values from the V$SESSION view:

- For *session_id*, specify the value of the SID column.
- For *serial_number*, specify the value of the SERIAL# column.
- For the optional *instance_id*, specify the ID of the instance where the target session to be killed exists. You can find the instance ID by querying the GV$ tables.

If the session is performing some activity that must be completed, such as waiting for a reply from a remote database or rolling back a transaction, then Oracle Database waits for this activity to complete, marks the session as terminated, and then returns control to you. If the

waiting lasts a minute, then Oracle Database marks the session to be terminated and returns control to you with a message that the session is marked to be terminated. The PMON background process then marks the session as terminated when the activity is complete.

Whether or not the session has an ongoing transaction, Oracle Database does not recover the entire session state until the session user issues a request to the session and receives a message that the session has been terminated.

> **See Also:**
>
> "Terminating a Session: Example"

IMMEDIATE

Specify IMMEDIATE to instruct Oracle Database to roll back ongoing transactions, release all session locks, recover the entire session state, and return control to you immediately.

Note that IMMEDIATE only returns control immediately, if TIMEOUT is not specified.

IMMEDIATE is similar to the case when the session is deleted without a modifier in that it waits until the activity completes. Once the activity completes, the full session is deleted without waiting for the session user and the connection is closed.

FORCE

FORCE is similar to IMMEDIATE except that FORCE will forcefully terminate the connection if a timeout occurs.

Example

```
ALTER SYSTEM KILL SESSION '20,1' FORCE;
```

NOREPLAY

This clause is valid if you are using Application Continuity. When connected to a service with Application Continuity enabled (that is, FAILOVER_TYPE = TRANSACTION), the session is recovered after the session fails or is killed. If you do not want to recover a session after it is terminated, then specify NOREPLAY.

TIMEOUT

Specify TIMEOUT to set the maximum amount of time (in seconds) to wait before terminating the session. It overrides the default timeout.

The current default timeout values are:

- 60 seconds when no modifier is specified
- 0 seconds when the modifier IMMEDIATE is specified
- 5 seconds when the modifier FORCE is specified

The action that occurs at TIMEOUT is different for IMMEDIATE, which marks the session for termination and FORCE , which forcefully terminates the session.

Example

```
ALTER SYSTEM KILL SESSION '20,1' TIMEOUT 20;
```

SWITCH LOGFILE Clause

The `SWITCH LOGFILE` clause lets you explicitly force Oracle Database to begin writing to a new redo log file group, regardless of whether the files in the current redo log file group are full. When you force a log switch, Oracle Database begins to perform a checkpoint but returns control to you immediately rather than when the checkpoint is complete. To use this clause, your instance must have the database open.

> **See Also:**
>
> "Forcing a Log Switch: Example"

SUSPEND | RESUME

The `SUSPEND` clause lets you suspend all I/O (data file, control file, and file header) as well as queries, in all instances, enabling you to make copies of the database without having to handle ongoing transactions.

Restrictions on SUSPEND and RESUME

`SUSPEND` and `RESUME` are subject to the following restrictions:

- Do not use this clause unless you have put the database tablespaces in hot backup mode.
- Do not terminate the session that issued the `ALTER SYSTEM SUSPEND` statement. An attempt to reconnect while the system is suspended may fail because of recursive SQL that is running during the `SYS` login.
- If you start a new instance while the system is suspended, then that new instance will not be suspended.

The `RESUME` clause lets you make the database available once again for queries and I/O.

quiesce_clauses

Use the `QUIESCE RESTRICTED` and `UNQUIESCE` clauses to put the database in and take it out of the **quiesced state**. This state enables database administrators to perform administrative operations that cannot be safely performed in the presence of concurrent transactions, queries, or PL/SQL operations.

> **Note:**
>
> The `QUIESCE RESTRICTED` clause is valid only if the Database Resource Manager is installed and only if the Resource Manager has been on continuously since database startup in any instances that have opened the database.

If multiple `QUIESCE RESTRICTED` or `UNQUIESCE` statements issue at the same time from different sessions or instances, then all but one will receive an error.

QUIESCE RESTRICTED

Specify `QUIESCE RESTRICTED` to put the database in the quiesced state. For all instances with the database open, this clause has the following effect:

- Oracle Database instructs the Database Resource Manager in all instances to prevent all inactive sessions (other than `SYS` and `SYSTEM`) from becoming active. No user other than `SYS` and `SYSTEM` can start a new transaction, a new query, a new fetch, or a new PL/SQL operation.
- Oracle Database waits for all existing transactions in all instances that were initiated by a user other than `SYS` or `SYSTEM` to finish (either commit or abort). Oracle Database also waits for all running queries, fetches, and PL/SQL procedures in all instances that were initiated by users other than `SYS` or `SYSTEM` and that are not inside transactions to finish. If a query is carried out by multiple successive OCI fetches, then Oracle Database does not wait for all fetches to finish. It waits for the current fetch to finish and then blocks the next fetch. Oracle Database also waits for all sessions (other than those of `SYS` or `SYSTEM`) that hold any shared resources (such as enqueues) to release those resources. After all these operations finish, Oracle Database places the database into quiesced state and finishes executing the `QUIESCE RESTRICTED` statement.
- If an instance is running in shared server mode, then Oracle Database instructs the Database Resource Manager to block logins (other than `SYS` or `SYSTEM`) on that instance. If an instance is running in non-shared-server mode, then Oracle Database does not impose any restrictions on user logins in that instance.

During the quiesced state, you cannot change the Resource Manager plan in any instance.

UNQUIESCE

Specify `UNQUIESCE` to take the database out of quiesced state. Doing so permits transactions, queries, fetches, and PL/SQL procedures that were initiated by users other than `SYS` or `SYSTEM` to be undertaken once again. The `UNQUIESCE` statement does not have to originate in the same session that issued the `QUIESCE RESTRICTED` statement.

rolling_migration_clauses

Use these clauses in a clustered Oracle Automatic Storage Management (Oracle ASM) environment to migrate one node at a time to a different Oracle ASM version without affecting the overall availability of the Oracle ASM cluster or the database clusters using Oracle ASM for storage.

START ROLLING MIGRATION

When starting rolling upgrade, for *`ASM_version`*, you must specify the following string:

```
'<version_num>, <release_num>, <update_num>,<port_release_num>,<port_update_num>'
```

`ASM_version` must be equal to or greater than 11.1.0.0.0. The surrounding single quotation marks are required. Oracle ASM first verifies that the current release is compatible for migration to the specified release, and then goes into limited functionality mode. Oracle ASM then determines whether any rebalance operations are under way anywhere in the cluster. If there are any such operations, then the statement fails and must be reissued after the rebalance operations are complete.

Rolling upgrade mode is a cluster-wide In-Memory persistent state. The cluster continues to be in this state until there is at least one Oracle ASM instance running in the cluster. Any new instance joining the cluster switches to migration mode immediately upon startup. If all the instances in the cluster terminate, then subsequent startup of any Oracle ASM instance will not be in rolling upgrade mode until you reissue this statement to restart rolling upgrade of the Oracle ASM instances.

STOP ROLLING MIGRATION

Use this clause to stop rolling upgrade and bring the cluster back into normal operation. Specify this clause only after all instances in the cluster have migrated to the same software version. The statement will fail if the cluster is not in rolling upgrade mode.

When you specify this clause, the Oracle ASM instance validates that all the members of the cluster are at the same software version, takes the instance out of rolling upgrade mode, and returns to full functionality of the Oracle ASM cluster. If any rebalance operations are pending because disks have gone offline, then those operations are restarted if the `ASM_POWER_LIMIT` parameter would not be violated by such a restart.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for more information about rolling upgrade

rolling_patch_clauses

Use these clauses in a clustered Oracle Automatic Storage Management (Oracle ASM) environment to update one node at a time to the latest patch level without affecting the overall availability of the Oracle ASM cluster or the database clusters using Oracle ASM for storage.

START ROLLING PATCH

Use this clause to start the rolling patch operation. Oracle ASM first verifies that all live nodes in the cluster are at the same version, and then goes into rolling patch mode, which is a cluster-wide In-Memory persistent state. The cluster continues to be in this state until all live nodes have been patched to the latest patch level.

Any nodes that are down during this operation are not patched. This does not affect the success of the rolling patch operation. However, you must patch these nodes before they are started. Otherwise, they will not be allowed to join the cluster.

STOP ROLLING PATCH

use this clause to stop the rolling patch operation and bring the cluster back into normal operation. Specify this clause only after all live nodes in the cluster have been patched to the latest patch level. The statement will fail if the cluster is not in rolling patch mode.

When you specify this clause, the Oracle ASM instance validates that all members of the cluster are at the same patch level, takes the instance out of rolling patch mode, and returns full functionality of the Oracle ASM cluster. If any members of the cluster are not at the latest patch level, then this operation fails and the cluster goes into limited functionality mode.

The following queries display information about rolling patches. In order to run these queries, you must be connected to the Oracle ASM instance in the Grid home, and the Grid Infrastructure home must be configured with the Oracle Clusterware option for an Oracle RAC environment.

- You can determine whether a cluster is in rolling patch mode with the following query:

  ```
  SELECT SYS_CONTEXT('SYS_CLUSTER_PROPERTIES', 'CLUSTER_STATE') FROM DUAL;
  ```

- You can determine the patch level of a cluster with the following query:

  ```
  SELECT SYS_CONTEXT('SYS_CLUSTER_PROPERTIES', 'CURRENT_PATCHLVL') FROM DUAL;
  ```

- You can display a list of patches applied on the Oracle ASM instance, by querying the `V$PATCHES` dynamic performance view. Refer to *Oracle Database Reference* for more information.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for more information about rolling patches

security_clauses

The *security_clauses* let you control access to the instance. They also allow you to enable or disable access to the encrypted data in the instance.

RESTRICTED SESSION

The RESTRICTED SESSION clause lets you restrict logon to Oracle Database. You can use this clause regardless of whether your instance has the database dismounted or mounted, open or closed.

- Specify ENABLE to allow only users with RESTRICTED SESSION system privilege to log on to Oracle Database. Existing sessions are not terminated.

  This clause applies only to the current instance. Therefore, in an Oracle RAC environment, authorized users without the RESTRICTED SESSION system privilege can still access the database by way of other instances.
- Specify DISABLE to reverse the effect of the ENABLE RESTRICTED SESSION clause, allowing all users with CREATE SESSION system privilege to log on to Oracle Database. This is the default.

> **See Also:**
>
> - "Restricting Sessions: Example"
> - The description of the CREATE TABLE "*encryption_spec* " for information on using that feature to encrypt table columns
> - "Establishing a Wallet and Encryption Key: Examples"

affinity_clauses

Use the affinity clauses to enable data-dependent routing to provide cache affinity on a RAC database. The affinity logically partitions data across RAC instances so that a distinct subset of data is assigned to each instance. When data is accessed with a sharding key, the request will be routed to the instance that holds the corresponding subset of data. The benefits of affinity are:

- Sharded access for shard-aware applications and transparency for non-sharded applications
- Better cache utilization and reduced block pings

shutdown_dispatcher_clause

The SHUTDOWN clause is relevant only if your system is using the shared server architecture of Oracle Database. It shuts down a dispatcher identified by *dispatcher_name*.

> **Note:**
>
> Do not confuse this clause with the SQL*Plus command `SHUTDOWN`, which is used to shut down the entire database.

The *`dispatcher_name`* must be a string of the form '`D`*`xxx`*', where *`xxx`* indicates the number of the dispatcher. For a listing of dispatcher names, query the `NAME` column of the `V$DISPATCHER` dynamic performance view.

- If you specify `IMMEDIATE`, then the dispatcher stops accepting new connections immediately and Oracle Database terminates all existing connections through that dispatcher. After all sessions are cleaned up, the dispatcher process shuts down.
- If you do not specify `IMMEDIATE`, then the dispatcher stops accepting new connections immediately but waits for all its users to disconnect and for all its database links to terminate. Then it shuts down.

REGISTER Clause

Specify `REGISTER` to instruct the `PMON` background process to register the instance with the listeners immediately. If you do not specify this clause, then registration of the instance does not occur until the next time `PMON` executes the discovery routine. As a result, clients may not be able to access the services for as long as 60 seconds after the listener is started.

> **See Also:**
>
> *Oracle Database Concepts* and *Oracle Database Net Services Administrator's Guide* for information on the `PMON` background process and listeners

alter_system_set_clause

This clause allows you to change parameter values. The *`set_parameter_clause`* allows you to change the value of a specified initialization parameter. The `USE_STORED_OUTLINES` and `GLOBAL_TOPIC_ENABLED` clauses allow you to change the value of those system parameters.

set_parameter_clause

You can change the value of many initialization parameters for the current instance, whether you have started the database with a traditional plain-text parameter file (pfile) or with a server parameter file (spfile). *Oracle Database Reference* indicates these parameters in the "Modifiable" category of each parameter description. If you are using a pfile, then the change will persist only for the duration of the instance. However, if you have started the database with an spfile, then you can change the value of the parameter in the spfile itself, so that the new value will occur in subsequent instances.

Oracle Database Reference documents all initialization parameters in full. The parameters fall into three categories:

- **Basic parameters:** Database administrators should be familiar with and consider the setting for all of the basic parameters.
- **Functional categories:** Oracle Database Reference also lists the initialization parameters by their functional category.

- **Alphabetical listing:** The Table of Contents of *Oracle Database Reference* contains all initialization parameters in alphabetical order.

The ability to change initialization parameter values depends on whether you have started up the database with a traditional plain-text initialization parameter file (pfile) or with a server parameter file (spfile). To determine whether you can change the value of a particular parameter, query the `ISSYS_MODIFIABLE` column of the `V$PARAMETER` dynamic performance view.

If you want to enforce case on parameter values that are string literals, you must enclose them within single quotes.

You can enforce the minimum password length for database user accounts across the entire CDB or individual PDBs by setting the `MANDATORY_USER_PROFILE` parameter in the `init.ora` file.

Example

This statement sets the `MANDATORY_USER_PROFILE` parameter to the mandatory profile `c##cdb_profile` for all the PDBs in the CDB:

```
ALTER SYSTEM SET MANDATORY_USER_PROFILE=c##cdb_profile;
```

Only a common user who has been commonly granted the `ALTER SYSTEM` privilege or has the`SYSDBA` administrative privilege can modify the `MANDTORY_USER_PROFILE` in the `init.ora` file.

> **See Also:**
>
> - CREATE PROFILE
> - Managing Security for Oracle Databases

When setting a parameter value, you can specify additional settings as follows:

COMMENT

The `COMMENT` clause lets you associate a comment string with this change in the value of the parameter. The comment string cannot contain control characters or a line break. If you also specify `SPFILE`, then this comment will appear in the parameter file to indicate the most recent change made to this parameter.

DEFERRED

The `DEFERRED` keyword sets or modifies the value of the parameter for future sessions that connect to the database. Current sessions retain the old value.

You must specify `DEFERRED` if the value of the `ISSYS_MODIFIABLE` column of `V$PARAMETER` for this parameter is `DEFERRED`. If the value of that column is `IMMEDIATE`, then the `DEFERRED` keyword in this clause is optional. If the value of that column is `FALSE`, then you cannot specify `DEFERRED` in this `ALTER SYSTEM` statement.

> **See Also:**
>
> *Oracle Database Reference* for information on the `V$PARAMETER` dynamic performance view

CONTAINER

You can specify the `CONTAINER` clause when you set a parameter value in a CDB. A CDB uses an inheritance model for initialization parameters in which PDBs inherit initialization parameter values from the root. In this case, inheritance means that the value of a particular parameter in the root applies to a particular PDB.

A PDB can override the root's setting for some parameters, which means that a PDB has an inheritance property for each initialization parameter that is either true or false. The inheritance property is true for a parameter when the PDB inherits the root's value for the parameter. The inheritance property is false for a parameter when the PDB does not inherit the root's value for the parameter.

The inheritance property for some parameters must be true. For other parameters, you can change the inheritance property by running the `ALTER SYSTEM SET` statement to set the parameter when the current container is the PDB. If `ISPDB_MODIFIABLE` is `TRUE` for an initialization parameter in the `V$SYSTEM_PARAMETER` view, then the inheritance property can be false for the parameter.

- If you specify `CONTAINER = ALL`, then the parameter setting applies to all containers in the CDB, including the root and all of the PDBs. The current container must be the root.

  Specifying `ALL` sets the inheritance property to true for the parameter in all PDBs.
- If you specify `CONTAINER = CURRENT`, then the parameter setting applies only to the current container. When the current container is the root, the parameter setting applies to the root and to any PDB with an inheritance property of true for the parameter.

If you omit this clause, then `CONTAINER = CURRENT` is the default.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information on modifying parameters in a CDB

SCOPE

The `SCOPE` clause lets you specify when the change takes effect. The behavior of this clause depends on whether you are connected to a non-CDB, a CDB root, or a PDB.

When you issue the ALTER SYSTEM statement while connected to a non-CDB or a CDB root, the scope depends on whether you started up the database using a traditional plain-text parameter file (pfile) or server parameter file (spfile).

- `MEMORY` indicates that the change is made in memory, takes effect immediately, and persists until the database is shut down. If you started up the database using a parameter file (pfile), then this is the only scope you can specify.

  Note that `MEMORY` makes changes in memory of all the instances and overwrites values set individually on the instance.

- SPFILE indicates that the change is made in the server parameter file. The new setting takes effect when the database is next shut down and started up again. You must specify SPFILE when changing the value of a static parameter that is described as not modifiable in *Oracle Database Reference*.

  Note that SPFILE makes no changes in memory, which means that the instance parameter set individually on the instance takes precedence over global.

- BOTH indicates that the change is made in memory and in the server parameter file. The new setting takes effect immediately and persists after the database is shut down and started up again.

  Note that BOTH makes changes in memory of all the instances and overwrites values set individually on the instance, until the instance is restarted. When the instance is restarted, the spfile is read and then the instance parameter takes precedence.

If a server parameter file was used to start up the database, then BOTH is the default. If a parameter file was used to start up the database, then MEMORY is the default, as well as the only scope you can specify.

When you issue the ALTER SYSTEM statement while connected to a PDB, you can modify only initialization parameters for which the ISPDB_MODIFIABLE column is TRUE in the V$SYSTEM_PARAMETER view. The initialization parameter value takes effect only for the PDB. For any initialization parameter that is not set explicitly for a PDB, the PDB inherits the CDB root's parameter value.

- MEMORY indicates that the change is made in memory and takes effect immediately in the PDB. The setting reverts to the value set in the CDB root in the any of the following cases:
  - An ALTER SYSTEM SET statement sets the value of the parameter in the root with SCOPE equal to BOTH or MEMORY, and the PDB is closed and reopened. The parameter value in the PDB is not changed if SCOPE is equal to SPFILE, and the PDB is closed and reopened.
  - The PDB is closed and reopened.
  - The CDB is shut down and reopened.
- SPFILE indicates that the change is made for the PDB and stored persistently. The new setting affects only the PDB and takes effect in either of the following cases:
  - The PDB is closed and reopened.
  - The CDB is shut down and reopened.
- BOTH indicates that the change is made in memory, made for the PDB, and stored persistently. The new setting takes effect immediately in the PDB and persists after the PDB is closed and reopened or the CDB is shut down and reopened. The new setting affects only the PDB.

When a PDB is unplugged from a CDB, the values of the initialization parameters that were specified for the PDB with SCOPE=BOTH or SCOPE=SPFILE are added to the PDB's XML metadata file. These values are restored for the PDB when it is plugged in to a CDB.

> **Note:**
>
> Oracle may internally adjust the parameter value passed in `ALTER SYSTEM SET` before it is set in memory or the spfile. For example, if you input a non-prime number when the paramenter value should be a prime number, Oracle will adjust the value to the next prime number. You can query the parameter value from parameter views `V$PARAMETER`, `V$SYSTEM_PARAMETER`, and `V$SPPARAMETER`.

SID

The `SID` clause lets you specify the SID of the instance where the value will take effect.

- Specify `SID = '*'` if you want Oracle Database to change the value of the parameter for all instances that do not already have an explicit setting for this parameter.
- Specify `SID = 'sid'` if you want Oracle Database to change the value of the parameter only for the instance *sid*. This setting takes precedence over previous and subsequent `ALTER SYSTEM SET` statements that specify `SID = '*'`.

If you do not specify this clause, then:

- If the instance was started up with a pfile (traditional plain-text initialization parameter file), then Oracle Database assumes the SID of the current instance.
- If the instance was started up with an spfile (server parameter file), then Oracle Database assumes `SID = '*'`.

If you specify an instance other than the current instance, then Oracle Database sends a message to that instance to change the parameter value in the memory of that instance.

USE_STORED_OUTLINES Clause

> **Note:**
>
> Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. Refer to *Oracle Database SQL Tuning Guide* for more information about SQL plan management.

`USE_STORED_OUTLINES` is a system parameter, not an initialization parameter. You cannot set it in a pfile or spfile, but you can set it with an `ALTER SYSTEM` statement. This parameter determines whether the optimizer will use stored public outlines to generate execution plans.

- `TRUE` causes the optimizer to use outlines stored in the `DEFAULT` category when compiling requests.
- `FALSE` specifies that the optimizer should not use stored outlines. This is the default.
- *`category_name`* causes the optimizer to use outlines stored in the *`category_name`* category when compiling requests.

GLOBAL_TOPIC_ENABLED

`GLOBAL_TOPIC_ENABLED` is a system parameter, not an initialization parameter. You cannot set it in a pfile or spfile, but you can set it with an `ALTER SYSTEM` statement. If `GLOBAL_TOPIC_ENABLED`

= TRUE when a queue table is created, altered, or dropped, then the corresponding Lightweight Directory Access Protocol (LDAP) entry is also created, altered or dropped.

The parameter works the same way for the Java Message Service (JMS). If a database has been configured to use LDAP and the GLOBAL_TOPIC_ENABLED parameter has been set to TRUE, then all JMS queues and topics are automatically registered with the LDAP server when they are created. The administrator can also create aliases to the queues and topics registered in LDAP. Queues and topics that are registered in LDAP can be looked up through JNDI using the name or alias of the queue or topic.

Shared Server Parameters

When you start your instance, Oracle Database creates shared server processes and dispatcher processes for the shared server architecture based on the values of the SHARED_SERVERS and DISPATCHERS initialization parameters. You can also set the SHARED_SERVERS and DISPATCHERS parameters with ALTER SYSTEM to perform one of the following operations while the instance is running:

- Create additional shared server processes by increasing the minimum number of shared server processes.
- Terminate existing shared server processes after their current calls finish processing.
- Create more dispatcher processes for a specific protocol, up to a maximum across all protocols specified by the initialization parameter MAX_DISPATCHERS.
- Terminate existing dispatcher processes for a specific protocol after their current user processes disconnect from the instance.

See Also:

- *Oracle Real Application Clusters Administration and Deployment Guide* for information on setting parameter values for an individual instance in an Oracle Real Application Clusters environment
- The following examples of using the ALTER SYSTEM statement: "Changing Licensing Parameters: Examples", "Enabling Query Rewrite: Example", "Enabling Resource Limits: Example", "Shared Server Parameters", and "Changing Shared Server Settings: Examples"

alter_system_reset_clause

This clause lets you reset an initialization parameter.

The semantics of this clause are similar to the *set_parameter_clause*, except instead of changing the value of an initialization parameter, this clause removes the setting of an initialization parameter. Refer to the set_parameter_clause to learn about the parameters you can reset, and for the full semantics of the SCOPE and SID clauses.

RELOCATE CLIENT

This clause is valid only if you are using Oracle Flex ASM. You must issue this clause from within an Oracle ASM instance, not from a normal database instance.

Use this clause to relocate the specified client to the least loaded Oracle ASM instance. When you issue this clause, the connection to the client is terminated and the client fails over to the

least loaded instance. If the client is currently connected to the least loaded instance, then the connection to the client is terminated and the client fails over to that same instance.

For *client_id*, specify a string of the following form enclosed in single quotation marks:

instance_name:*db_name*

where *instance_name* is the identifier for the client and *db_name* is the database name for the client. You can find these values by querying the INSTANCE_NAME and DB_NAME columns of the V$ASM_CLIENT dynamic performance view.

> **See Also:**
>
> - *Oracle Automatic Storage Management Administrator's Guide* for more information on managing Oracle Flex ASM
> - *Oracle Database Reference* for more information on the V$ASM_CLIENT dynamic performance view

cancel_sql_clause

Use this clause to terminate a SQL operation that is consuming excessive resources, including parallel servers. You must provide the session id and the session serial number of the session whose active SQL statement you want to cancel. If the session is idle (no actively running SQL statement), the next SQL statement will be canceled. To avoid the next SQL statement from getting canceled, specify the sql_id in the arguments to identify the SQL statement to be canceled.

- session_id is required and stands for the session identifier.
- serial_number is required and stands for the serial number of the session.
- instance_id is optional. If this argument is omitted, the instance id of the current session is used.
- sql_id is optional. If this argument is specified, the sql_id will be matched with the actively-running SQL statement in the session before terminating the SQL. If the session is executing a SQL statement other than the one specified in the sql_id argument, an error is raised.

Examples

Archiving Redo Logs Manually: Examples

The following statement manually archives the redo log file group containing the redo log entry with the SCN 9356083:

```
ALTER SYSTEM ARCHIVE LOG CHANGE 9356083;
```

The following statement manually archives the redo log file group containing a member named 'diskl:log6.log' to an archived redo log file in the location 'diska:[arch$]':

```
ALTER SYSTEM ARCHIVE LOG
    LOGFILE 'diskl:log6.log'
    TO 'diska:[arch$]';
```

Enabling Query Rewrite: Example

This statement enables query rewrite in all sessions for all materialized views for which query rewrite has not been explicitly disabled:

```
ALTER SYSTEM SET QUERY_REWRITE_ENABLED = TRUE;
```

Restricting Sessions: Example

You might want to restrict sessions if you are performing application maintenance and you want only application developers with `RESTRICTED SESSION` system privilege to log on. To restrict sessions, issue the following statement:

```
ALTER SYSTEM
   ENABLE RESTRICTED SESSION;
```

You can then terminate any existing sessions using the `KILL SESSION` clause of the `ALTER SYSTEM` statement.

After performing maintenance on your application, issue the following statement to allow any user with `CREATE SESSION` system privilege to log on:

```
ALTER SYSTEM
   DISABLE RESTRICTED SESSION;
```

Establishing a Wallet and Encryption Key: Examples

The following statements load information from the server wallet into memory and set the Transparent Data Encryption master key:

```
ALTER SYSTEM SET ENCRYPTION WALLET OPEN IDENTIFIED BY "password";
ALTER SYSTEM SET ENCRYPTION KEY IDENTIFIED BY "password";
```

These statements assume that you have initialized the security module and created a wallet with *password*.

Closing a Wallet: Examples

The following statement removes password-based wallet information from memory:

```
ALTER SYSTEM SET ENCRYPTION WALLET CLOSE IDENTIFIED BY "password";
```

The following statement removes password-based wallet information and auto-login information, if present, from memory:

```
ALTER SYSTEM SET ENCRYPTION WALLET CLOSE;
```

Clearing the Shared Pool: Example

You might want to clear the shared pool before beginning performance analysis. To clear the shared pool, issue the following statement:

```
ALTER SYSTEM FLUSH SHARED_POOL;
```

Forcing a Checkpoint: Example

The following statement forces a checkpoint:

```
ALTER SYSTEM CHECKPOINT;
```

Enabling Resource Limits: Example

This `ALTER SYSTEM` statement dynamically enables resource limits:

```
ALTER SYSTEM SET RESOURCE_LIMIT = TRUE;
```

Changing Shared Server Settings: Examples

The following statement changes the minimum number of shared server processes to 25:

```
ALTER SYSTEM SET SHARED_SERVERS = 25;
```

If there are currently fewer than 25 shared server processes, then Oracle Database creates more. If there are currently more than 25, then Oracle Database terminates some of them when they are finished processing their current calls if the load could be managed by the remaining 25.

The following statement dynamically changes the number of dispatcher processes for the TCP/IP protocol to 5 and the number of dispatcher processes for the ipc protocol to 10:

```
ALTER SYSTEM
   SET DISPATCHERS =
      '(INDEX=0)(PROTOCOL=TCP)(DISPATCHERS=5)',
      '(INDEX=1)(PROTOCOL=ipc)(DISPATCHERS=10)';
```

If there are currently fewer than 5 dispatcher processes for TCP, then Oracle Database creates new ones. If there are currently more than 5, then Oracle Database terminates some of them after the connected users disconnect.

If there are currently fewer than 10 dispatcher processes for ipc, then Oracle Database creates new ones. If there are currently more than 10, then Oracle Database terminates some of them after the connected users disconnect.

If there are currently existing dispatchers for another protocol, then the preceding statement does not affect the number of dispatchers for that protocol.

Changing Licensing Parameters: Examples

The following statement dynamically changes the limit on sessions for your instance to 64 and the warning threshold for sessions on your instance to 54:

```
ALTER SYSTEM
   SET LICENSE_MAX_SESSIONS = 64
   LICENSE_SESSIONS_WARNING = 54;
```

If the number of sessions reaches 54, then Oracle Database writes a warning message to the `ALERT` file for each subsequent session. Also, users with `RESTRICTED SESSION` system privilege receive warning messages when they begin subsequent sessions.

If the number of sessions reaches 64, then only users with `RESTRICTED SESSION` system privilege can begin new sessions until the number of sessions falls below 64 again.

The following statement dynamically disables the limit for sessions on your instance. After you issue this statement, Oracle Database no longer limits the number of sessions on your instance.

```
ALTER SYSTEM SET LICENSE_MAX_SESSIONS = 0;
```

The following statement dynamically changes the limit on the number of users in the database to 200. After you issue the preceding statement, Oracle Database prevents the number of users in the database from exceeding 200.

```
ALTER SYSTEM SET LICENSE_MAX_USERS = 200;
```

Forcing a Log Switch: Example

You might want to force a log switch to drop or rename the current redo log file group or one of its members, because you cannot drop or rename a file while Oracle Database is writing to it.

The forced log switch affects only the redo log thread of your instance. The following statement forces a log switch:

```
ALTER SYSTEM SWITCH LOGFILE;
```

Enabling Distributed Recovery: Example

The following statement enables distributed recovery:

```
ALTER SYSTEM ENABLE DISTRIBUTED RECOVERY;
```

You might want to disable distributed recovery for demonstration or testing purposes. You can disable distributed recovery in both single-process and multiprocess mode with the following statement:

```
ALTER SYSTEM DISABLE DISTRIBUTED RECOVERY;
```

When your demonstration or testing is complete, you can then enable distributed recovery again by issuing an `ALTER SYSTEM` statement with the `ENABLE DISTRIBUTED RECOVERY` clause.

Terminating a Session: Example

You might want to terminate the session of a user that is holding resources needed by other users. The user receives an error message indicating that the session has been terminated. That user can no longer make calls to the database without beginning a new session. Consider this data from the `V$SESSION` dynamic performance table, when the users `SYS` and `oe` both have open sessions:

```
SELECT sid, serial#, username
   FROM V$SESSION;

       SID    SERIAL# USERNAME
---------- ---------- ------------------------------
        29         85 SYS
        33          1
        35          8
        39         23 OE
        40          1
. . .
```

The following statement terminates the session of the user `scott` using the `SID` and `SERIAL#` values from `V$SESSION`:

```
ALTER SYSTEM KILL SESSION '39, 23';
```

Disconnecting a Session: Example

The following statement disconnects user `scott`'s session, using the `SID` and `SERIAL#` values from `V$SESSION`:

```
ALTER SYSTEM DISCONNECT SESSION '13, 8' POST_TRANSACTION;
```

ALTER TABLE

Purpose

Use the `ALTER TABLE` statement to alter the definition of a nonpartitioned table, a partitioned table, a table partition, or a table subpartition. For object tables or relational tables with object columns, use `ALTER TABLE` to convert the table to the latest definition of its referenced type after the type has been altered.

> **Note:**
>
> Oracle recommends that you use the `ALTER MATERIALIZED VIEW LOG` statement, rather than `ALTER TABLE`, whenever possible for operations on materialized view log tables.

> **See Also:**
>
> - CREATE TABLE for information on creating tables
> - *Oracle Text Reference* for information on `ALTER TABLE` statements in conjunction with Oracle Text

Prerequisites

The table must be in your own schema, or you must have `ALTER` object privilege on the table, or you must have `ALTER ANY TABLE` system privilege.

Additional Prerequisites for Partitioning Operations

If you are not the owner of the table, then you need the `DROP ANY TABLE` privilege in order to use the *`d_table_partition`* or *`truncate_table_partition`* clause.

You must also have space quota in the tablespace in which space is to be acquired in order to use the *`add_table_partition`*, *`modify_table_partition`*, *`move_table_partition`*, and *`split_table_partition`* clauses.

When a partitioning operation cascades to reference-partitioned child tables, privileges are not required on the reference-partitioned child tables.

When using the *`exchange_partition_subpart`* clause, if the table data being exchanged contains an identity column and you are not the owner of both tables involved in the exchange, then you must have the `ALTER ANY SEQUENCE` system privilege.

You cannot partition a non-partitioned table that has an object type.

Additional Prerequisites for Constraints and Triggers

To enable a unique or primary key constraint, you must have the privileges necessary to create an index on the table. You need these privileges because Oracle Database creates an index on the columns of the unique or primary key in the schema containing the table.

To enable or disable triggers, the triggers must be in your schema or you must have the `ALTER ANY TRIGGER` system privilege.

> **See Also:**
>
> CREATE INDEX for information on the privileges needed to create indexes

Additional Prerequisites When Using Object Types

To use an object type in a column definition when modifying a table, either that object must belong to the same schema as the table being altered, or you must have either the `EXECUTE ANY TYPE` system privilege or the `EXECUTE` object privilege for the object type.

Additional Prerequisites for Flashback Data Archive Operations

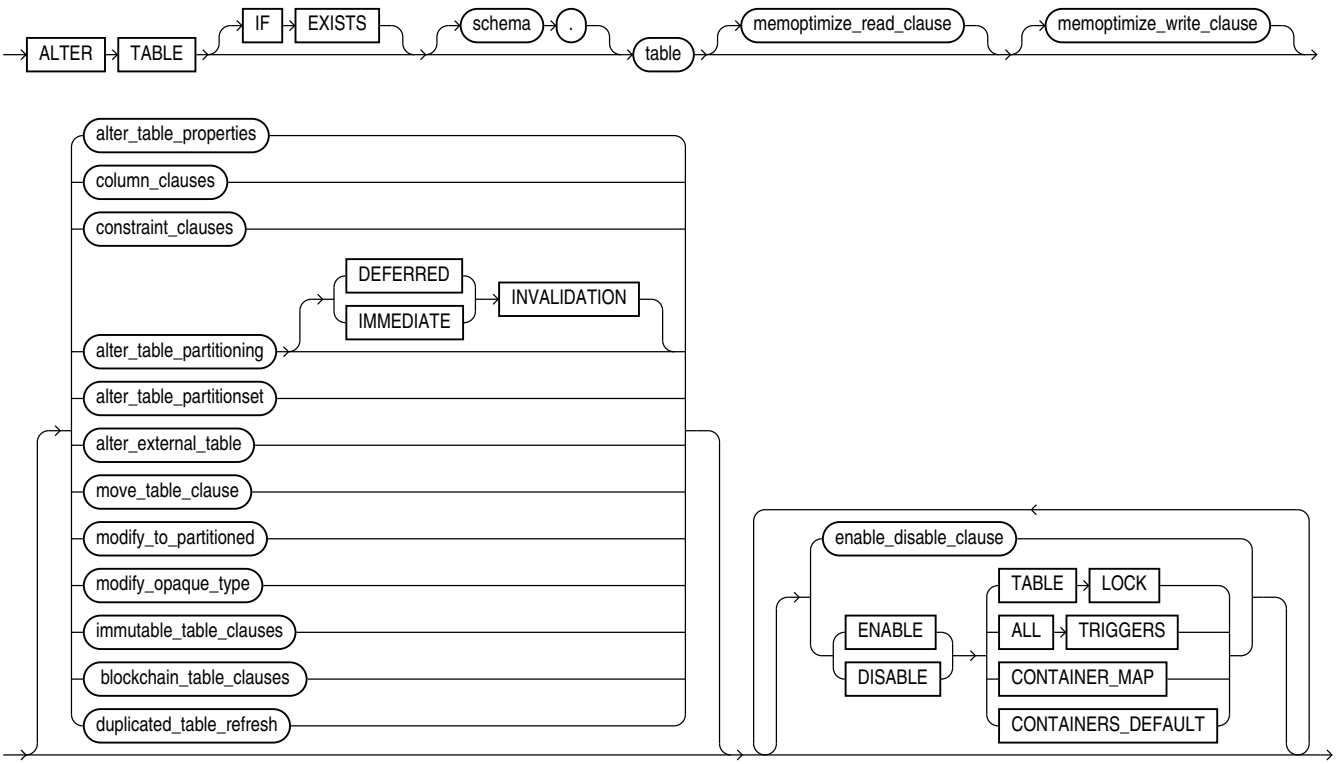
To use the *`flashback_archive_clause`* to *enable* historical tracking for the table, you must have the `FLASHBACK ARCHIVE` object privilege on the flashback data archive that will contain the historical data. To use the *`flashback_archive_clause`* to *disable* historical tracking for the table, you must have the `FLASHBACK ARCHIVE ADMINSTER` system privilege or you must be logged in as `SYSDBA`.

Additional Prerequisite for Referring to Editioned Objects

To specify an edition in the *`evaluation_edition_clause`* or the *`unusable_editions_clause`*, you must have the `USE` privilege on the edition.

Syntax

***alter_table*::=**



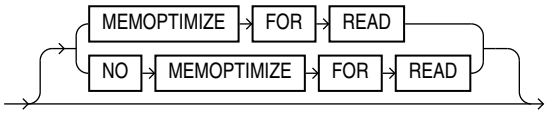
> **Note:**
>
> You must specify some clause after *`table`*. None of the clauses after *`table`* are required, but you must specify at least one of them.

Groups of ALTER TABLE syntax:

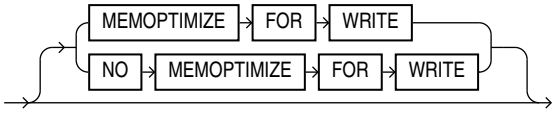
- ***alter_table_properties*::=**
- ***column_clauses*::=**
- ***constraint_clauses*::=**
- ***alter_table_partitioning*::=**
- ***alter_table_partitionset*::=**
- ***alter_external_table*::=**
- ***move_table_clause*::=**
- ***modify_to_partitioned*::=**
- ***modify_opaque_type*::=**
- **immutable_table_clauses**
- **blockchain_table_clauses**
- ***duplicated_table_refresh*::=**
- ***enable_disable_clause*::=**

After each clause you will find links to its component subclauses.

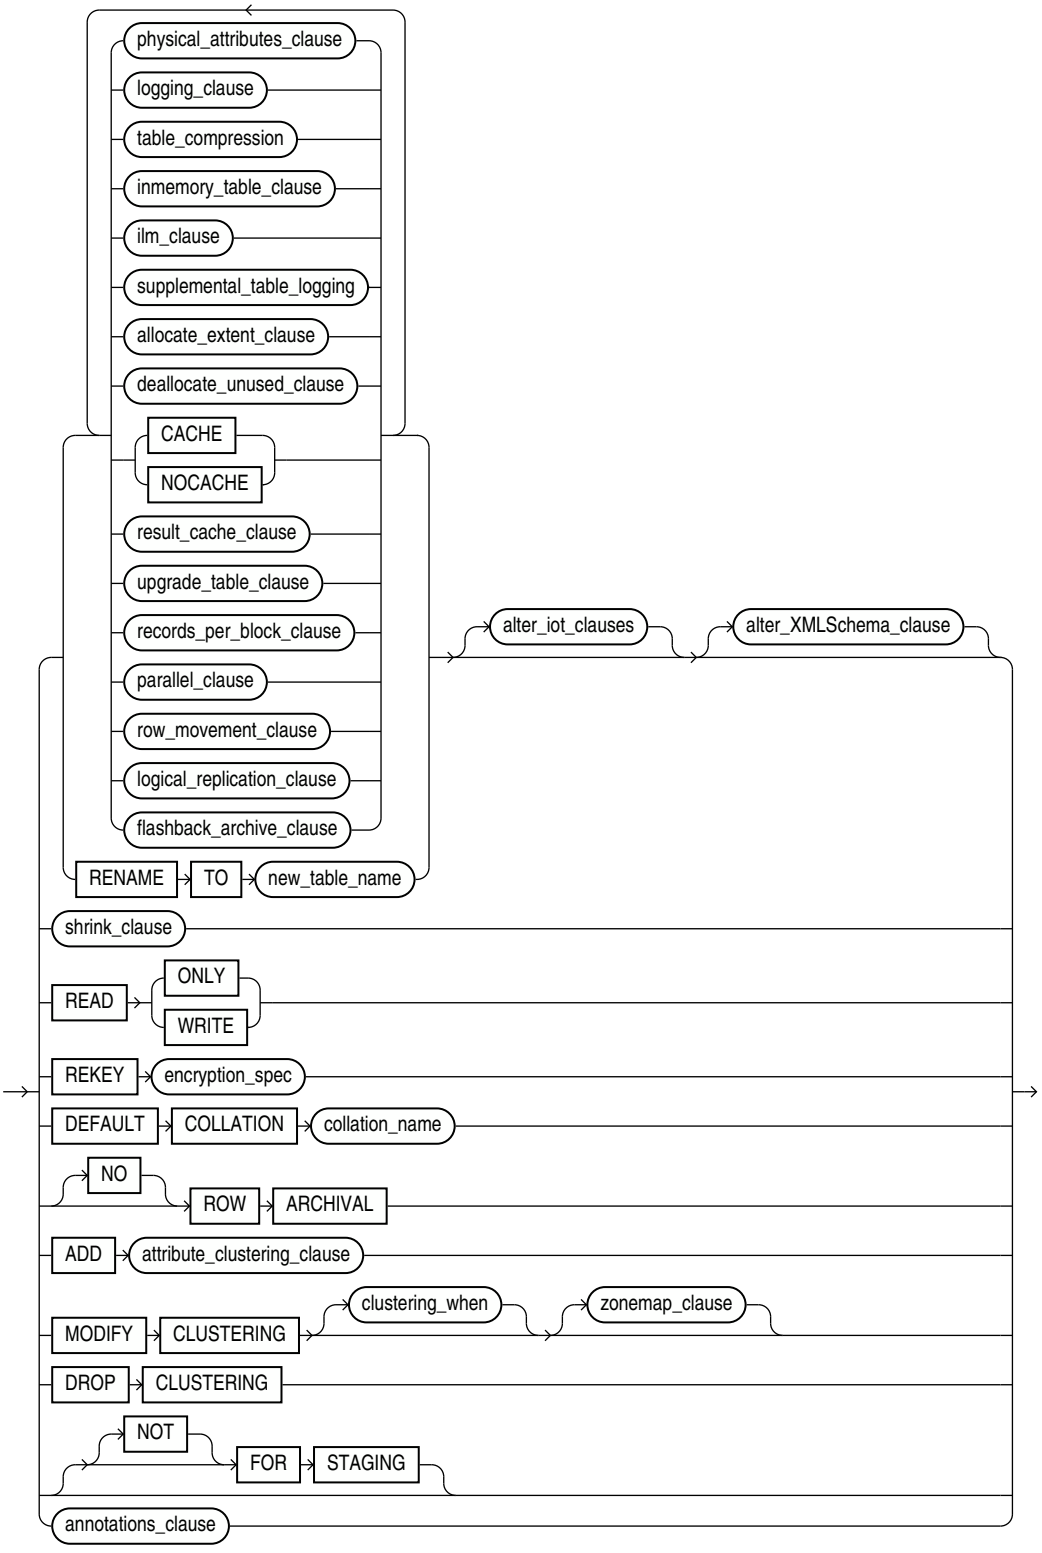
***memoptimize_read_clause*::=**



memoptimize_write_clause



***alter_table_properties*::=**



> **Note:**
>
> If you specify the `MODIFY CLUSTERING` clause, then you must specify at least one of the clauses *clustering_when* or *zonemap_clause*.

Semantics

Many clauses of the `ALTER TABLE` statement have the same functionality they have in a `CREATE TABLE` statement. For more information on such clauses, see CREATE TABLE.

> **Note:**
>
> Operations performed by the `ALTER TABLE` statement can cause Oracle Database to invalidate procedures and stored functions that access the table. For information on how and when the database invalidates such objects, see *Oracle Database Development Guide*.

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

schema

Specify the schema containing the table. If you omit *`schema`*, then Oracle Database assumes the table is in your own schema.

table

Specify the name of the table to be altered.

> **Note:**
>
> If you alter a table that is a master table for one or more materialized views, then Oracle Database marks the materialized views `INVALID`. Invalid materialized views cannot be used by query rewrite and cannot be refreshed. For information on revalidating a materialized view, see ALTER MATERIALIZED VIEW .

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for more information on materialized views in general

Restrictions on Altering Temporary Tables

You can modify, drop columns from, or rename a temporary table. However, for a temporary table you cannot:

- Add columns of nested table type. You can add columns of other types.
- Specify referential integrity (foreign key) constraints for an added or modified column.
- Specify the following clauses of the *`LOB_storage_clause`* for an added or modified LOB column: `TABLESPACE`, *`storage_clause`*, *`logging_clause`*, *`allocate_extent_clause`*, or *`deallocate_unused_clause`*.
- Specify the *`physical_attributes_clause`*, *`nested_table_col_properties`*, *`parallel_clause`*, *`allocate_extent_clause`*, *`deallocate_unused_clause`*, or any of the index-organized table clauses.

- Exchange partitions between a partition and a temporary table.
- Specify the *logging_clause*.
- Specify MOVE.
- Add an INVISIBLE column or modify an existing column to be INVISIBLE.

Restrictions on Altering External Tables

You can add, drop, or modify the columns of an external table. However, for an external table you cannot:

- Add a LONG, LOB, or object type column or change the data type of an external table column to any of these data types.
- Modify the storage parameters of an external table.
- Specify the *logging_clause*.
- Specify MOVE.
- Add an INVISIBLE column or modify an existing column to be INVISIBLE.

memoptimize_read_clause

Use this clause to improve the performance high frequency data query operations. The MEMOPTIMIZE_POOL_SIZE initialization parameter controls the size of the memoptimize pool. Note that the feature uses additional memory from the SGA.

- You must specify this clause as a top-level attribute of the table, it cannot be specified at the partition or subpartition level.
- You must explicitly enable the table for MEMOPTIMIZE FOR READ before you can read data from the table.
- You must explicitly disable the table for NO MEMOPTIMIZE FOR READ when you no longer need it.

memoptimize_write_clause

Use this clause to enable fast ingest. Fast ingest optimizes the processing of high frequency single row data inserts from Internet of Things (IoT) applications by using a large buffering pool to store the inserts before writing them to disk.

Restrictions

Blockchain and immutable tables do not support the *memoptimize_write_clause*.

alter_table_properties

Use the *alter_table_clauses* to modify a database table.

physical_attributes_clause

The *physical_attributes_clause* lets you change the value of the PCTFREE, PCTUSED, and INITRANS parameters and storage characteristics. Refer to *physical_attributes_clause* and storage_clause for a full description of these parameters and characteristics.

Restrictions on Altering Table Physical Attributes

Altering physical attributes is subject to the following restrictions:

- You cannot specify the `PCTUSED` parameter for the index segment of an index-organized table.
- If you attempt to alter the storage attributes of tables in locally managed tablespaces, then Oracle Database raises an error. However, if some segments of a partitioned table reside in a locally managed tablespace and other segments reside in a dictionary-managed tablespace, then the database alters the storage attributes of the segments in the dictionary-managed tablespace but does not alter the attributes of the segments in the locally managed tablespace, and does not raise an error.
- For segments with automatic segment-space management, the database ignores attempts to change the `PCTUSED` setting. If you alter the `PCTFREE` setting, then you must subsequently run the `DBMS_REPAIR.SEGMENT_FIX_STATUS` procedure to implement the new setting on blocks already allocated to the segment.

Cautions on Altering Tables Physical Attributes

The values you specify in this clause affect the table as follows:

- For a nonpartitioned table, the values you specify override any values specified for the table at create time.
- For a range-, list-, or hash-partitioned table, the values you specify are the default values for the table and the actual values for every existing partition, overriding any values already set for the partitions. To change default table attributes without overriding existing partition values, use the *`modify_table_default_attrs`* clause.
- For a composite-partitioned table, the values you specify are the default values for the table and all partitions of the table and the actual values for all subpartitions of the table, overriding any values already set for the subpartitions. To change default partition attributes without overriding existing subpartition values, use the *`modify_table_default_attrs`* clause with the `FOR PARTITION` clause.

logging_clause

Use the *`logging_clause`* to change the logging attribute of the table. The *`logging_clause`* specifies whether subsequent `ALTER TABLE ... MOVE` and `ALTER TABLE ... SPLIT` operations will be logged or not logged.

When used with the *`modify_table_default_attrs`* clause, this clause affects the logging attribute of a partitioned table.

> **See Also:**
>
> - *logging_clause* for a full description of this clause
> - *Oracle Database VLDB and Partitioning Guide* for more information about the *`logging_clause`* and parallel DML

table_compression

The *`table_compression`* clause is valid only for heap-organized tables. Use this clause to instruct Oracle Database whether to compress data segments to reduce disk and memory use. Refer to the `CREATE TABLE` *table_compression* for the full semantics of this clause and for information on creating objects with table compression.

> **Note:**
>
> The first time a table is altered in such a way that compressed data will be added, all bitmap indexes and bitmap index partitions on that table must be marked `UNUSABLE`.

inmemory_table_clause

Use this clause to enable or disable a table or table column for the In-Memory Column Store (IM column store), or to change the In-Memory attributes for a table or table column.

- Specify `INMEMORY` to enable a table for the IM column store, or to change the *`inmemory_attributes`* for a table that is already enabled for the IM column store.
- Specify `NO INMEMORY` to disable a table for the IM column store.
- Specify the *`inmemory_column_clause`* to enable or disable a table column for the IM column store, or to change the *`inmemory_memcompress`* setting for a table column. If you specify this clause when the table or partition is disabled for the IM column store, then the column settings will take effect when the table or partition is subsequently enabled for the IM column store. Regardless of whether the table or partition is enabled or disabled for the IM column store, when you specify `NO INMEMORY` for a column, any previously specified *`inmemory_memcompress`* setting for the column is lost. Refer to the *inmemory_column_clause* of `CREATE TABLE` for the full semantics of this clause.

This *`inmemory_table_clause`* has the same semantics as the *inmemory_table_clause* of `CREATE TABLE`, with the following additions:

- When you specify the *`inmemory_memcompress`* clause to change the data compression method for a table that is already enabled for the IM column store, any columns that were previously assigned a specific data compression method will retain that data compression method. Refer to the *inmemory_memcompress* clause of `CREATE TABLE` for more information on this clause.
- When you specify the *`inmemory_distribute`* clause, if you omit one subclause, then its setting remains unchanged. That is, if you specify only the `AUTO` or `BY` clause, then the `FOR SERVICE` setting for the table remains unchanged, and if you specify only the `FOR SERVICE` clause, then the `AUTO` or `BY` setting for the table remains unchanged. If you omit both subclauses and specify only the `DISTRIBUTE` keyword, then the table is assigned the `DISTRIBUTE AUTO` setting and its `FOR SERVICE` setting remains unchanged. Refer to the *inmemory_distribute* clause of `CREATE TABLE` for more information on this clause.
- When you specify `NO INMEMORY` to disable a partitioned or nonpartitioned table for the IM column store, any column-level In-Memory settings are lost. If you subsequently enable the table for the IM column store, then all columns will use the In-Memory settings for the table, unless you specify otherwise when enabling the table.
- When you specify `NO INMEMORY` to disable a partition for the IM column store, the column-level In-Memory settings are retained, even if all partitions in the table are disabled. If you subsequently enable the table or a partition for the IM column store, then the column-level In-Memory settings will go into effect, unless you specify otherwise when enabling the table or partition.
- If a table is currently populated in the IM column store and you change any *`inmemory_attribute`* of the table other than `PRIORITY`, then the database evicts the table from the IM column store. The repopulation behavior depends on the `PRIORITY` setting.

inmemory_clause

Use this clause to enable or disable a table partition for the IM column store, or to change the In-Memory parameters for a table partition. This clause has the same semantics in `CREATE TABLE` and `ALTER TABLE`. Refer to the *inmemory_clause* in the documentation on `CREATE TABLE` for the full semantics of this clause.

You can specify `INMEMORY` on non-partitioned tables using the `ORACLE_HIVE`, `ORACLE_HDFS`, and `ORACLE_BIGDATA` driver types.

For more details on the In-Memory column architecture see Oracle Database In-Memory Guide

Restriction

If a segment on disk is 64 KB or less, then it is not populated in the IM column store. Therefore, some small database objects that were enabled for the IM column store might not be populated.

ilm_clause

Use this clause to add, delete, enable, or disable Automatic Data Optimization policies for the table.

ADD POLICY

Specify this clause to add a policy for the table.

Use *`ilm_policy_clause`* to specify the policy. Refer to the *ilm_policy_clause* for the full semantics of this clause

Oracle Database assigns a name to the policy of the form `Pn` where *`n`* is an integer value

{ DELETE | ENABLE | DISABLE } POLICY

Specify these clauses to delete a policy for the table, enable a policy for the table, or disable a policy for the table, respectively.

For *`ilm_policy_name`*, specify the name of the policy. You can view policy names by querying the `POLICY_NAME` column of the `DBA_ILMPOLICIES` view.

{ DELETE_ALL, ENABLE_ALL, DISABLE_ALL }

Specify these clauses to delete all policies for the table, enable all policies for the table, or disable all policies for the table, respectively.

> **See Also:**
>
> *Oracle Database VLDB and Partitioning Guide* for more information on managing policies for Automatic Data Optimization

ilm_policy_clause

This clause lets you specify an Automatic Data Optimization policy. You can use the *`ilm_compression_policy`* clause to specify a compression policy, the *`ilm_tiering_policy`* clause to specify a storage tiering policy, or the *`ilm_inmemory_policy`* clause to specify an In-Memory Column Store policy.

ilm_compression_policy

Use this clause to specify a compression policy. This type of policy instructs the database to compress data when a specified condition is met. Use the `SEGMENT`, `GROUP`, or `ROW` clause to specify a segment-level, group-level, or row-level compression policy.

table_compression

Use the *`table_compression`* clause to specify the compression type. This clause applies to segment-level and group-level compression policies.

You must specify a compression type that is higher than the current compression type. The order of compression types from lowest to highest is:

```
NOCOMPRESS
ROW STORE COMPRESS BASIC
ROW STORE COMPRESS ADVANCED
COLUMN STORE COMPRESS FOR QUERY LOW
COLUMN STORE COMPRESS FOR QUERY HIGH
COLUMN STORE COMPRESS FOR ARCHIVE LOW
COLUMN STORE COMPRESS FOR ARCHIVE HIGH
```

Refer to *table_compression* for the full semantics of this clause.

SEGMENT

Specify `SEGMENT` to create a segment-level compression policy. This type of policy instructs the database to compress table segments when the condition specified in the `AFTER` clause is met or when the PL/SQL function specified in the `ON` clause returns `TRUE`.

Note that you cannot modify a segment using `ALTER TABLE`.

GROUP

Specify `GROUP` to create a group-level compression policy. This type of policy instructs the database to compress the table and its dependent objects, such as indexes and SecureFiles LOBs, when the condition specified in the `AFTER` clause is met or when the PL/SQL function specified in the `ON` clause returns `TRUE`.

ROW

Specify `ROW` to create a row-level compression policy. This type of policy instructs the database to compress database blocks in which all the rows have not been modified for a specified period of time. When creating a row-level policy, you must specify `ROW STORE COMPRESS ADVANCED` or `COLUMN STORE COMPRESS FOR QUERY` compression, and you must specify `AFTER` *`ilm_time_period`* `OF NO MODIFICATION`. Refer to *table_compression* for the full semantics of the `ROW STORE COMPRESS ADVANCED` and `COLUMN STORE COMPRESS FOR QUERY` clauses.

AFTER

Use this clause to describe the condition that must be met in order for the policy to take effect. The condition consists of a length of time, specified with the *`ilm_time_period`* clause, and one of the following condition types:

- `OF NO ACCESS`: The policy will take effect after table has not been accessed for the specified length of time.
- `OF NO MODIFICATION`: The policy will take effect after table has not been modified for the specified length of time.

- `OF CREATION`: The policy will take effect when the specified length of time has passed since table was created.

ilm_time_period

Specify a length of time in days, months, or years after which the condition must be met. For *integer*, specify a positive integer. The `DAY` and `DAYS` keywords can be used interchangeably and are provided for semantic clarity. This is also the case for the `MONTH` and `MONTHS` keywords, and the `YEAR` and `YEARS` keywords.

ON

Use this clause to specify a PL/SQL function that returns a boolean value. For *function_name*, specify the name of the function. The policy will take effect when the function returns `TRUE`.

> **Note:**
>
> The **`ON`** `function_name` clause is not supported for tablespaces.

ilm_tiering_policy

Use this clause to specify a storage tiering policy. This type of policy instructs the database to migrate data to a specified tablespace, either when a specified condition is met or when data usage reaches a specified limit. Use the `SEGMENT` or `GROUP` clause to specify a segment-level or group-level policy. You can migrate data to a read/write tablespace or a read-only tablespace.

TIER TO *tablespace*

Use this clause to migrate data to a read/write *tablespace*.

- If you specify the `ON` *function* clause, then data will be migrated when function returns `TRUE`. Refer to the ON clause for the full semantics of this clause.
- If you omit the `ON` *function* clause, then data will be migrated when data usage of the tablespace quota reaches the percentage defined by `TBS_PERCENT_USED`. The database will make a best effort to migrate enough data so that the amount of free space within the tablespace quota reaches the percentage defined by `TBS_PERCENT_FREE`. Refer to *Oracle Database PL/SQL Packages and Types Reference* for more information on `TBS_PERCENT_USED` and `TBS_PERCENT_FREE`, which are constants in the `DBMS_ILM_ADMIN` package.

TIER TO *tablespace* READ ONLY

Use this clause to migrate data to a read-only tablespace. When migrating data to the tablespace, the database temporarily places the tablespace in read/write mode, migrates the data, and then places the tablespace back in read-only mode.

- If you specify the `AFTER` clause, then data will be migrated when the specified condition is met. Refer to the AFTER clause for the full semantics of this clause
- If you specify the `ON` *function* clause, then data will be migrated when function returns `TRUE`. Refer to the ON clause for the full semantics of this clause.

SEGMENT | GROUP

Specify `SEGMENT` to create a segment-level storage tiering policy. This type of policy instructs the database to migrate table segments to *tablespace*. Specify `GROUP` to create a group-level storage tiering policy. This type of policy instructs the database to migrate the table and its

dependent objects, such as indexes and SecureFiles LOBs, to *tablespace*. The default is SEGMENT.

> **Note:**
>
> The **ON** function_name clause is not supported for tablespaces.

ilm_inmemory_policy

Use this clause to specify an In-Memory Column Store (IM column store) policy. This type of policy instructs the database to enable or disable the table for the IM column store, or to change the compression method for the table in the IM column store, when a specified condition is met.

SET INMEMORY

Use this clause to enable the table for the IM column store when the specified condition is met. You can optionally use the *inmemory_attributes* clause to specify how table data will be stored in the IM column store. Refer to *inmemory_attributes* for the full semantics of this clause.

MODIFY INMEMORY

Use this clause to change the compression method for table data stored in the IM column store when the specified condition is met. The table must be enabled for the IM column store.

You must specify a compression method that his higher than the current compression method. The order of compression methods from lowest to highest is:

```
NO INMEMORY
MEMCOMPRESS FOR DML
MEMCOMPRESS FOR QUERY LOW
MEMCOMPRESS FOR QUERY HIGH
MEMCOMPRESS FOR CAPACITY LOW
MEMCOMPRESS FOR CAPACITY HIGH
```

Refer to *inmemory_memcompress* for the full semantics of this clause.

NO INMEMORY

Use this clause to disable the table for the IM column store when the specified condition is met.

SEGMENT

The SEGMENT keyword is optional and is provided for semantic clarity. IM column store policies are always segment-level policies.

AFTER | ON

The AFTER and ON clauses enable you to specify the condition that must be met in order for the IM column store policy to take effect:

- If you specify the AFTER clause, then the policy will take effect when the specified condition is met. Refer to the AFTER clause for the full semantics of this clause
- If you specify the ON function clause, then the policy will take effect when function returns TRUE. Refer to the ON clause for the full semantics of this clause.

> **Note:**
>
> The `ON function_name` clause is not supported for tablespaces.

> **See Also:**
>
> *Oracle Database In-Memory Guide* for more information on using Automatic Data Optimization policies with the IM column store

supplemental_table_logging

Use the *supplemental_table_logging* clause to add or drop a redo log group or one or more supplementally logged columns in a redo log group.

- In the `ADD` clause, use *supplemental_log_grp_clause* to create named supplemental log group. Use the *supplemental_id_key_clause* to create a system-generated log group.
- On the `DROP` clause, use `GROUP` *log_group* syntax to drop a named supplemental log group and use the *supplemental_id_key_clause* to drop a system-generated log group.

The *supplemental_log_grp_clause* and the *supplemental_id_key_clause* have the same semantics in `CREATE TABLE` and `ALTER TABLE` statements. For full information on these clauses, refer to supplemental_log_grp_clause and supplemental_id_key_clause in the documentation on `CREATE TABLE`.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for information on supplemental redo log groups

allocate_extent_clause

Use the *allocate_extent_clause* to explicitly allocate a new extent for the table, the partition or subpartition, the overflow data segment, the LOB data segment, or the LOB index.

Restriction on Allocating Table Extents

You cannot allocate an extent for a temporary table or for a range- or composite-partitioned table.

> **See Also:**
>
> *allocate_extent_clause* for a full description of this clause and "Allocating Extents: Example"

deallocate_unused_clause

deallocate_unused_clause Use the *deallocate_unused_clause* to explicitly deallocate unused space at the end of the table, partition or subpartition, overflow data segment, LOB data segment, or LOB index and make the space available for other segments in the tablespace.

> **See Also:**
>
> *deallocate_unused_clause* for a full description of this clause and "Deallocating Unused Space: Example"

rename_lob_storage_clause

Specify this clause to rename a LOB data segment internally.

Specify the following arguments:

- *table_name*
- *column_name* can be of type BLOB or BLOB
- *old_segment_name* can query *all_lobs*, *all_lob_partition* or *all_lob_subpartition*
- PARTITION or SUBPARTITION for partitioned tables, NULL for non-partitioned tables
- *new_segment_name*. The rename ensures that the new segment name is unique within the database. A name conflict results in an error.

CACHE | NOCACHE

The CACHE and NOCACHE clauses have the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on these clauses, refer to "CACHE | NOCACHE | CACHE READS" in the documentation on CREATE TABLE. If you omit both of these clauses in an ALTER TABLE statement, then the existing value is unchanged.

result_cache_clause

The *result_cache_clause* clause has the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on this clause, refer to "*result_cache_clause*" in the documentation on CREATE TABLE. If you omit this clause in an ALTER TABLE statement, then the existing setting is unchanged.

Examples

```
ALTER TABLE employee RESULT_CACHE (MODE DEFAULT)
    ALTER TABLE employee RESULT_CACHE (STANDBY ENABLE)
    ALTER TABLE employee RESULT_CACHE (MODE DEFAULT, STANDBY ENABLE)
    ALTER TABLE employee RESULT_CACHE (STANDBY ENABLE, MODE FORCE)
```

upgrade_table_clause

The *upgrade_table_clause* is relevant for object tables and for relational tables with object columns. It lets you instruct Oracle Database to convert the metadata of the target table to conform with the latest version of each referenced type. If table is already valid, then the table metadata remains unchanged.

Restriction on Upgrading Object Tables and Columns

Within this clause, you cannot specify *object_type_col_properties* as a clause of *column_properties*.

INCLUDING DATA

Specify INCLUDING DATA if you want Oracle Database to convert the data in the table to the latest type version format. You can define the storage for any new column while upgrading the table by using the *column_properties* and the *LOB_partition_storage* . This is the default.

You can convert data in the table at the time you upgrade the type by specifying CASCADE INCLUDING TABLE DATA in the *dependent_handling_clause* of the ALTER TYPE statement. See *Oracle Database PL/SQL Language Reference* for information on this clause. For information on whether a table contains data based on an older type version, refer to the DATA_UPGRADED column of the USER_TAB_COLUMNS data dictionary view.

NOT INCLUDING DATA

Specify NOT INCLUDING DATA if you want Oracle Database to leave column data unchanged.

Restriction on NOT INCLUDING DATA

You cannot specify NOT INCLUDING DATA if the table contains columns in Oracle8 release 8.0.x image format. To determine whether the table contains such columns, refer to the V80_FMT_IMAGE column of the USER_TAB_COLUMNS data dictionary view.

> **See Also:**
>
> - *Oracle Database Reference* for information on the data dictionary views
> - ALTER TYPE for information on converting dependent table data when modifying a type upon which the table depends

records_per_block_clause

The *records_per_block_clause* lets you specify whether Oracle Database restricts the number of records that can be stored in a block. This clause ensures that any bitmap indexes subsequently created on the table will be as compressed as possible.

Restrictions on Records in a Block

The *record_per_block_clause* is subject to the following restrictions:

- You cannot specify either MINIMIZE or NOMINIMIZE if a bitmap index has already been defined on table. You must first drop the bitmap index.
- You cannot specify this clause for an index-organized table or a nested table.

MINIMIZE

Specify MINIMIZE to instruct Oracle Database to calculate the largest number of records in any block in the table and to limit future inserts so that no block can contain more than that number of records.

Oracle recommends that a representative set of data already exist in the table before you specify MINIMIZE. If you are using table compression (see *table_compression*), then a representative set of compressed data should already exist in the table.

Restriction on MINIMIZE

You cannot specify MINIMIZE for an empty table.

NOMINIMIZE

Specify NOMINIMIZE to disable the MINIMIZE feature. This is the default.

row_movement_clause

You cannot disable row movement in a reference-partitioned table unless row movement is also disabled in the parent table. Otherwise, this clause has the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on these clauses, refer to *row_movement_clause* in the documentation on CREATE TABLE.

logical_replication_clause

You can perform partial database replication for users such as Oracle GoldenGate, and reduce the supplemental logging overhead of uninteresting tables in interesting schema where supplemental logging is enabled. For full semantics see CREATE TABLE *logical_replication_clause*::=.

flashback_archive_clause

You must have the FLASHBACK ARCHIVE object privilege on the specified flashback archive to specify this clause. Use this clause to enable or disable historical tracking for the table.

- Specify FLASHBACK ARCHIVE to enable tracking for the table. You can specify *flashback_archive* to designate a particular flashback archive for this table. The flashback archive you specify must already exist.

  If you omit the archive name, then the database uses the default flashback archive designated for the system. If no default flashback archive has been designated for the system, then you must specify *flashback_archive*.

  You cannot specify FLASHBACK ARCHIVE to *change* the flashback archive for this table. Instead you must first issue an ALTER TABLE statement with the NO FLASHBACK ARCHIVE clause and then issue an ALTER TABLE statement with the FLASHBACK ARCHIVE clause.
- Specify NO FLASHBACK ARCHIVE to disable tracking for the table.

> **See Also:**
>
> The CREATE TABLE *flashback_archive_clause* for information on creating a table with tracking enabled and CREATE FLASHBACK ARCHIVE for information on creating default flashback archives

RENAME TO

Use the RENAME clause to rename *table* to *new_table_name*.

Using this clause invalidates any dependent materialized views. For more information on materialized views, see CREATE MATERIALIZED VIEW and *Oracle Database Data Warehousing Guide.*

If a domain index is defined on the table, then the database invokes the ODCIIndexAlter() method with the RENAME option. This operation establishes correspondence between the indextype metadata and the base table.

Restriction on Renaming Tables

You cannot rename a sharded table or a duplicated table.

shrink_clause

The shrink clause lets you manually shrink space in a table, index-organized table or its overflow segment, index, partition, subpartition, LOB segment, materialized view, or materialized view log. This clause is valid only for segments in tablespaces with automatic segment management. By default, Oracle Database compacts the segment, adjusts the high water mark, and releases the recuperated space immediately.

Compacting the segment requires row movement. Therefore, you must enable row movement for the object you want to shrink before specifying this clause. Further, if your application has any rowid-based triggers, you should disable them before issuing this clause.

With release 21c, you can use the *shrink_clause* on SecureFile LOB segments. There are two ways to invoke the *shrink_clause*:

1. This command targets a specific LOB column and all its partitions.

   ```
   ALTER TABLE <table_name> MODIFY LOB <lob_column> SHRINK SPACE
   ```

2. This command cascades the shrink operation for all the LOB columns and its partitions for the given table .

   ```
   ALTER TABLE <table_name> SHRINK SPACE CASCADE
   ```

Restrictions:

The *shrink_clause* is not supported on IOT partition tables.

> **Note:**
>
> Do not attempt to enable row movement for an index-organized table before specifying the *shrink_clause*. The ROWID of an index-organized table is its primary key, which never changes. Therefore, row movement is neither relevant nor valid for such tables.

COMPACT

If you specify COMPACT, then Oracle Database only defragments the segment space and compacts the table rows for subsequent release. The database does not readjust the high water mark and does not release the space immediately. You must issue another ALTER TABLE ... SHRINK SPACE statement later to complete the operation. This clause is useful if you want to accomplish the shrink operation in two shorter steps rather than one longer step.

For an index or index-organized table, specifying ALTER [INDEX | TABLE] ... SHRINK SPACE COMPACT is equivalent to specifying ALTER [INDEX | TABLE ... COALESCE. The *shrink_clause* can be cascaded (refer to the CASCADE clause, which follows) and compacts the segment more densely than does a coalesce operation, which can improve performance. However, if you do not want to release the unused space, then you can use the appropriate COALESCE clause.

CASCADE

If you specify CASCADE, then Oracle Database performs the same operations on all dependent objects of *table*, including secondary indexes on index-organized tables.

Restrictions on the *shrink_clause*

The *shrink_clause* is subject to the following restrictions:

- You cannot combine this clause with any other clauses in the same ALTER TABLE statement.

  You cannot specify this clause for a cluster, a clustered table, or any object with a LONG column.
- Segment shrink is not supported for tables with function-based indexes, domain indexes, or bitmap join indexes.
- This clause does not shrink mapping tables of index-organized tables, even if you specify CASCADE.
- You can specify this clause for a table with Advanced Row Compression enabled (ROW STORE COMPRESS ADVANCED). You cannot specify this clause for a table with any other type of table compression enabled.
- You cannot shrink a table that is the master table of an ON COMMIT materialized view. Rowid materialized views must be rebuilt after the shrink operation.

READ ONLY | READ WRITE

Specify READ ONLY to put the table in read-only mode. When the table is in READ ONLY mode, you cannot issue any DML statements that affect the table or any SELECT ... FOR UPDATE statements. You can issue DDL statements as long as they do not modify any table data. Operations on indexes associated with the table are allowed when the table is in READ ONLY mode. See *Oracle Database Administrator's Guide* for the complete list of operations that are allowed and disallowed on read-only tables.

Specify READ WRITE to return a read-only table to read/write mode.

REKEY *encryption_spec*

Use the REKEY clause to generate a new encryption key or to switch between different algorithms. This operation returns only after all encrypted columns in the table, including LOB columns, have been reencrypted.

DEFAULT COLLATION

This clause lets you change the default collation for the table. For *collation_name*, specify a valid named collation or pseudo-collation.

The new default collation for the table is assigned to columns of a character data type that are subsequently added to the table with an ALTER TABLE ADD statement or modified from a non-character data type with an ALTER TABLE MODIFY statement. The collations for existing columns in the table are not changed. Refer to the DEFAULT COLLATION clause of CREATE TABLE for the full semantics of this clause.

[NO] ROW ARCHIVAL

Specify this clause to enable or disable *table* for row archival.

- Specify ROW ARCHIVAL to enable *table* for row archival. A hidden column ORA_ARCHIVE_STATE is created in the table. If the table is already populated with data, then the value of ORA_ARCHIVE_STATE is set to 0 for each existing row in the table. You can subsequently use the UPDATE statement to set the value of ORA_ARCHIVE_STATE to 1 for rows you want to archive.

- Specify `NO ROW ARCHIVAL` to disable *`table`* for row archival. The hidden column `ORA_ARCHIVE_STATE` is dropped from the table.

Restrictions on [NO] ROW ARCHIVAL

The following restrictions apply to this clause:

- You cannot specify the `ROW ARCHIVAL` clause for a table that already contains a column named `ORA_ARCHIVE_STATE`.
- You cannot specify the `NO ROW ARCHIVAL` clause for tables owned by `SYS`.

> **See Also:**
>
> - The `CREATE TABLE` ROW ARCHIVAL clause for the full semantics of this clause
> - *Oracle Database VLDB and Partitioning Guide* for more information on In-Database Archiving

attribute_clustering_clause

Use the `ADD` *`attribute_clustering_clause`* to enable the table for attribute clustering. The *`attribute_clustering_clause`* has the same semantics for `ALTER TABLE` and `CREATE TABLE`. Refer to the *attribute_clustering_clause* in the documentation on `CREATE TABLE`.

MODIFY CLUSTERING

Use this clause to allow or disallow attribute clustering for the table during direct-path insert operations or data movement operations. The table must be enabled for attribute clustering. The *`clustering_when`* clause and the *`zonemap_clause`* have the same semantics for `ALTER TABLE` and `CREATE TABLE`. Refer to the clustering_when clause and the zonemap_clause in the documentation on `CREATE TABLE`.

DROP CLUSTERING

Use this clause to disable the table for attribute clustering.

If a zone map on the table was created using the `WITH MATERIALIZED ZONEMAP` clause of `CREATE TABLE` or `ALTER TABLE`, then the zone map will be dropped. If a zone map on the table was created using the `CREATE MATERIALIZED ZONEMAP` statement, then the zone map will not be dropped.

FOR STAGING

You can change the staging property of an exisiting table with `ALTER TABLE t FOR STAGING`. The staging table `t` now has all the characteristics of a staging table created with `CREATE TABLE t FOR STAGING`.

Refer to `CREATE TABLE` clause for the full semantics of staging tables: FOR STAGING

ALTER TABLE t NOT FOR STAGING

You can change a staging table with `ALTER TABLE t NOT FOR STAGING`. This means:

- You can enable compression explicitly on the table, its partitions, and future data loads.
- You can gather statistics on the table explictly or by using an statistics gathering application.

- When you drop the table, it can be put in the recyclebin.

alter_iot_clauses

index_org_table_clause

This clause lets you alter some of the characteristics of an existing index-organized table. Index-organized tables keep data sorted on the primary key and are therefore best suited for primary-key-based access and manipulation. See *index_org_table_clause* in the context of `CREATE TABLE`.

> **See Also:**
>
> "Modifying Index-Organized Tables: Examples"

prefix_compression

Use the *prefix_compression* clause to enable prefix compression for the table. Specify `COMPRESS` to instruct Oracle Database to combine the primary key index blocks of the index-organized table where possible to free blocks for reuse. You can specify this clause with the *parallel_clause*. Specify `NOCOMPRESS` to disable prefix compression for the table.

iot_advanced_compression

Specify *iot_advanced_compression* to compress the indexes of index organized tables (IOTs) and table partitions in order to reduce the storage footprint of IOTs.

You can enable advanced low index compression for all IOTs on specific partitions of a table, and leave other partitions uncompressed.

PCTTHRESHOLD *integer*

Refer to "PCTTHRESHOLD *integer*" in the documentation on `CREATE TABLE`.

INCLUDING *column_name*

Refer to "INCLUDING column_name" in the documentation on `CREATE TABLE`.

overflow_attributes

The *overflow_attributes* let you specify the overflow data segment physical storage and logging attributes to be modified for the index-organized table. Parameter values specified in this clause apply only to the overflow data segment.

> **See Also:**
>
> CREATE TABLE

add_overflow_clause

The *add_overflow_clause* lets you add an overflow data segment to the specified index-organized table. You can also use this clause to explicitly allocate an extent to or deallocate unused space from an existing overflow segment.

Use the `STORE IN` *`tablespace`* clause to specify tablespace storage for the entire overflow segment. Use the `PARTITION` clause to specify tablespace storage for the segment by partition.

For a partitioned index-organized table:

- If you do not specify `PARTITION`, then Oracle Database automatically allocates an overflow segment for each partition. The physical attributes of these segments are inherited from the table level.
- If you want to specify separate physical attributes for one or more partitions, then you must specify such attributes for *every* partition in the table. You need not specify the name of the partitions, but you must specify their attributes in the order in which they were created.

You can find the order of the partitions by querying the `PARTITION_NAME` and `PARTITION_POSITION` columns of the `USER_IND_PARTITIONS` view.

If you do not specify `TABLESPACE` for a particular partition, then the database uses the tablespace specified for the table. If you do not specify `TABLESPACE` at the table level, then the database uses the tablespace of the partition primary key index segment.

Restrictions on Overflow Attributes

Within the *`segment_attributes_clause`*:

- You cannot specify the `OPTIMAL` parameter of the *`physical_attributes_clause`*.
- You cannot specify tablespace storage for the overflow segment using this clause. For a nonpartitioned table, you can use `ALTER TABLE ... MOVE ... OVERFLOW` to move the segment to a different tablespace. For a partitioned table, use `ALTER TABLE ... MODIFY DEFAULT ATTRIBUTES ... OVERFLOW` to change the default tablespace of the overflow segment.

Additional restrictions apply if *`table`* is in a locally managed tablespace, because in such tablespaces several segment attributes are managed automatically by the database.

> **See Also:**
>
> *allocate_extent_clause* and *deallocate_unused_clause* for full descriptions of these clauses of the *`add_overflow_clause`*

alter_overflow_clause

The *`alter_overflow_clause`* lets you change the definition of the overflow segment of an existing index-organized table.

The restrictions that apply to the *`add_overflow_clause`* also apply to the *`alter_overflow_clause`*.

> **Note:**
>
> When you add a column to an index-organized table, Oracle Database evaluates the maximum size of each column to estimate the largest possible row. If an overflow segment is needed but you have not specified `OVERFLOW`, then the database raises an error and does not execute the `ALTER TABLE` statement. This checking function guarantees that subsequent DML operations on the index-organized table will not fail because an overflow segment is lacking.

alter_mapping_table_clauses

The *alter_mapping_table_clauses* is valid only if *table* is index organized and has a mapping table.

allocate_extent_clause

Use the *allocate_extent_clause* to allocate a new extent at the end of the mapping table for the index-organized table. Refer to *allocate_extent_clause* for a full description of this clause.

deallocate_unused_clause

Specify the *deallocate_unused_clause* to deallocate unused space at the end of the mapping table of the index-organized table. Refer to *deallocate_unused_clause* for a full description of this clause.

Oracle Database automatically maintains all other attributes of the mapping table or its partitions.

COALESCE Clause

Specify `COALESCE` to instruct Oracle Database to merge the contents of index blocks of the index the database uses to maintain the index-organized table where possible to free blocks for reuse. Refer to the *shrink_clause* for information on the relationship between these two clauses.

alter_XMLSchema_clause

This clause is valid as part of *alter_table_properties* only if you are modifying an `XMLType` table with `BINARY XML` storage. Refer to XMLSchema_spec in the documentation on `CREATE TABLE` for more information on the `ALLOW` and `DISALLOW` clauses.

column_clauses

Use these clauses to add, drop, or otherwise modify a column.

add_column_clause

The *add_column_clause* lets you add a column to a table.

> **See Also:**
>
> CREATE TABLE for a description of the keywords and parameters of this clause and "Adding a Table Column: Example"

Use `ALTER TABLE ADD` to associate columns to a domain:

```
ALTER TABLE  [owner.]name ADD (<column_list_def_clause> [, DOMAIN
[domain_owner.]domain_name (<column_name_list>)]+)
```

column_definition

Unless otherwise noted in this section, the elements of *column_definition* have the same behavior when adding a column to an existing table as they do when creating a new table. Refer to the*column_definition* clause of `CREATE TABLE` for information.

Restriction on *column_definition*

The `SORT` parameter is valid only when creating a new table. You cannot specify `SORT` in the column_definition of an `ALTER TABLE ... ADD` statement.

When you add a column, the initial value of each row for the new column is null, unless you specify the `DEFAULT` clause.

You can add an overflow data segment to each partition of a partitioned index-organized table.

You can add LOB columns to nonpartitioned and partitioned tables. You can specify LOB storage at the table and at the partition or subpartition level.

If you previously created a view with a query that used the `SELECT *` syntax to select all columns from table, and you now add a column to *table*, then the database does not automatically add the new column to the view. To add the new column to the view, re-create the view using the `CREATE VIEW` statement with the `OR REPLACE` clause. Refer to CREATE VIEW for more information.

Restrictions on Adding Columns

The addition of columns is subject to the following restrictions:

- You cannot add a LOB column or an `INVISIBLE` column to a cluster table.
- If you add a LOB column to a hash-partitioned table, then the only attribute you can specify for the new partition is `TABLESPACE`.
- You cannot add a column with a `NOT NULL` constraint if *table* has any rows unless you also specify the `DEFAULT` clause.
- If you specify this clause for an index-organized table, then you cannot specify any other clauses in the same statement.
- You cannot add a column to a duplicated table.

DEFAULT

Use the `DEFAULT` clause to specify a default for a new column or a new default for an existing column. Oracle Database assigns this value to the column if a subsequent `INSERT` statement omits a value for the column.

The data type of the expression must match the data type specified for the column. The column must also be large enough to hold this expression.

The `DEFAULT` expression can include any SQL function as long as the function does not return a literal argument, a column reference, or a nested function invocation.

The `DEFAULT` expression can include the sequence pseudocolumns `CURRVAL` and `NEXTVAL`, as long as the sequence exists and you have the privileges necessary to access it. Users who perform subsequent inserts that use the `DEFAULT` expression must have the `INSERT` privilege on

the table and the SELECT privilege on the sequence. If the sequence is later dropped, then subsequent insert statements where the DEFAULT expression is used will result in an error. If you are adding a new column to a table, then the order in which NEXTVAL is assigned to each existing row is nondeterministic. If you do not fully qualify the sequence by specifying the sequence owner, for example, SCOTT.SEQ1, then Oracle Database will default the sequence owner to be the user who issues the ALTER TABLE statement. For example, if user MARY adds a column to SCOTT.TABLE and refers to a sequence that is not fully qualified, such as SEQ2, then the column will use sequence MARY.SEQ2. Synonyms on sequences undergo a full name resolution and are stored as the fully qualified sequence in the data dictionary; this is true for public and private synonyms. For example, if user BETH adds a column referring to public or private synonym SYN1 and the synonym refers to PETER.SEQ7, then the column will store PETER.SEQ7 as the default.

If you specify the DEFAULT clause for a column, then the default value is stored as metadata but the column itself is not populated with data. However, subsequent queries that specify the new column are rewritten so that the default value is returned in the result set. This optimized behavior is subject to the following restrictions:

- It cannot be index-organized, temporary, or part of a cluster. It also cannot be a queue table, an object table, or the container table of a materialized view.
- If the table has a Virtual Private Database (VPD) policy on it, then the optimized behavior will not take place unless the user who issues the ALTER TABLE ... ADD statement has the EXEMPT ACCESS POLICY system privilege.
- The column being added cannot be encrypted, and cannot be an object column, nested table column, or a LOB column.
- The DEFAULT expression cannot include the sequence pseudocolumns CURRVAL or NEXTVAL.

If the optimized behavior cannot take place due to the preceding restrictions, then Oracle Database updates each row in the newly created column with the default value. In this case, the database does not fire any UPDATE triggers that are defined on the table.

Restrictions on Default Column Values

Default column values are subject to the following restrictions:

- A DEFAULT expression cannot contain references to PL/SQL functions or to other columns, the pseudocolumns LEVEL, PRIOR, and ROWNUM, or date constants that are not fully specified.
- The expression can be of any form except a scalar subquery expression.

ON NULL

If you specify the ON NULL clause, then Oracle Database assigns the DEFAULT column value when a subsequent INSERT or optionally an UPDATE statement attempts to assign a value that evaluates to NULL.

When you specify ON NULL, the NOT NULL constraint and NOT DEFERRABLE constraint state are implicitly specified. If you specify an inline constraint that conflicts with NOT NULL and NOT DEFERRABLE, then an error is raised.

Refer to CREATE TABLE ON NULL for the full semantics of DEFAULT ON NULL.

> **See Also:**
>
> "Specifying a Default Column Value: Examples"

identity_clause

The *identity_clause* has the same semantics when you add an identity column that it has when you create an identity column. Refer to CREATE TABLE *identity_clause* for more information.

When you add a new identity column to a table, all existing rows are updated using the sequence generator. The order in which a value is assigned to each existing row is nondeterministic.

identity_options

Use the *identity_options* clause to configure the sequence generator. The *identity_options* clause has the same parameters as the CREATE SEQUENCE statement. Refer to CREATE SEQUENCE for a full description of these parameters and characteristics. The exception is START WITH LIMIT VALUE, which is specific to *identity_options* and can only be used with ALTER TABLE MODIFY. Refer to identity_options for more information.

inline_constraint

Use *inline_constraint* to add a constraint to the new column.

inline_ref_constraint

This clause lets you describe a new column of type REF. Refer to *constraint* for syntax and description of this type of constraint, including restrictions.

virtual_column_definition

The *virtual_column_definition* has the same semantics when you add a column that it has when you create a column.

> **See Also:**
>
> The CREATE TABLE *virtual_column_definition* and "Adding a Virtual Table Column: Example" for more information

Restriction on Adding a Virtual Column

You cannot add a virtual column when the SQL expression for the virtual column involves a column on which an Oracle Data Redaction policy is defined.

column_properties

The clauses of *column_properties* determine the storage characteristics of an object type, nested table, varray, or LOB column.

object_type_col_properties

This clause is valid only when you are adding a new object type column or attribute. To modify the properties of an existing object type column, use the *modify_column_clauses*. The semantics of this clause are the same as for CREATE TABLE unless otherwise noted.

Use the *object_type_col_properties* clause to specify storage characteristics for a new object column or attribute or an element of a collection column or attribute.

For complete information on this clause, refer to object_type_col_properties in the documentation on CREATE TABLE.

nested_table_col_properties

The *nested_table_col_properties* clause lets you specify separate storage characteristics for a nested table, which in turn lets you to define the nested table as an index-organized table. You must include this clause when creating a table with columns or column attributes whose type is a nested table. (Clauses within this clause that function the same way they function for parent object tables are not repeated here. See the CREATE TABLE clause *nested_table_col_properties* for more information about these clauses.)

- For *nested_item*, specify the name of a column (or a top-level attribute of the nested table object type) whose type is a nested table.

  If the nested table is a multilevel collection, and the inner nested table does not have a name, then specify COLUMN_VALUE in place of the *nested_item* name.

- For *storage_table*, specify the name of the table where the rows of *nested_item* reside. The storage table is created in the same schema and the same tablespace as the parent table.

Restrictions on Nested Table Column Properties

Nested table column properties are subject to the following restrictions:

- You cannot specify the *parallel_clause*.
- You cannot specify CLUSTER as part of the *physical_properties* clause.

> **See Also:**
>
> "Nested Tables: Examples"

varray_col_properties

The *varray_col_properties* clause lets you specify separate storage characteristics for the LOB in which a varray will be stored. If you specify this clause, then Oracle Database will always store the varray in a LOB, even if it is small enough to be stored inline. If *varray_item* is a multilevel collection, then the database stores all collection items nested within *varray_item* in the same LOB in which *varray_item* is stored.

Restriction on Varray Column Properties

You cannot specify TABLESPACE as part of *LOB_parameters* for a varray column. The LOB tablespace for a varray defaults to the tablespace of the containing table.

out_of_line_part_storage

This clause lets you specify storage attributes the newly added column for each partition or subpartition in a partitioned table. For any partition or subpartition you do not name in this clause, the storage attributes for the new column are the same as those specified in the *nested_table_col_properties* at the table level.

LOB_storage_clause

Use the *LOB_storage_clause* to specify the LOB storage characteristics for a newly added LOB column, LOB partition, or LOB subpartition, or when you are converting a LONG column into a LOB column. You cannot use this clause to modify an existing LOB. Instead, you must use the *modify_LOB_storage_clause*.

Unless otherwise noted in this section, all LOB parameters, in both the *LOB_storage_clause* and the *modify_LOB_storage_clause*, have the same semantics in an ALTER TABLE statement that they have in a CREATE TABLE statement. Refer to the CREATE TABLE *LOB_storage_clause* for complete information on this clause.

Restriction on LOB Parameters

The only parameter of *LOB_parameters* you can specify for a hash partition or hash subpartition is TABLESPACE.

CACHE READS Clause

When you add a new LOB column, you can specify the logging attribute with CACHE READS, as you can when defining a LOB column at create time. Refer to the CREATE TABLE clause CACHE READS for full information on this clause.

ENABLE | DISABLE STORAGE IN ROW

You cannot change STORAGE IN ROW once it is set. Therefore, you cannot specify this clause as part of the *modify_col_properties* clause. However, you can change this setting when adding a new column (*add_column_clause*) or when moving the table (*move_table_clause*). Refer to the CREATE TABLE clause ENABLE STORAGE IN ROW for complete information on this clause.

CHUNK *integer*

You cannot use the *modify_col_properties* clause to change the value of CHUNK after it has been set. If you require a different CHUNK value for a column after it has been created, use ALTER TABLE … MOVE. Refer to the CREATE TABLE clause CHUNK integer for more information.

RETENTION

For BasicFiles LOBs, if the database is in automatic undo mode, then you can specify RETENTION instead of PCTVERSION to instruct Oracle Database to retain old versions of this LOB. This clause overrides any prior setting of PCTVERSION. Refer to the CREATE TABLE clause LOB_retention_clause for a full description of this parameter.

FREEPOOLS *integer*

For BasicFiles LOBs, if the database is in automatic undo mode, then you can use this clause to specify the number of freelist groups for this LOB. This clause overrides any prior setting of FREELIST GROUPS. Refer to the CREATE TABLE clause FREEPOOLS integer for a full description of this parameter. The database ignores this parameter for SecureFiles LOBs.

LOB_partition_storage

You can specify only one list of *LOB_partition_storage* clauses in a single ALTER TABLE statement, and all *LOB_storage_clauses* and *varray_col_properties* clause must precede the list of *LOB_partition_storage* clauses. Refer to the CREATE TABLE clause LOB_partition_storage for full information on this clause, including restrictions.

XMLType_column_properties

Refer to the CREATE TABLE clause *XMLType_column_properties* for a full description of this clause.

> **See Also:**
>
> - *LOB_storage_clause* for information on the *LOB_segname* and *LOB_parameters* clauses
> - "XMLType Column Examples" for an example of XMLType columns in object-relational tables and "Using XML in SQL Statements " for an example of creating an XMLSchema
> - *Oracle XML DB Developer's Guide* for more information on XMLType columns and tables and on creating an XMLSchema

XMLType_storage

Refer to the CREATE TABLE clause *XMLType_storage*.

JSON_storage_clause

With 21c you can define a column of JSON data type using the *JSON_storage_clause*.

Example

```
ALTER TABLE t ADD (jcol JSON)
```

modify_column_clauses

Use the *modify_column_clauses* to modify the properties of an existing column, the visibility of an existing column, or the substitutability of an existing object type column.

> **See Also:**
>
> "Modifying Table Columns: Examples"

modify_col_properties

Use this clause to modify the properties of the column. Any of the optional parts of the column definition (data type, default value, or constraint) that you omit from this clause remain unchanged.

datatype

You can change the data type of any column if all rows of the column contain nulls. However, if you change the data type of a column in a materialized view container table, then Oracle Database invalidates the corresponding materialized view.

You can omit the data type only if the statement also designates the column as part of the foreign key of a referential integrity constraint. The database automatically assigns the column the same data type as the corresponding column of the referenced key of the referential integrity constraint.

You can always increase the size of a character or raw column or the precision of a numeric column, whether or not all the rows contain nulls. You can reduce the size of a data type of a column as long as the change does not require data to be modified. The database scans existing data and returns an error if data exists that exceeds the new length limit.

When you increase the size of a `VARCHAR2`, `NVARCHAR2`, or `RAW` column to exceed 4000 bytes, Oracle Database performs an in-place length extension and does not migrate the inline storage to external LOB storage. This enables uninterrupted migration of large tables, especially after migration, to leverage extended data types. However, the inline storage of the column will not be preserved during table reorganization operations, such as `CREATE TABLE ... AS SELECT`, export, import, or online redefinition. To migrate to the new out-of-line storage of extended data type columns, you must recreate the table using one of the aforementioned methods. The inline storage of the column will be preserved during table or partition movement operations, such as `ALTER TABLE MOVE [[SUB]PARTITION]`, and partition maintenance operations, such as `ALTER TABLE SPLIT [SUB]PARTITION`, `ALTER TABLE MERGE [SUB]PARTITIONS`, and `ALTER TABLE COALESCE [SUB]PARTITIONS`.

> **Note:**
>
> Oracle recommends against excessively increasing the size of a `VARCHAR2`, `NVARCHAR2`, or `RAW` column beyond 4000 bytes for the following reasons:
>
> - Row chaining may occur.
> - Data that is stored inline must be read in its entirety, whether a column is selected or not. Therefore, extended data type columns that are stored inline can have a negative impact on performance.

You can reduce the size of a data type of a column as long as the change does not require data to be modified. The database scans existing data and returns an error if data exists that exceeds the new length limit.

You can change a `DATE` column to a `TIMESTAMP` or `TIMESTAMP WITH LOCAL TIME ZONE` column, and you can change a `TIMESTAMP` or `TIMESTAMP WITH LOCAL TIME ZONE` column to a `DATE` column. The following rules apply:

- When you change a `TIMESTAMP` or `TIMESTAMP WITH LOCAL TIME ZONE` column to a `DATE` column, Oracle Database updates each column value that has nonzero fractional seconds by rounding the value to the nearest second. If, while updating such a value, Oracle Database encounters a minute field greater than or equal to 60 (which can occur in a boundary case when the daylight saving rule switches), then it updates the minute field by subtracting 60 from it.
- After you change a `TIMESTAMP WITH LOCAL TIME ZONE` column to a `DATE` column, the values in the column still represent the local time that they represented in the database time zone. However, the database time zone is no longer associated with the values. When queried in SQL*Plus, the values are no longer automatically adjusted to the session time zone. It is

now the responsibility of applications processing the column values to interpret them in a particular time zone.

If the table is empty, then you can increase or decrease the leading field or the fractional second value of a datetime or interval column. If the table is not empty, then you can only increase the leading field or fractional second of a datetime or interval column.

You can use the `TO_LOB` function to change a `LONG` column to a `CLOB` or `NCLOB` column, and a `LONG RAW` column to a `BLOB` column. However, you cannot use the `TO_LOB` function from within a PL/SQL package. Instead use the `TO_CLOB` (character) or `TO_BLOB` (raw) functions.

- The modified LOB column inherits all constraints and triggers that were defined on the original `LONG` column. If you want to change any constraints, then you must do so in a subsequent `ALTER TABLE` statement.
- If any domain indexes are defined on the `LONG` column, then you must drop them before modifying the column to a LOB.
- After the modification, you will have to rebuild all other indexes on all columns of the table.

You can use the `TO_CLOB` (character) function to convert `NCLOB` columns `CLOB` columns.

> **See Also:**
>
> - *Oracle Database SecureFiles and Large Objects Developer's Guide* for information on `LONG` to LOB migration
> - ALTER INDEX for information on dropping and rebuilding indexes

For `CHAR` and `VARCHAR2` columns, you can change the length semantics by specifying `CHAR` (to indicate character semantics for a column that was originally specified in bytes) or `BYTE` (to indicate byte semantics for a column that was originally specified in characters). To learn the length semantics of existing columns, query the `CHAR_USED` column of the `ALL_`, `USER_`, or `DBA_TAB_COLUMNS` data dictionary view.

> **See Also:**
>
> - *Oracle Database Globalization Support Guide* for information on byte and character semantics
> - *Oracle Database Reference* for information on the data dictionary views

You can specify a user-defined data type as non-persistable when creating or altering the data type. Instances of non-persistable types cannot persist on disk. See CREATE TYPE for more on user-defined data types declared as non-persistable types.

DOMAIN

Use this clause to associate *`domain_name`* with the column. The domain's data type must be compatible with the column's data type.

COLLATE

Use this clause to set or change the data-bound collation for a column. For *column_collation_name*, specify a valid named collation or pseudo-collation. Refer to the DEFAULT COLLATION clause of CREATE TABLE for more information on data-bound collations.

Restrictions on Changing Column Collation

The modification of the column collation is subject to the following restrictions:

- If the column belongs to an index key, then its collation can only be changed:
  - among collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, and USING_NLS_SORT_CS
  - between collations BINARY_CI and USING_NLS_SORT_CI
  - between collations BINARY_AI and USING_NLS_SORT_AI
- If the column belongs to a range- or list-partitioning key, is referenced by a bitmap join index, belongs to the primary key of an index-organized table, or to the key of a domain index, including an Oracle Text index, then its collation can only be changed among the collations BINARY, USING_NLS_COMP, USING_NLS_SORT, and USING_NLS_SORT_CS.
- If the column belongs to an attribute clustering key, then its collation can only be changed between the collations BINARY and USING_NLS_COMP.

> **See Also:**
>
> Modifying the Collation of a Column for Fine-Grained Case-Insensitivity: Example

identity_clause

Use *identity_clause* to modify the properties of an identity column. You cannot specify this clause on a column that is not an identity column. If you do not specify ALWAYS or BY DEFAULT, then the current generation type is retained. Refer to CREATE TABLE *identity_clause* for more information on ALWAYS and BY DEFAULT.

identity_options

Use the *identity_options* clause to configure the sequence generator. The *identity_options* clause has the same parameters as the CREATE SEQUENCE statement. Refer to CREATE SEQUENCE for a full description of these parameters and characteristics. The exceptions are:

- START WITH LIMIT VALUE, which is specific to *identity_options*, can only be used with ALTER TABLE MODIFY. If you specify START WITH LIMIT VALUE, then Oracle Database locks the table and finds the maximum identity column value in the table (for increasing sequences) or the minimum identity column value (for decreasing sequences) and assigns the value as the sequence generator's high water mark. The next value returned by the sequence generator will be the high water mark + INCREMENT BY *integer* for increasing sequences, or the high water mark - INCREMENT BY *integer* for decreasing sequences.
- If you change the value of START WITH, then the default values will be used for all other parameters in this clause unless you specify otherwise.

DROP IDENTITY

Use this clause to remove the identity property from a column, including the sequence generator and NOT NULL and NOT DEFERRABLE constraints. Identity column values in existing rows are not affected.

ENCRYPT *encryption_spec* | DECRYPT

Use this clause to decrypt an encrypted column, to encrypt an unencrypted column, or to change the integrity algorithm or the `SALT` option of an encrypted column.

When encrypting an existing column, if you specify *encryption_spec*, it must match the encryption specification of any other encrypted columns in the same table. Refer to the `CREATE TABLE` clause *encryption_spec* for additional information and restrictions on the *encryption_spec*.

If a materialized view log is defined on the table, then Oracle Database encrypts or decrypts in the materialized view log any columns you encrypt or decrypt in this clause.

Restrictions on ENCRYPT *encryption_spec* | DECRYPT

This clause is subject to the following restrictions:

- If the new or existing column is a LOB column, then it must be stored as a SecureFiles LOB, and you cannot specify the `SALT` option.
- You cannot encrypt or decrypt a column on which a fine-grained audit policy for the `UPDATE` statement is enabled. However, you can disable the fine-grained audit policy, encrypt or decrypt the column, and then enable the fine-grained audit policy.

> **See Also:**
>
> "Data Encryption: Examples"

inline_constraint

This clause lets you add a constraint to a column you are modifying. To change the state of existing constraints on existing columns, use the *constraint_clauses*.

LOB_storage_clause

The *LOB_storage_clause* is permitted within *modify_col_properties* only if you are converting a `LONG` column to a LOB column. In this case only, you can specify LOB storage for the column using the *LOB_storage_clause*. However, you can specify only the single column as a *LOB_item*. Default LOB storage attributes are used for any attributes you omit in the *LOB_storage_clause*.

alter_XMLSchema_clause

This clause is valid within *modify_col_properties* only for `XMLType` tables with `BINARY XML` storage. Refer to XMLSchema_spec in the documentation on `CREATE TABLE` for more information on the `ALLOW` and `DISALLOW` clauses.

Restrictions on Modifying Column Properties

The modification of column properties is subject to the following restrictions:

- You cannot change the data type of a LOB column.
- You cannot modify a column of a table if a domain index is defined on the column. You must first drop the domain index and then modify the column.
- You cannot modify the data type or length of a column that is part of the partitioning or subpartitioning key of a table or index.

- You can change a `CHAR` column to `VARCHAR2` (or `VARCHAR`) and a `VARCHAR2` (or `VARCHAR`) column to `CHAR` only if the `BLANK_TRIMMING` initialization parameter is set to `TRUE` and the column size stays the same or increases. If the `BLANK_TRIMMING` initialization parameter is set to `TRUE`, then you can also reduce the column size to any size greater than or equal to the maximum trimmed data value.
- You cannot change a `LONG` or `LONG RAW` column to a LOB if the table is part of a cluster. If you do change a `LONG` or `LONG RAW` column to a LOB, then the only other clauses you can specify in this `ALTER TABLE` statement are the `DEFAULT` clause and the *`LOB_storage_clause`*.
- You can specify the *`LOB_storage_clause`* as part of *`modify_col_properties`* only when you are changing a `LONG` or `LONG RAW` column to a LOB.
- You cannot specify a column of data type `ROWID` for an index-organized table, but you can specify a column of type `UROWID`.
- You cannot change the data type of a column to `REF`.
- You cannot modify the properties of a column in a duplicated table.

> **See Also:**
>
> ALTER MATERIALIZED VIEW for information on revalidating a materialized view

modify_virtcol_properties

This clause lets you modify a virtual column in the following ways:

- Specify the `COLLATE` clause to set or change the data-bound collation for a virtual column. For *`column_collation_name`*, specify a valid named collation or pseudo-collation. Refer to the DEFAULT COLLATION clause of `CREATE TABLE` for more information on data-bound collations.
- If the virtual column refers to an editioned PL/SQL function, then you can modify the evaluation edition or the unusable editions for a virtual column. The *`evaluation_edition_clause`* and the *`unusable_editions_clause`* have the same semantics when you modify a virtual column that they have when you create a virtual column. For complete information, refer to evaluation_edition_clause and unusable_editions_clause in the documentation on `CREATE TABLE`.

Restrictions on Modifying Virtual Columns

The following restrictions apply to modifying virtual columns:

- Specifying the `COLLATE` clause to set or change the data-bound collation for a virtual column is subject to the restrictions listed in Restrictions on Changing Column Collation.
- If an index is defined on a virtual column and you modify its evaluation edition or unusable editions, then the database will invalidate all indexes on the virtual column. If you attempt to modify any other properties of the virtual column, then an error occurs.

modify_col_visibility

Use this clause to change the visibility of *`column`*. For complete information, refer to "VISIBLE | INVISIBLE" in the documentation on `CREATE TABLE`.

Restriction on Modifying Column Visibility

You cannot change a `VISIBLE` column to `INVISIBLE` in a table owned by `SYS`.

modify_col_substitutable

Use this clause to set or change the substitutability of an existing object type column.

The `FORCE` keyword drops any hidden columns containing typeid information or data for subtype attributes. You must specify `FORCE` if the column or any attributes of its type are not `FINAL`.

Restrictions on Modifying Column Substitutability

The modification of column substitutability is subject to the following restrictions:

- You can specify this clause only once in any `ALTER TABLE` statement.
- You cannot modify the substitutability of a column in an object table if the substitutability of the table itself has been set.
- You cannot specify this clause if the column was created or added using the `IS OF TYPE` syntax, which limits the range of subtypes permitted in an object column or attribute to a particular subtype. Refer to substitutable_column_clause in the documentation on `CREATE TABLE` for information on the `IS OF TYPE` syntax.
- You cannot change a varray column to `NOT SUBSTITUTABLE`, even by specifying `FORCE`, if any of its attributes are nested object types that are not `FINAL`.

***modify_domain*::=**

Use this clause to add or remove a domain from the table.

ADD DOMAIN

Use this to add a domain to the listed columns. You must specify as many columns as the domain. The first column is associated with the first domain column, second column is associated with the second domain column, and so on.

Example: Create a Domain phone_number and Add a Column

```
CREATE DOMAIN phone_number as VARCHAR2(12)
  CONSTRAINT CHECK (phone_number not like '%[0-9]%')
  NOT NULL;
```

To add a new column to a table with domain, the `ALTER TABLE` statement can be used as follows:

```
ALTER TABLE customers ADD (cust_cell_phone_number Varchar2(12) DOMAIN phone_number);

ALTER TABLE customers ADD (cust_cell_phone_number Varchar2(12) DOMAIN phone_number
DEFAULT ON NULL '650-000-0000');
```

DROP DOMAIN

Use this clause to dissociate a domain from the listed columns. The number of columns in this statement must match the number of columns in the domain.

If the domain has a collation, this will be preserved.

PRESERVE CONSTRAINTS

By default, any constraints from the domain are removed from the column. Use this clause to copy the domain constraints to the column.

An error is raised in the following cases:

- If you alter a column to have a collation different than the collation of the column's domain.
- If you alter a domain to add or modify the domain's collation to a value different than the collation of any column marked of the given domain.

drop_column_clause

The *drop_column_clause* lets you free space in the database by dropping columns you no longer need or by marking them to be dropped at a future time when the demand on system resources is less.

- If you drop a nested table column, then its storage table is removed.
- If you drop a LOB column, then the LOB data and its corresponding LOB index segment are removed.
- If you drop a `BFILE` column, then only the locators stored in that column are removed, not the files referenced by the locators.
- If you drop or mark unused a column defined as an `INCLUDING` column, then the column stored immediately before this column will become the new `INCLUDING` column.

SET UNUSED Clause

Specify `SET UNUSED` to mark one or more columns as unused. For an internal heap-organized table, specifying this clause does not actually remove the target columns from each row in the table. It does not restore the disk space used by these columns. Therefore, the response time is faster than when you execute the `DROP` clause.

When you specify this clause for a column in an external table, the clause is transparently converted to an `ALTER TABLE ... DROP COLUMN` statement. The reason for this is that any operation on an external table is a metadata-only operation, so there is no difference in the performance of the two commands.

You can view all tables with columns marked `UNUSED` in the data dictionary views `USER_UNUSED_COL_TABS`, `DBA_UNUSED_COL_TABS`, and `ALL_UNUSED_COL_TABS`.

> **See Also:**
>
> *Oracle Database Reference* for information on the data dictionary views

Unused columns are treated as if they were dropped, even though their column data remains in the table rows. After a column has been marked `UNUSED`, you have no access to that column. A `SELECT *` query will not retrieve data from unused columns. In addition, the names and types of columns marked `UNUSED` will not be displayed during a `DESCRIBE`, and you can add to the table a new column with the same name as an unused column.

> **Note:**
>
> Until you actually drop these columns, they continue to count toward the maximum number of columns in a single table, i.e. 1000 if the `MAX_COLUMNS` initialization parameter is set to `STANDARD`, or 4096 columns if `MAX_COLUMNS` is set to `EXTENDED`. However, as with all DDL statements, you cannot roll back the results of this clause. You cannot issue `SET USED` counterpart to retrieve a column that you have `SET UNUSED`. Refer to CREATE TABLE for more information on the 1000-column limit.
>
> Also, if you mark a `LONG` column as `UNUSED`, then you cannot add another `LONG` column to the table until you actually drop the unused `LONG` column.

ONLINE

Specify `ONLINE` to indicate that DML operations on the table will be allowed while marking the column or columns `UNUSED`.

Restrictions on Marking Columns Unused

The following restrictions apply to the `SET UNUSED` clause:

- You cannot specify the `ONLINE` clause when marking a column with a `DEFERRABLE` constraint as `UNUSED`.
- Columns in tables owned by `SYS` cannot be marked as `UNUSED`.

DROP Clause

Specify `DROP` to remove the column descriptor and the data associated with the target column from each row in the table. If you explicitly drop a particular column, then all columns currently marked `UNUSED` in the target table are dropped at the same time.

When the column data is dropped:

- All indexes defined on any of the target columns are also dropped.
- All constraints that reference a target column are removed.
- If any statistics types are associated with the target columns, then Oracle Database disassociates the statistics from the column with the `FORCE` option and drops any statistics collected using the statistics type.

> **Note:**
>
> If the target column is a parent key of a nontarget column, or if a check constraint references both the target and nontarget columns, then Oracle Database returns an error and does not drop the column unless you have specified the `CASCADE CONSTRAINTS` clause. If you have specified that clause, then the database removes all constraints that reference any of the target columns.

> **See Also:**
>
> DISASSOCIATE STATISTICS for more information on disassociating statistics types

DROP UNUSED COLUMNS Clause

Specify `DROP UNUSED COLUMNS` to remove from the table all columns currently marked as unused. Use this statement when you want to reclaim the extra disk space from unused columns in the table. If the table contains no unused columns, then the statement returns with no errors.

column

Specify one or more columns to be set as unused or dropped. Use the `COLUMN` keyword only if you are specifying only one column. If you specify a column list, then it cannot contain duplicates.

CASCADE CONSTRAINTS

Specify `CASCADE CONSTRAINTS` if you want to drop all foreign key constraints that refer to the primary and unique keys defined on the dropped columns as well as all multicolumn constraints defined on the dropped columns. If any constraint is referenced by columns from other tables or remaining columns in the target table, then you must specify `CASCADE CONSTRAINTS`. Otherwise, the statement aborts and an error is returned.

INVALIDATE

The `INVALIDATE` keyword is optional. Oracle Database automatically invalidates all dependent objects, such as views, triggers, and stored program units. Object invalidation is a recursive process. Therefore, all directly dependent and indirectly dependent objects are invalidated. However, only local dependencies are invalidated, because the database manages remote dependencies differently from local dependencies.

An object invalidated by this statement is automatically revalidated when next referenced. You must then correct any errors that exist in that object before referencing it.

> **See Also:**
>
> *Oracle Database Concepts* for more information on dependencies

CHECKPOINT

Specify `CHECKPOINT` if you want Oracle Database to apply a checkpoint for the `DROP COLUMN` operation after processing *`integer`* rows; *`integer`* is optional and must be greater than zero. If *`integer`* is greater than the number of rows in the table, then the database applies a checkpoint after all the rows have been processed. If you do not specify *`integer`*, then the database sets the default of 512. Checkpointing cuts down the amount of undo logs accumulated during the `DROP COLUMN` operation to avoid running out of undo space. However, if this statement is interrupted after a checkpoint has been applied, then the table remains in an unusable state. While the table is unusable, the only operations allowed on it are `DROP TABLE`, `TRUNCATE TABLE`, and `ALTER TABLE DROP ... COLUMNS CONTINUE` (described in sections that follow).

You cannot use this clause with `SET UNUSED`, because that clause does not remove column data.

DROP COLUMNS CONTINUE Clause

Specify `DROP COLUMNS CONTINUE` to continue the drop column operation from the point at which it was interrupted. Submitting this statement while the table is in an invalid state results in an error.

Restrictions on Dropping Columns

Dropping columns is subject to the following restrictions:

- Each of the parts of this clause can be specified only once in the statement and cannot be mixed with any other `ALTER TABLE` clauses. For example, the following statements are not allowed:

```
ALTER TABLE t1 DROP COLUMN f1 DROP (f2);
ALTER TABLE t1 DROP COLUMN f1 SET UNUSED (f2);
ALTER TABLE t1 DROP (f1) ADD (f2 NUMBER);
ALTER TABLE t1 SET UNUSED (f3)
   ADD (CONSTRAINT ck1 CHECK (f2 > 0));
```

- You can drop an object type column only as an entity. To drop an attribute from an object type column, use the `ALTER TYPE ... DROP ATTRIBUTE` statement with the `CASCADE INCLUDING TABLE DATA` clause. Be aware that dropping an attribute affects all dependent objects. See *Oracle Database PL/SQL Language Reference* for more information.
- You can drop a column from an index-organized table only if it is not a primary key column. The primary key constraint of an index-organized table can never be dropped, so you cannot drop a primary key column even if you have specified `CASCADE CONSTRAINTS`.
- You can export tables with dropped or unused columns. However, you can import a table only if all the columns specified in the export files are present in the table (none of those columns has been dropped or marked unused). Otherwise, Oracle Database returns an error.
- You can set unused a column from a table that uses `COMPRESS BASIC`, but you cannot drop the column. However, all clauses of the *`drop_column_clause`* are valid for tables that use `ROW STORE COMPRESS ADVANCED`. See the semantics for *table_compression* for more information.
- You cannot drop a column on which a domain index has been built.
- You cannot drop a `SCOPE` table constraint or a `WITH ROWID` constraint on a `REF` column.
- You cannot use this clause to drop:
  - A pseudocolumn, cluster column, or partitioning column. You can drop nonpartitioning columns from a partitioned table if all the tablespaces where the partitions were created are online and in read/write mode.
  - A column from a nested table, an object table, a duplicated table, or a table owned by `SYS`.

> **See Also:**
>
> "Dropping a Column: Example"

add_period_clause

Use the *add_period_clause* to add a valid time dimension to *table*.

The *period_definition* clause of ALTER TABLE has the same semantics as in CREATE TABLE, with the following exceptions and additions:

- *valid_time_column* must not already exist in *table*.
- If you specify *start_time_column* and *end_time_column*, then these columns must already exist in *table* or you must specify the *add_column_clause* for each of these columns.
- If you specify *start_time_column* and *end_time_column* and these columns already exist in *table* and are populated with data, then for all rows where both columns have non-NULL values, the value of *start_time_column* must be earlier than the value of *end_time_column*.

> **See Also:**
>
> CREATE TABLE *period_definition* for the full semantics of this clause

drop_period_clause

Use the *drop_period_clause* to drop a valid time dimension from *table*.

For *valid_time_column*, specify the name of the valid time dimension you want to drop.

This clause has the following effects:

- The *valid_time_column* will be dropped from *table*.
- If the start time column and end time column were automatically created by Oracle Database when the valid time dimension was created, either with CREATE TABLE ... *period_definition* or ALTER TABLE ... *add_period_clause*, then they will be dropped. Otherwise, these columns will remain in *table* and revert to regular table columns.

> **See Also:**
>
> CREATE TABLE *period_definition* for more information on the *valid_time_column*, start time column, and end time column

rename_column_clause

Use the *rename_column_clause* to rename a column of *table*. The new column name must not be the same as any other column name in *table*.

When you rename a column, Oracle Database handles dependent objects as follows:

- Function-based indexes and check constraints that depend on the renamed column remain valid.
- Dependent views, triggers, functions, procedures, and packages are invalidated. Oracle Database attempts to revalidate them when they are next accessed, but you may need to alter these objects with the new column name if revalidation fails.

- If a domain index is defined on the column being renamed, then the database invokes the ODCIIndexAlter method with the `RENAME` option. This operation establishes correspondence between the indextype metadata and the base table

Restrictions on Renaming Columns

Renaming columns is subject to the following restrictions:

- You cannot combine this clause with any of the other *`column_clauses`* in the same statement.
- You cannot rename a column that is used to define a join index. Instead you must drop the index, rename the column, and re-create the index.
- You cannot rename a column in a duplicated table.

> **See Also:**
>
> "Renaming a Column: Example"

modify_collection_retrieval

Use the *`modify_collection_retrieval`* clause to change what Oracle Database returns when a collection item is retrieved from the database.

collection_item

Specify the name of a column-qualified attribute whose type is nested table or varray.

RETURN AS

Specify what Oracle Database should return as the result of a query:

- `LOCATOR` specifies that a unique locator for the nested table is returned.
- `VALUE` specifies that a copy of the nested table itself is returned.

> **See Also:**
>
> "Collection Retrieval: Example"

modify_LOB_storage_clause

The *`modify_LOB_storage_clause`* lets you change the physical attributes of *`LOB_item`*. You can specify only one *`LOB_item`* for each *`modify_LOB_storage_clause`*.

The sections that follow describe the semantics of parameters specific to modify_LOB_parameters. Unless otherwise documented in this section, the remaining LOB parameters have the same semantics when altering a table that they have when you are creating a table. Refer to the restrictions at the end of this section and to the `CREATE TABLE` clause *LOB_storage_parameters* for more information.

> **Note:**
>
> - You can modify LOB storage with an `ALTER TABLE` statement or with online redefinition by using the `DBMS_REDEFINITION` package. If you have not enabled LOB encryption, compression, or deduplication at create time, Oracle recommends that you use online redefinition to enable them after creation, as this process is more disk space efficient for changes to these three parameters. See *Oracle Database PL/SQL Packages and Types Reference* for more information on `DBMS_REDEFINITION`.
> - You cannot convert a LOB from one type of storage to the other. Instead you must migrate to SecureFiles or BasicFiles by using online redefinition or partition exchange.

PCTVERSION *integer*

Refer to the `CREATE TABLE` clause PCTVERSION integer for information on this clause.

LOB_retention_clause

If the database is in automatic undo mode, then you can specify `RETENTION` instead of `PCTVERSION` to instruct Oracle Database to retain old versions of this LOB. This clause overrides any prior setting of `PCTVERSION`.

FREEPOOLS *integer*

For BasicFiles LOBs, if the database is in automatic undo mode, then you can use this clause to specify the number of freelist groups for this LOB. This clause overrides any prior setting of `FREELIST GROUPS`. Refer to the `CREATE TABLE` clause FREEPOOLS integer for a full description of this parameter. The database ignores this parameter for SecureFiles LOBs.

REBUILD FREEPOOLS

This clause applies only to BasicFiles LOBs, not to SecureFiles LOBs. The `REBUILD FREEPOOLS` clause removes all the old versions of data from the LOB column. This clause is useful for removing all retained old version space in a LOB segment, freeing that space to be used immediately by new LOB data.

LOB_deduplicate_clause

This clause is valid only for SecureFiles LOBs. `KEEP_DUPLICATES` disables LOB deduplication. `DEDUPLICATE` enables LOB deduplication. All lobs in the segment are read, and any matching LOBs are deduplicated before returning.

LOB_compression_clause

This clause is valid only for SecureFiles LOBs. `COMPRESS` compresses all LOBs in the segment and then returns. `NOCOMPRESS` uncompresses all LOBs in the segment and then returns.

ENCRYPT | DECRYPT

LOB encryption has the same semantics as column encryption in general. See "ENCRYPT encryption_spec | DECRYPT" for more information.

CACHE, NOCACHE, CACHE READS

When you modify a LOB column from `CACHE` or `NOCACHE` to `CACHE READS`, or from `CACHE READS` to `CACHE` or `NOCACHE`, you can change the logging attribute. If you do not specify `LOGGING` or

NOLOGGING, then this attribute defaults to the current logging attribute of the LOB column. If you do not specify CACHE, NOCACHE, or CACHE READS, then Oracle Database retains the existing values of the LOB attributes.

Restrictions on Modifying LOB Storage

Modifying LOB storage is subject to the following restrictions:

- You cannot modify the value of the INITIAL parameter in the *storage_clause* when modifying the LOB storage attributes.
- You cannot specify both the *allocate_extent_clause* and the *deallocate_unused_clause* in the same statement.
- You cannot specify both the PCTVERSION and RETENTION parameters.
- You cannot specify the *shrink_clause* for SecureFiles LOBs.

> **See Also:**
>
> *LOB_storage_clause* (in CREATE TABLE) for information on setting LOB parameters and "LOB Columns: Examples"

alter_varray_col_properties

The *alter_varray_col_properties* clause lets you change the storage characteristics of an existing LOB in which a varray is stored.

Restriction on Altering Varray Column Properties

You cannot specify the TABLESPACE clause of *LOB_parameters* as part of this clause. The LOB tablespace for a varray defaults to the tablespace of the containing table.

REKEY *encryption_spec*

The REKEY clause causes the database to generate a new encryption key. All encrypted columns in the table are reencrypted using the new key and, if you specify the USING clause of the *encryption_spec*, a new encryption algorithm. You cannot combine this clause with any other clauses in this ALTER TABLE statement.

> **See Also:**
>
> *Transparent Data Encryption* for more information on transparent column encryption

constraint_clauses

Use the *constraint_clauses* to add a new constraint using out-of-line declaration, modify the state of an existing constraint, or drop a constraint. Refer to *constraint* for a description of all the keywords and parameters of out-of-line constraints and *constraint_state*.

Adding a Constraint

The ADD clause lets you add a new out-of-line constraint or out-of-line REF constraint to the table.

Restrictions on Adding a Constraint

Adding constraints is subject to the following restrictions:

- You cannot add a constraint to a duplicated table.
- You cannot add a foreign key constraint to a sharded table.

> **See Also:**
>
> "Disabling a CHECK Constraint: Example", "Specifying Object Identifiers: Example", and "REF Columns: Examples"

Modifying a Constraint

The `MODIFY CONSTRAINT` clause lets you change the state of an existing constraint.

The `CASCADE` keyword is valid only when you are disabling a unique or primary key constraint on which a foreign key constraint is defined. In this case, you must specify `CASCADE` so that the unique or primary key constraint and all of its dependent foreign key constraints are disabled.

Like the other constraint states you can set the precheck state of a constraint to `PRECHECK` and unset it with `NOPRECHECK`.

Restrictions on Modifying Constraints

Modifying constraints is subject to the following restrictions:

- You cannot change the state of a `NOT DEFERRABLE` constraint to `INITIALLY DEFERRED`.
- If you specify this clause for an index-organized table, then you cannot specify any other clauses in the same statement.
- You cannot change the `NOT NULL` constraint on a foreign key column of a reference-partitioned table, and you cannot change the state of a partitioning referential constraint of a reference-partitioned table.
- You cannot modify a constraint on a duplicated table.
- You can specify `precheck_state` only with `constraint_name`. Primary key and unique constraints are not supported.

> **See Also:**
>
> - "Adding and Modifying Precheck State Constraint: Example"
> - "Changing the State of a Constraint: Examples"
> - *Explicitly Declaring Column Check Constraints Precheckable or Not*

Renaming a Constraint

The `RENAME CONSTRAINT` clause lets you rename any existing constraint on *`table`*. The new constraint name cannot be the same as any existing constraint on any object in the same schema. All objects that are dependent on the constraint remain valid.

> **See Also:**
>
> "Renaming Constraints: Example"

drop_constraint_clause

The *drop_constraint_clause* lets you drop an integrity constraint from the database. Oracle Database stops enforcing the constraint and removes it from the data dictionary. You can specify only one constraint for each *drop_constraint_clause*, but you can specify multiple *drop_constraint_clause* in one statement.

PRIMARY KEY

Specify PRIMARY KEY to drop the primary key constraint of *table*.

UNIQUE

Specify UNIQUE to drop the unique constraint on the specified columns.

If you drop the primary key or unique constraint from a column on which a bitmap join index is defined, then Oracle Database invalidates the index. See CREATE INDEX for information on bitmap join indexes.

CONSTRAINT

Specify CONSTRAINT *constraint_name* to drop an integrity constraint other than a primary key or unique constraint.

CASCADE

Specify CASCADE if you want all other integrity constraints that depend on the dropped integrity constraint to be dropped as well.

KEEP INDEX | DROP INDEX

Specify KEEP INDEX or DROP INDEX to indicate whether Oracle Database should preserve or drop the index it has been using to enforce the PRIMARY KEY or UNIQUE constraint.

ONLINE

Specify ONLINE to indicate that DML operations on the table will be allowed while dropping the constraint.

Restrictions on Dropping Constraints

Dropping constraints is subject to the following restrictions:

- You cannot drop a primary key or unique key constraint that is part of a referential integrity constraint without also dropping the foreign key. To drop the referenced key and the foreign key together, use the CASCADE clause. If you omit CASCADE, then Oracle Database does not drop the primary key or unique constraint if any foreign key references it.
- You cannot drop a primary key constraint (even with the CASCADE clause) on a table that uses the primary key as its object identifier (OID).
- If you drop a referential integrity constraint on a REF column, then the REF column remains scoped to the referenced table.
- You cannot drop the scope of a REF column.

- You cannot drop the `NOT NULL` constraint on a foreign key column of a reference-partitioned table, and you cannot drop a partitioning referential constraint of a reference-partitioned table.
- You cannot drop the `NOT NULL` constraint on a column that is defined with a default column value using the `ON NULL` clause.
- You cannot specify the `ONLINE` clause when dropping a `DEFERRABLE` constraint.

> **See Also:**
>
> "Dropping Constraints: Examples"

alter_external_table

Use the *alter_external_table* clauses to change the characteristics of an external table. This clause has no affect on the external data itself. The syntax and semantics of the *parallel_clause*, *enable_disable_clause*, *external_table_data_props*, and `REJECT LIMIT` clause are the same as described for `CREATE TABLE`. See the *external_table_clause* (in `CREATE TABLE`).

PROJECT COLUMN Clause

This clause lets you determine how the access driver validates the rows of an external table in subsequent queries. The default is `PROJECT COLUMN ALL`, which means that the access driver processes all column values, regardless of which columns are selected, and validates only those rows with fully valid column entries. If any column value would raise an error, such as a data type conversion error, then the row is rejected even if that column was not referenced in the select list. If you specify `PROJECT COLUMN REFERENCED`, then the access driver processes only those columns in the select list.

The `ALL` setting guarantees consistent result sets. The `REFERENCED` setting can result in different numbers of rows returned, depending on the columns referenced in subsequent queries, but is faster than the `ALL` setting. If a subsequent query selects all columns of the external table, then the settings behave identically.

Restrictions on Altering External Tables

Altering external tables is subject to the following restrictions:

- You cannot modify an external table using any clause outside of this clause.
- You cannot add a `LONG`, varray, or object type column to an external table, nor can you change the data type of an external table column to any of these data types.
- You cannot modify the storage parameters of an external table.

alter_table_partitioning

The clauses in this section apply only to partitioned tables. You cannot combine partition operations with other partition operations or with operations on the base table in the same `ALTER TABLE` statement.

Notes on Changing Table Partitioning

The following notes apply when changing table partitioning:

- If you drop, exchange, truncate, move, modify, or split a partition on a table that is a master table for one or more materialized views, then existing bulk load information about the table will be deleted. Therefore, be sure to refresh all dependent materialized views before performing any of these operations.
- If a bitmap join index is defined on *table*, then any operation that alters a partition of *table* causes Oracle Database to mark the index UNUSABLE.
- The only *alter_table_partitioning* clauses you can specify for a reference-partitioned table are *modify_table_default_attrs*, *move_table_[sub]partition*, *truncate_partition_subpart*, and *exchange_partition_subpart*. None of these operations cascade to any child table of the reference-partitioned table. No other partition maintenance operations are valid on a reference-partitioned table, but you can specify the other partition maintenance operations on the parent table of a reference-partitioned table, and the operation will cascade to the child reference-partitioned table.
- When adding partitions and subpartitions, bear in mind that you can specify up to a total of 1024K-1 partitions and subpartitions for each table.
- When you add a table partition or subpartition and you omit the partition name, the database generates a name using the rules described in "Notes on Partitioning in General".
- When you move, add (hash only), coalesce, drop, split, merge, rename, or truncate a table partition or subpartition, the procedures, functions, packages, package bodies, views, type bodies, and triggers that reference the table remain valid. All other dependent objects are invalidated.
- Deferred segment creation is not supported for partition maintenance operations that create new segments on tables with LOB columns; segments will always be created for the involved (sub)partitions.
- For sharded tables, the only clauses you can specify for modifying table partitions and subpartitions are UNUSABLE LOCAL INDEXES and REBUILD UNUSABLE LOCAL INDEXES. You cannot perform any other modifications for individual partitions and subpartitions on a system sharded table.
- For user-defined sharded tables the following operations on partitions and subpartitions are supported:
  - add partition, add subpartition
  - drop partition, drop subpartition
  - split partition
  - modify partition to add or drop values to a list partition
- For sharded tables, the only supported partition maintenance operations are truncating partitions and subpartitions. You cannot perform any other partition maintenance operations on a sharded table.

For additional information on partition operations on tables with an associated CONTEXT domain index, refer to *Oracle Text Reference*.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to *Oracle Database VLDB and Partitioning Guide* for a discussion of these restrictions.

modify_table_default_attrs

The *modify_table_default_attrs* clause lets you specify new default values for the attributes of *table*. Only attributes named in the statement are affected. Partitions and LOB partitions

you create subsequently will inherit these values unless you override them explicitly when creating the partition or LOB partition. Existing partitions and LOB partitions are not affected by this clause.

Only attributes named in the statement are affected, and the default values specified are overridden by any attributes specified at the individual partition or LOB partition level.

- FOR *partition_extended_name* applies only to composite-partitioned tables. This clause specifies new default values for the attributes of the partition identified in *partition_extended_name*. Subpartitions and LOB subpartitions of that partition that you create subsequently will inherit these values unless you override them explicitly when creating the subpartition or LOB subpartition. Existing subpartitions are not affected by this clause.

  If you are modifying the default directory, you can save its location using DEFAULT DIRECTORY *directory*.

- PCTTHRESHOLD, *prefix_compression*, and the *alter_overflow_clause* are valid only for partitioned index-organized tables.
- You can specify the *prefix_compression* clause only if prefix compression is already specified at the table level. Further, you cannot specify an integer after the COMPRESS keyword. Prefix length can be specified only when you create the table.
- You cannot specify the PCTUSED parameter in *segment_attributes* for the index segment of an index-organized table.
- The *read_only_clause* lets you modify the default read-only or read/write mode for the table. The new default mode will be assigned to partitions or subpartitions that are subsequently added to the table, unless you override this behavior by specifying the mode for the new partition or subpartition. When you modify the default read-only or read/write mode of a table, you do not change the mode of the existing partitions and subpartitions in the table. Refer to the *read_only_clause* of CREATE TABLE for the full semantics of this clause.
- The *indexing_clause* lets you modify the default indexing property for the table. The new default indexing property will be assigned to partitions or subpartitions that are subsequently added to the table, unless you override this behavior by specifying the indexing property for the new partition or subpartition. When you modify the default indexing property of a table, you do not change the indexing property of the existing partitions and subpartitions in the table. Refer to the *indexing_clause* of CREATE TABLE for the full semantics of this clause.

alter_automatic_partitioning

This clause allows you to manage automatic list-partitioned tables, as follows:

- Use the SET PARTITIONING AUTOMATIC clause to convert a regular list-partitioned table to an automatic list-partitioned table.
- Use the SET PARTITIONING MANUAL clause to convert an automatic list-partitioned table to a regular list-partitioned table.
- You can specify the SET STORE IN clause only for automatic list-partitioned tables. It lets you specify one or more tablespaces into which the database will store data for any subsequent automatically created list partitions. This clause overrides any tablespaces that might have been set for the table by a previously issued SET STORE IN clause.

To determine whether an existing table is an automatic list-partitioned table, you can query the AUTOLIST column of the USER_, DBA_, ALL_PART_TABLES data dictionary views.

Restriction on *alter_automatic_partitioning*

You cannot convert a regular list-partitioned table that contains a `DEFAULT` partition to an automatic list-partitioned table.

> **See Also:**
>
> The AUTOMATIC clause in the documentation on `CREATE TABLE` for more information on automatic list-partitioned tables

alter_interval_partitioning

Use this clause:

- To convert an existing range-partitioned table to interval partitioning. The database automatically creates partitions of the specified numeric range or datetime interval as needed for data beyond the highest value allowed for the last range partition. If the table has reference-partitioned child tables, then the child tables are converted to interval reference-partitioned child tables.
- To change the interval of an existing interval-partitioned table. The database first converts existing interval partitions to range partitions and determines the high value of the defined range partitions. The database then automatically creates partitions of the specified numeric range or datetime interval as needed for data that is beyond that high value.
- To change the tablespace storage for an existing interval-partitioned table. If the table has interval reference-partitioned child tables, then the new tablespace storage is inherited by any child table that does not have its own table-level default tablespace.
- To change an interval-partitioned table back to a range-partitioned table. Use `SET INTERVAL ()` to disable interval partitioning. The database converts existing interval partitions to range partitions, using the higher boundaries of created interval partitions as upper boundaries for the range partitions to be created. If the table has interval reference-partitioned child tables, then the child tables are converted to ordinary reference-partitioned child tables.

For *`expr`*, specify a valid number or interval expression.

> **See Also:**
>
> The `CREATE TABLE` "INTERVAL Clause" and *Oracle Database VLDB and Partitioning Guide* for more information on interval partitioning

set_subpartition_template

Use the *`set_subpartition_template`* clause to create or replace existing default range, list, or hash subpartition definitions for each table partition. This clause is valid only for composite-partitioned tables. It replaces the existing subpartition template or creates a new template if you have not previously created one. Existing subpartitions are not affected, nor are existing local and global indexes. However, subsequent partitioning operations (such as add and merge operations) will use the new template.

You can drop an existing subpartition template by specifying `ALTER TABLE` *`table`* `SET SUBPARTITION TEMPLATE ()`.

The *set_subpartition_template* clause has the same semantics as the *subpartition_template* clause of CREATE TABLE. Refer to the *subpartition_template* clause of CREATE TABLE for more information.

modify_table_partition

The *modify_table_partition* clause lets you change the real physical attributes of a range, hash, list partition, or system partition. This clause optionally modifies the storage attributes of one or more LOB items for the partition. You can specify new values for physical attributes (with some restrictions, as noted in the sections that follow), logging, and storage parameters.

For all types of partitions, you can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "UNUSABLE LOCAL INDEXES Clauses".

For partitioned index-organized tables, you can also update the mapping table in conjunction with partition changes. See the *alter_mapping_table_clauses* .

read_only_clause

Use the *read_only_clause* to put a table partition in read-only or read/write mode. Refer to the *read_only_clause* of CREATE TABLE for the full semantics of this clause.

indexing_clause

Use the *indexing_clause* to modify the indexing property of a table partition. The indexing property determines whether the partition is included in partial indexes on the table. You can specify the *indexing_clause* in the *modify_range_partition*, *modify_hash_partition*, and *modify_list_partition* clauses.

Specify INDEXING ON to change the indexing property for a table partition to ON. This operation has no effect on full indexes on the table. It has the following effects on partial indexes on the table:

- Local partial indexes: The table partition is included in the index. The corresponding index partition is rebuilt and marked USABLE.
- Global partial indexes: The table partition is included in the index. Index entries for the table partition are added to the index as part of routine index maintenance.

Specify INDEXING OFF to change the indexing property for a table partition to OFF. This operation has no effect on full indexes on the table. It has the following effects on partial indexes on the table:

- Local partial indexes: The table partition is excluded from the index. The corresponding index partition is marked UNUSABLE.
- Global partial indexes: The table partition is excluded from the index. Index entries for the table partition are removed from the index. This is a metadata-only operation and the index entries will continue to be physically stored in the index. You can remove these orphaned index entries by specifying COALESCE CLEANUP in the ALTER INDEX statement or in the *modify_index_partition* clause.

Restriction on column of type object

You cannot partition a table that has an object type. The alter table modification to a partitioned state is only supported for non-partitioned heap tables with zero columns of type object.

Restriction on the *indexing_clause*

You can specify this clause only for partitions of a simple partitioned table. For composite-partitioned tables, you can specify the *indexing_clause* at the table subpartition level. Refer to *modify_table_subpartition* for more information.

Notes on Modifying Table Partitions

The following notes apply to operations on range, list, and hash table partitions:

- For all types of table partition, in the *partition_attributes* clause, the *shrink_clause* lets you compact an individual partition segment. Refer to *shrink_clause* for additional information on this clause.
- The syntax and semantics for modifying a system partition are the same as those for modifying a hash partition. Refer to *modify_hash_partition*.
- If *table* is composite partitioned, then:
  - If you specify the *allocate_extent_clause*, then Oracle Database allocates an extent for each subpartition of *partition*.
  - If you specify the *deallocate_unused_clause*, then Oracle Database deallocates unused storage from each subpartition of *partition*.
  - Any other attributes changed in this clause will be changed in subpartitions of *partition* as well, overriding existing values. To avoid changing the attributes of existing subpartitions, use the FOR PARTITION clause of *modify_table_default_attrs*.
- When you modify the *partition_attributes* of a table partition with equipartitioned nested tables, the changes do not apply to the nested table partitions corresponding to the table partition being modified. However, you can modify the storage table of the nested table partition directly with an ALTER TABLE statement.
- Unless otherwise documented, the remaining clauses of *partition_attributes* have the same behavior they have when you are creating a partitioned table. Refer to the CREATE TABLE *table_partitioning_clauses* for more information.

> **See Also:**
>
> "Modifying Table Partitions: Examples"

modify_range_partition

Use this clause to modify the characteristics of a range partition.

add_range_subpartition

This clause is valid only for range-range composite partitions. It lets you add one or more range subpartitions to *partition*.

Starting with Oracle Database 12*c* Release 2 (12.2), you can use this clause to add a subpartition to composite-partitioned external table. In this case, you can specify the optional *external_part_subpart_data_props* clause of the *range_subpartition_desc* clause. Refer to external_part_subpart_data_props for the full semantics of this clause.

Restriction on Adding Range Subpartitions

If *table* is an index-organized table, then you can add only one range subpartition at a time.

add_hash_subpartition

This clause is valid only for range-hash composite partitions. The *add_hash_subpartition* clause lets you add a hash subpartition to *partition*. Oracle Database populates the new subpartition with rows rehashed from the other subpartition(s) of *partition* as determined by the hash function. For optimal load balancing, the total number of subpartitions should be a power of 2.

In the *partitioning_storage_clause*, the only clause you can specify for subpartitions is the TABLESPACE clause. If you do not specify TABLESPACE, then the new subpartition will reside in the default tablespace of *partition*.

Oracle Database adds local index partitions corresponding to the selected partition.

Oracle Database marks UNUSABLE the local index partitions corresponding to the added partitions. The database invalidates any indexes on heap-organized tables. You can update these indexes during this operation using the *update_index_clauses*.

add_list_subpartition

This clause is valid only for range-list and list-list composite partitions. It lets you add one or more list subpartitions to *partition*, and only if you have not already created a DEFAULT subpartition.

- The *list_values_clause* is required in this operation, and the values you specify in the *list_values_clause* cannot exist in any other subpartition of *partition*. However, these values can duplicate values found in subpartitions of other partitions.
- In the *partitioning_storage_clause*, the only clauses you can specify for subpartitions are the TABLESPACE clause and table compression.
- Starting with Oracle Database 12*c* Release 2 (12.2), you can use this clause to add a subpartition to composite-partitioned external table. In this case, you can specify the optional *external_part_subpart_data_props* clause of the *list_subpartition_desc* clause. Refer to external_part_subpart_data_props for the full semantics of this clause.

For each added subpartition, Oracle Database also adds a subpartition with the same value list to all local index partitions of the table. The status of existing local and global index partitions of *table* are not affected.

Restrictions on Adding List Subpartitions

The following restrictions apply to adding list subpartitions:

- You cannot specify this clause if you have already created a DEFAULT subpartition for this partition. Instead you must split the DEFAULT partition using the *split_list_subpartition* clause.
- If *table* is an index-organized table, then you can add only one list subpartition at a time.

coalesce_table_subpartition

COALESCE SUBPARTITION applies only to hash subpartitions. Use the COALESCE SUBPARTITION clause if you want Oracle Database to select the last hash subpartition, distribute its contents into one or more remaining subpartitions (determined by the hash function), and then drop the last subpartition.

- Oracle Database drops local index partitions corresponding to the selected partition.

- Oracle Database marks `UNUSABLE` the local index partitions corresponding to one or more absorbing partitions. The database invalidates any global indexes on heap-organized tables. You can update these indexes during this operation using the *update_index_clauses*.

modify_hash_partition

When modifying a hash partition, in the *partition_attributes* clause, you can specify only the *allocate_extent_clause* and *deallocate_unused_clause*. All other attributes of the partition are inherited from the table-level defaults except `TABLESPACE`, which stays the same as it was at create time.

modify_list_partition

Clauses available to you when modifying a list partition have the same semantics as when you are modifying a range partition. When modifying a list partition, the following additional clauses are available:

ADD | DROP VALUES Clauses

These clauses are valid only when you are modifying composite partitions. Local and global indexes on the table are not affected by either of these clauses.

- Use the `ADD VALUES` clause to extend the *partition_key_value* list of *partition* to include additional values. The added partition values must comply with all rules and restrictions listed in the `CREATE TABLE` clause *list_partitions* .
- Use the `DROP VALUES` clause to reduce the *partition_key_value* list of *partition* by eliminating one or more *partition_key_value*. When you specify this clause, Oracle Database checks to ensure that no rows with this value exist. If such rows do exist, then Oracle Database returns an error.

> **Note:**
>
> `ADD VALUES` and `DROP VALUES` operations on a table with a `DEFAULT` list partition are enhanced if you have defined a local prefixed index on the table.

Restrictions on Adding and Dropping List Values

Adding and dropping list values are subject to the following restrictions:

- You cannot add values to or drop values from a `DEFAULT` list partition.
- If *table* contains a `DEFAULT` partition and you attempt to add values to a nondefault partition, then Oracle Database will check that the values being added do not already exist in the `DEFAULT` partition. If the values do exist in the `DEFAULT` partition, then Oracle Database returns an error.

modify_table_subpartition

This clause applies only to composite-partitioned tables. Its subclauses let you modify the characteristics of an individual range, list, or hash subpartition.

The *shrink_clause* lets you compact an individual subpartition segment. Refer to *shrink_clause* for additional information on this clause.

You can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "UNUSABLE LOCAL INDEXES Clauses".

Use the *read_only_clause* to put a table subpartition in read-only or read/write mode. Refer to the *read_only_clause* of CREATE TABLE for the full semantics of this clause.

Use the *indexing_clause* to modify the indexing property of a table subpartition. The indexing property determines whether the subpartition is included in partial indexes on the table. Modifying the indexing property of table subpartitions has the same effect on index subpartitions as modifying the indexing property of table partitions has on index partitions. Refer to the indexing_clause of *modify_table_partition* for details.

Restriction on Modifying Hash Subpartitions

The only *modify_LOB_parameters* you can specify for *subpartition* are the *allocate_extent_clause* and *deallocate_unused_clause*.

ADD | DROP VALUES Clauses

These clauses are valid only when you are modifying list subpartitions. Local and global indexes on the table are not affected by either of these clauses.

- Use the ADD VALUES clause to extend the *subpartition_key_value* list of *subpartition* to include additional values. The added partition values must comply with all rules and restrictions listed in the CREATE TABLE clause *list_partitions* .
- Use the DROP VALUES clause to reduce the *subpartition_key_value* list of *subpartition* by eliminating one or more *subpartition_key_value*. When you specify this clause, Oracle Database checks to ensure that no rows with this value exist. If such rows do exist, then Oracle Database returns an error.

You can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "UNUSABLE LOCAL INDEXES Clauses".

Restriction on Modifying List Subpartitions

The only *modify_LOB_parameters* you can specify for *subpartition* are the *allocate_extent_clause* and *deallocate_unused_clause*.

move_table_partition

Use the *move_table_partition* clause to move *partition* to another segment. You can move partition data to another tablespace, recluster data to reduce fragmentation, or change create-time physical attributes.

If the table contains LOB columns, then you can use the *LOB_storage_clause* to move the LOB data and LOB index segments associated with this partition. Only the LOBs named are affected. If you do not specify the *LOB_storage_clause* for a particular LOB column, then its LOB data and LOB index segments are not moved.

If the table contains nested table columns, then you can use the *nested_table_col_properties clause* of the *table_partition_description* to move the nested table segments associated with this partition. Only the nested table items named are affected. If you do not specify the *nested_table_col_properties clause* of the *table_partition_description* for a particular nested table column, then its segments are not moved.

Oracle Database moves local index partitions corresponding to the specified partition. If the moved partitions are not empty, then the database marks them UNUSABLE. The database

invalidates global indexes on heap-organized tables. You can update these indexes during this operation using the *update_index_clauses*.

When you move a LOB data segment, Oracle Database drops the old data segment and corresponding index segment and creates new segments even if you do not specify a new tablespace.

The move operation obtains its parallel attribute from the *parallel_clause*, if specified. When it is not specified, the default parallel attributes of the table, if any, are used. If neither is specified, then Oracle Database performs the move serially.

Specifying the *parallel_clause* in MOVE PARTITION does not change the default parallel attributes of *table*.

> **Note:**
>
> For index-organized tables, Oracle Database uses the address of the primary key, as well as its value, to construct logical rowids. The logical rowids are stored in the secondary index of the table. If you move a partition of an index-organized table, then the address portion of the rowids will change, which can hamper performance. To ensure optimal performance, rebuild the secondary index(es) on the moved partition to update the rowids.

> **See Also:**
>
> "Moving Table Partitions: Example"

MAPPING TABLE

The MAPPING TABLE clause is relevant only for an index-organized table that already has a mapping table defined for it. Oracle Database moves the mapping table along with the moved index-organized table partition. The mapping table partition inherits the physical attributes of the moved index-organized table partition. This is the only way you can change the attributes of the mapping table partition. If you omit this clause, then the mapping table partition retains its original attributes.

Oracle Database marks UNUSABLE all corresponding bitmap index partitions.

Refer to the *mapping_table_clauses* (in CREATE TABLE) for more information on this clause.

ONLINE

Specify ONLINE to indicate that DML operations on the table partition will be allowed while moving the table partition.

Restrictions on the ONLINE Clause

The ONLINE clause is subject to the following restrictions when moving table partitions:

- You cannot specify the ONLINE clause for tables owned by SYS.
- You cannot specify the ONLINE clause for index-organized tables.
- You cannot specify the ONLINE clause for heap-organized tables that contain object types or on which bitmap join indexes or domain indexes are defined.

- Parallel DML and direct path INSERT operations require an exclusive lock on the table. Therefore, these operations are not supported concurrently with an ongoing online partition MOVE, due to conflicting locks.

Restrictions on Moving Table Partitions

Moving table partitions is subject to the following restrictions:

- If *partition* is a hash partition, then the only attribute you can specify in this clause is TABLESPACE.
- You cannot specify this clause for a partition containing subpartitions. However, you can move subpartitions using the *move_table_subpartition* clause.

move_table_subpartition

Use the *move_table_subpartition* clause to move the subpartition identified by *subpartition_extended_name* to another segment. If you do not specify TABLESPACE, then the subpartition remains in the same tablespace.

If the subpartition is not empty, then Oracle Database marks UNUSABLE all local index subpartitions corresponding to the subpartition being moved. You can update all indexes on heap-organized tables during this operation using the *update_index_clauses*.

If the table contains LOB columns, then you can use the *LOB_storage_clause* to move the LOB data and LOB index segments associated with this subpartition. Only the LOBs specified are affected. If you do not specify the *LOB_storage_clause* for a particular LOB column, then its LOB data and LOB index segments are not moved.

When you move a LOB data segment, Oracle Database drops the old data segment and corresponding index segment and creates new segments even if you do not specify a new tablespace.

ONLINE

Specify ONLINE to indicate that DML operations on the table subpartition will be allowed while moving the table subpartition.

Restrictions on the ONLINE Clause

The ONLINE clause for moving table subpartitions is subject to the same restrictions as the ONLINE clause for moving table partitions. Refer to "Restrictions on the ONLINE Clause."

Restriction on Moving Table Subpartitions

The only clauses of the *partitioning_storage_clause* you can specify are the TABLESPACE clause and *table_compression*.

add_external_partition_attrs
Use this clause to add external parameters to a partitioned table.

add_table_partition

Use the *add_table_partition* clause to add one or more range, list, or system partitions to *table*, or to add one hash partition to *table*.

For each partition added, Oracle Database adds to any local index defined on *table* a new partition with the same name as that of the base table partition. If the index already has a partition with such a name, then Oracle Database generates a partition name of the form SYS_Pn.

If *table* is index organized, then for each partition added Oracle Database adds a partition to any mapping table and overflow area defined on the table as well.

If *table* is the parent table of a reference-partitioned table, then you can use the *dependent_tables_clause* to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

The default indexing property of *table* is inherited by the new table partition(s). You can override this by setting the indexing property of a list, range, or system partition using the *indexing_clause* in the *table_partition_description* clause, or a hash partition using the *indexing_clause* in the *add_hash_partition_clause*.

For each partition added to a composite-partitioned table, Oracle Database adds a new index partition with the same subpartition descriptions to all local indexes defined on *table*. Global indexes defined on *table* are not affected. If you specify the indexing property for the new table partition, then the new subpartitions inherit the indexing property for the partition. Otherwise, the new subpartitions inherit the default indexing property for the table. You can override this by setting the indexing property of a subpartition using the *indexing_clause* in the *range_subpartition_desc*, *individual_hash_subparts*, and *list_subpartition_desc* clauses.

BEFORE Clause

You can specify the optional BEFORE clause only when adding system partitions to *table*. This clause lets you specify where the new partition(s) should be added in relation to existing partitions. You cannot split a system partition. Therefore, this clause is useful if you want to divide the contents of one existing partition among multiple new partitions. If you omit this clause, then the database adds the new partition(s) after the existing partitions.

Restriction on Adding Table Partitions

If *table* is an index-organized table, or if a local domain index is defined on *table*, then you can add only one partition at a time.

> **See Also:**
>
> "Adding a Table Partition with a LOB and Nested Table Storage: Examples" and "Adding Multiple Partitions to a Table: Example"

add_range_partition_clause

The *add_range_partition_clause* lets you add a new range partition to the high end of a range-partitioned or composite range-partitioned table (after the last existing partition).

If a domain index is defined on *table*, then the index must not be marked IN_PROGRESS or FAILED.

Restrictions on Adding Range Partitions

Adding range partitions is subject to the following restrictions:

- If the upper partition bound of each partitioning key in the existing high partition is MAXVALUE, then you cannot add a partition to the table. Instead, use the *split_table_partition* clause to add a partition at the beginning or the middle of the table.

- The *prefix_compression* and OVERFLOW clauses, are valid only for a partitioned index-organized table. You can specify *prefix_compression* only if prefix compression is enabled at the table level. You can specify OVERFLOW only if the partitioned table already has an overflow segment.
- You cannot specify the PCTUSED parameter for the index segment of an index-organized table.

range_values_clause

Specify the upper bound for the new partition. The *value_list* is a comma-delimited, ordered list of literal values corresponding to the partitioning key columns. The *value_list* must collate greater than the partition bound for the highest existing partition in the table.

table_partition_description

Use this clause to specify any create-time physical attributes for the new partition. If the table contains LOB columns, then you can also specify partition-level attributes for one or more LOB items.

external_part_subpart_data_props

Starting with Oracle Database 12*c* Release 2 (12.2), Oracle supports partitioned and composite-partitioned external tables. When adding a partition to such a table, you can optionally use this clause to specify the DEFAULT DIRECTORY and LOCATION for the partition. Refer to DEFAULT DIRECTORY and LOCATION in the documentation on CREATE TABLE for the full semantics of these clauses.

Subpartition Descriptions

These clauses are valid only for composite-partitioned tables. Use the *range_subpartition_desc*, *list_subpartition_desc*, *individual_hash_subparts*, or *hash_subparts_by_quantity* clause as appropriate, if you want to specify subpartitions for the new partition. This clause overrides any subpartition descriptions defined in *subpartition_template* at the table level.

add_hash_partition_clause

The *add_hash_partition_clause* lets you add a new hash partition to the high end of a hash-partitioned table. Oracle Database populates the new partition with rows rehashed from other partitions of *table* as determined by the hash function. For optimal load balancing, the total number of partitions should be a power of 2.

You can specify a name for the partition, and optionally a tablespace where it should be stored. If you do not specify a name, then the database assigns a partition name of the form SYS_P*n*. If you do not specify TABLESPACE, then the new partition is stored in the default tablespace of the table. Other attributes are always inherited from table-level defaults.

If this operation causes data to be rehashed among partitions, then the database marks UNUSABLE any corresponding local index partitions. You can update all indexes on heap-organized tables during this operation using the *update_index_clauses*.

Use the *parallel_clause* to specify whether to parallelize the creation of the new partition.

Use the *read_only_clause* to put a table partition in read-only or read/write mode. Refer to the *read_only_clause* of CREATE TABLE for the full semantics of this clause.

Use the *indexing_clause* to specify the indexing property for the partition. If you do not specify this clause, then the partition inherits the default indexing property of *table*.

> **See Also:**
>
> CREATE TABLE and *Oracle Database VLDB and Partitioning Guide* for more information on hash partitioning

add_list_partition_clause

The *add_list_partition_clause* lets you add a new partition to *table* using a new set of partition values. You can specify any create-time physical attributes for the new partition. If the table contains LOB columns, then you can also specify partition-level attributes for one or more LOB items.

Restrictions on Adding List Partitions

You cannot add a list partition if you have already defined a DEFAULT partition for the table. Instead, you must use the *split_table_partition* clause to split the DEFAULT partition.

> **See Also:**
>
> - *list_partitions* of CREATE TABLE for more information and restrictions on list partitions
> - "Working with Default List Partitions: Example"

add_system_partition_clause

Use this clause to add a partition to a system-partitioned table. Oracle Database adds a corresponding index partition to all local indexes defined on the table.

The *table_partition_description* lets you specify partition-level attributes of the new partition. The values of any unspecified attributes are inherited from the table-level values.

Restriction on Adding System Partitions

You cannot specify the OVERFLOW clause when adding a system partition.

> **See Also:**
>
> The CREATE TABLE clause *system_partitioning* for more information on system partitions

coalesce_table_partition

COALESCE applies only to hash partitions. Use the *coalesce_table_partition* clause to indicate that Oracle Database should select the last hash partition, distribute its contents into one or more remaining partitions as determined by the hash function, and then drop the last partition.

Oracle Database drops local index partitions corresponding to the selected partition. The database marks UNUSABLE the local index partitions corresponding to one or more absorbing

partitions. The database invalidates any indexes on heap-organized tables. You can update all indexes during this operation using the *update_index_clauses*.

Restriction on Coalescing Table Partitions

If you update global indexes using the *update_all_indexes_clause*, then you can specify only the keywords `UPDATE INDEXES`, not the subclause.

drop_external_partition_attrs
Use this clause to drop external parameters in a partitioned table.

drop_table_partition

The *drop_table_partition* clause removes partitions, and the data in those partitions, from a partitioned table. If you want to drop a partition but keep its data in the table, then you must merge the partition into one of the adjacent partitions.

Starting with Oracle Database 12*c* Release 2 (12.2), you can use this clause to drop a partition from a partitioned table or composite-partitioned external table.

> **See Also:**
>
> *merge_table_partitions*

Use the *partition_extended_names* clause to specify one or more partitions to be dropped. When specifying multiple partitions, you must specify all partitions by name, as shown in the upper branch of the syntax diagram, or all partitions using the `FOR` clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one drop operation.

- If *table* has LOB columns, then Oracle Database also drops the LOB data and LOB index partitions and any subpartitions corresponding to the table partition(s) being dropped.
- If *table* has equipartitioned nested table columns, then Oracle Database also drops the nested table partitions corresponding to the table partition(s) being dropped.
- If *table* is index organized and has a mapping table defined on it, then the database drops the corresponding mapping table partition(s) as well.
- Oracle Database drops local index partitions and subpartitions corresponding to the dropped partition(s), even if they are marked `UNUSABLE`.

You can update indexes on *table* during this operation using the *update_index_clauses*. Updates to global indexes are metadata-only and the index entries for records that are dropped by the drop operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying `COALESCE CLEANUP` in the ALTER INDEX statement or in the *modify_index_partition* clause.

If you specify the *parallel_clause* with the *update_index_clauses*, then the database parallelizes the index update, not the drop operation.

If you drop a range partition and later insert a row that would have belonged to the dropped partition, then the database stores the row in the next higher partition. However, if that partition is the highest partition, then the insert will fail, because the range of values represented by the dropped partition is no longer valid for the table.

Restrictions on Dropping Table Partitions

Dropping table partitions is subject to the following restrictions:

- You cannot drop a partition of a hash-partitioned table. Instead, use the *coalesce_table_partition* clause.
- You cannot drop all of the partitions in a table. Instead, drop the table.
- If you update global indexes using the update_all_indexes_clause, then you can specify only the `UPDATE INDEXES` keywords but not the subclause.
- If *table* is an index-organized table, or if a local domain index is defined on *table*, then you can drop only one partition at a time.
- You cannot drop a partition of a duplicated table.
- Dropping a partition does not place the partition in the Oracle Database recycle bin, regardless of the setting of the recycle bin. Dropped partitions are immediately removed from the system.

> **See Also:**
>
> "Dropping a Table Partition: Example"

drop_table_subpartition

Use this clause to drop range or list subpartitions from a range, list, or hash composite-partitioned table. Oracle Database deletes any rows in the dropped subpartition(s).

Starting with Oracle Database 12*c* Release 2 (12.2), you can use this clause to drop a subpartition from a composite-partitioned external table.

Use the *subpartition_extended_names* clause to specify one or more subpartitions to be dropped. When specifying multiple subpartitions, you must specify all subpartitions by name, as shown in the upper branch of the syntax diagram, or all subpartitions using the `FOR` clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one drop operation.

Oracle Database drops the corresponding subpartition(s) of any local index. Other index subpartitions are not affected. Any global indexes are marked `UNUSABLE` unless you specify the *update_global_index_clause* or *update_all_indexes_clause*. Updates to global indexes are metadata-only and the index entries for records that are dropped by the drop operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying `COALESCE CLEANUP` in the ALTER INDEX statement or in the *modify_index_partition* clause.

Restrictions on Dropping Table Subpartitions

Dropping table subpartitions is subject to the following restrictions:

- You cannot drop a hash subpartition. Instead use the `MODIFY PARTITION ... COALESCE SUBPARTITION` syntax.
- You cannot drop all of the subpartitions in a partition. Instead, use the *drop_table_partition* clause.
- If you update the global indexes, then you cannot specify the optional subclause of the *update_all_indexes_clause*.
- If *table* is an index-organized table, then you can drop only one subpartition at a time.

- When dropping multiple subpartitions, all of the subpartitions must be in the same partition.
- You cannot drop a subpartition of a duplicated table.

rename_partition_subpart

Use the *rename_partition_subpart* clause to rename a table partition or subpartition to *new_name*. For both partitions and subpartitions, *new_name* must be different from all existing partitions and subpartitions of the same table.

If *table* is index organized, then Oracle Database assigns the same name to the corresponding primary key index partition as well as to any existing overflow partitions and mapping table partitions.

Starting with Oracle Database 12*c* Release 2 (12.2), you can use this clause to rename a partition or subpartition in a partitioned or composite-partitioned external table.

> **See Also:**
>
> "Renaming Table Partitions: Examples"

truncate_partition_subpart

Specify TRUNCATE *partition_extended_names* to remove all rows from the partition(s) identified by *partition_extended_names* or, if the table is composite partitioned, all rows from the subpartitions of those partitions. Specify TRUNCATE *subpartition_extended_names* to remove all rows from individual subpartitions. If *table* is index organized, then Oracle Database also truncates any corresponding mapping table partitions and overflow area partitions.

When specifying multiple partitions, you must specify all partitions by name, as shown in the upper branch of the *partition_extended_names* syntax diagram, or all partitions using the FOR clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one truncate operation. The same rule applies when specifying multiple subpartitions with the subpartition_extended_names clause.

For each specified partition or subpartition:

- If the partition or subpartition to be truncated contain data, then you must first disable any referential integrity constraints on the table. Alternatively, you can delete the rows and then truncate the partition.
- If *table* contains any LOB columns, then the LOB data and LOB index segments for the partition are also truncated. If *table* is composite partitioned, then the LOB data and LOB index segments for the subpartitions of the partition are truncated.
- If *table* contains any equipartitioned nested tables, then you cannot truncate the parent partition unless its corresponding nested table partition is empty.
- If a domain index is defined on *table*, then the index must not be marked IN_PROGRESS or FAILED, and the index partition corresponding to the table partition being truncated must not be marked IN_PROGRESS.

For each partition or subpartition truncated, Oracle Database also truncates corresponding local index partitions and subpartitions. If those index partitions or subpartitions are marked UNUSABLE, then the database truncates them and resets the UNUSABLE marker to VALID.

You can update indexes on *table* during this operation using the *update_index_clauses*. Updates to global indexes are metadata-only and the index entries for records that are

dropped by the truncate operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying `COALESCE CLEANUP` in the ALTER INDEX statement or in the *modify_index_partition* clause.

If you specify the *parallel_clause* with the *update_index_clauses*, then the database parallelizes the index update, not the truncate operation.

DROP STORAGE

Specify `DROP STORAGE` to deallocate all space from the deleted rows, except the space allocated by the `MINEXTENTS` parameter. This space can subsequently be used by other objects in the tablespace.

DROP ALL STORAGE

Specify `DROP ALL STORAGE` to deallocate all space from the deleted rows, including the space allocated by the `MINEXTENTS` parameter. All segments for the partition(s) or subpartition(s), as well as all segments for their dependent objects, will be deallocated.

Restrictions on DROP ALL STORAGE

This clause is subject to the same restrictions as described in "Restrictions on Deferred Segment Creation".

REUSE STORAGE

Specify `REUSE STORAGE` to keep space from the deleted rows allocated to the partition(s) or subpartition(s). The space is subsequently available only for inserts and updates to the same partition(s) or subpartition(s).

CASCADE

Specify `CASCADE` to truncate the corresponding partition(s) or subpartition(s) in all reference-partitioned child tables of *table*.

Restrictions on Truncating Table Partitions and Subpartitions

Truncating table partitions and subpartitions is subject to the following restrictions:

- If you update global indexes using the *update_all_indexes_clause*, then you can specify only the `UPDATE INDEXES` keywords, not the subclause.
- If *table* is an index-organized table, or if a local domain index is defined on *table*, then you can truncate only one table partition or one table subpartition at a time.
- You cannot truncate partitions or subpartitions in a duplicated table.

> **See Also:**
>
> "Truncating Table Partitions: Example"

split_table_partition

The *split_table_partition* clause lets you create, from the partition identified by *partition_extended_name*, multiple new partitions, each with a new segment, new physical attributes, and new initial extents. The segment associated with the current partition is discarded.

The new partitions inherit all unspecified physical attributes from the current partition.

> **Note:**
>
> Oracle Database can optimize and speed up `SPLIT PARTITION` and `SPLIT SUBPARTITION` operations if specific conditions are met. Refer to *Oracle Database VLDB and Partitioning Guide* for information on optimizing these operations.

- If you split a `DEFAULT` list partition, then the last resulting partition will have the `DEFAULT` value. All other resulting partitions will have the specified split values.
- If *`table`* is index organized, then Oracle Database splits any corresponding mapping table partition and places it in the same tablespace as the parent index-organized table partition. The database also splits any corresponding overflow area, and you can use the `OVERFLOW` clause to specify segment attributes for the new overflow areas.
- If *`table`* contains LOB columns, then you can use the *`LOB_storage_clause`* to specify separate LOB storage attributes for the LOB data segments resulting from the split. The database drops the LOB data and LOB index segments of the current partition and creates new segments for each LOB column, for each partition, even if you do not specify a new tablespace.
- If *`table`* contains nested table columns, then you can use the *`split_nested_table_part`* clause to specify the storage table names and segment attributes of the nested table segments resulting from the split. The database drops the nested table segments of the current partition and creates new segments for each nested table column, for each partition. This clause allows for multiple nested table columns in the parent table as well as multilevel nested table columns.

Oracle Database splits the corresponding local index partition, even if it is marked `UNUSABLE`. The database marks `UNUSABLE`, and you must rebuild the local index partitions corresponding to the split partitions. The new index partitions inherit their attributes from the partition being split. The database stores the new index partitions in the default tablespace of the index partition being split. If that index partition has no default tablespace, then the database uses the tablespace of the new underlying table partitions.

AT Clause

The `AT` clause applies only to range partitions and lets you split one range partition into two range partitions. Specify the new noninclusive upper bound for the first of the two new partitions. The value list must compare less than the original partition bound for the current partition and greater than the partition bound for the next lowest partition (if there is one).

VALUES Clause

The `VALUES` clause applies only to list partitions and allows you to split one list partition into two list partitions. If the table is partitioned on one key column, then use the upper branch of the *`list_values`* syntax to specify a list of values for that column. You can specify `NULL` if you have not already specified `NULL` for another partition in the table. If the table is partitioned on multiple key columns, then use the lower branch of the *`list_values`* syntax to specify a list of value lists. Each value list is enclosed in parentheses and represents a list of values for the key columns. Oracle Database creates the first new partition using the *`list_values`* you specify and creates the second new partition using the remaining partition values from the current partition. Therefore, the value list cannot contain all of the partition values of the current partition, nor can it contain any partition values that do not already exist for the current partition.

INTO Clause

The INTO clause lets you describe the new partitions resulting from the split.

- The AT ... INTO clause lets you describe the partitions resulting from splitting one range partition into two range partitions. In *range_partition_desc*, the keyword PARTITION is required even if you do not specify the optional names and physical attributes of the two partitions resulting from the split. If you do not specify new partition names, then Oracle Database assigns names of the form SYS_Pn. Any attributes you do not specify are inherited from the current partition.
- The VALUES ... INTO clause lets you describe the partitions resulting from splitting one list partition into two list partitions. In *list_partition_desc*, the keyword PARTITION is required even if you do not specify the optional names and physical attributes of the two partitions resulting from the split. If you do not specify new partition names, then Oracle Database assigns names of the form SYS_Pn. Any attributes you do not specify are inherited from the current partition.
- The INTO clause lets you split one range partition into two or more range partitions, or one list partition into two or more list partitions. If you do not specify new partition names, then Oracle Database assigns names of the form SYS_Pn. Any attributes you do not specify are inherited from the current partition.
  - You must specify range partitions in ascending order of their partition bounds. The partition bound of the first specified range partition must be greater than the partition bound for the next lowest partition in the table (if there is one). Do not specify a partition bound for the last range partition; it will inherit the partition bound of the current partition.
  - For list partitions, all specified partition values for the new partitions must exist in the current partition. Do not specify any partition values for the last partition. Oracle Database creates the last partition using the remaining partition values from the current partition.

For range-hash composite-partitioned tables, if you specify subpartitioning for the new partitions, then you can specify only TABLESPACE and table compression for the subpartitions. All other attributes are inherited from the current partition. If you do not specify subpartitioning for the new partitions, then their tablespace is also inherited from the current partition.

For range-list and list-list composite-partitioned tables, you cannot specify subpartitions for the new partitions at all. The list subpartitions of the split partition inherit the number of subpartitions and value lists from the current partition.

For all composite-partitioned tables for which you do not specify subpartition names for the newly created subpartitions, the newly created subpartitions inherit their names from the parent partition as follows:

- For those subpartitions in the parent partition with names of the form *partition_name* underscore (_) *subpartition_name* (for example, P1_SUBP1), Oracle Database generates corresponding names in the newly created subpartitions using the new partition names (for example P1A_SUB1 and P1B_SUB1).
- For those subpartitions in the parent partition with names of any other form, Oracle Database generates subpartition names of the form SYS_SUBP*n*.

Oracle Database splits the corresponding partition(s) in each local index defined on *table*, even if the index is marked UNUSABLE.

If *table* is the parent table of a reference-partitioned table, then you can use the *dependent_tables_clause* to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

Oracle Database invalidates any indexes on heap-organized tables. You can update these indexes during this operation using the *update_index_clauses*.

The *parallel_clause* lets you parallelize the split operation but does not change the default parallel attributes of the table.

ONLINE

Specify ONLINE to indicate that DML operations on the table will be allowed while splitting the table partition.

Restrictions on the ONLINE Clause

The ONLINE clause is subject to the following restrictions when splitting table partitions:

- You cannot specify the ONLINE clause for tables owned by SYS.
- You cannot specify the ONLINE clause for index-organized tables.
- You cannot specify the ONLINE clause if a domain index is defined on the table.
- You cannot specify the ONLINE clause for heap-organized tables that contain object types or on which bitmap join indexes are defined.
- Parallel DML and direct path INSERT operations require an exclusive lock on the table. Therefore, these operations are not supported concurrently with an ongoing online partition split, due to conflicting locks.

Restrictions on Splitting Table Partitions

Splitting table partitions is subject to the following restrictions:

- You cannot specify this clause for a hash partition.
- You cannot specify the *parallel_clause* for index-organized tables.
- If *table* is an index-organized table, or if a local domain index is defined on *table*, then you can split the partition into only two new partitions.

> **See Also:**
>
> "Splitting Table Partitions: Examples"

split_table_subpartition

Use this clause to split a subpartition into multiple new subpartitions with nonoverlapping value lists.

> **Note:**
>
> Oracle Database can optimize and speed up SPLIT PARTITION and SPLIT SUBPARTITION operations if specific conditions are met. Refer to *Oracle Database VLDB and Partitioning Guide* for information on optimizing these operations.

AT Clause

The AT clause is valid only for range subpartitions. Specify the new noninclusive upper bound for the first of the two new subpartitions. The value list must compare less than the original subpartition bound for the subpartition identified by *subpartition_extended_name* and greater than the partition bound for the next lowest subpartition (if there is one).

VALUES Clause

The VALUES clause is valid only for list subpartitions. If the table is subpartitioned on one key column, then use the upper branch of the *list_values* syntax to specify a list of values for that column. You can specify NULL if you have not already specified NULL for another subpartition in the same partition. If the table is subpartitioned on multiple key columns, then use the lower branch of the *list_values* syntax to specify a list of value lists. Each value list is enclosed in parentheses and represents a list of values for the key columns. Oracle Database creates the first new subpartition using the subpartition value list you specify and creates the second new partition using the remaining partition values from the current subpartition. Therefore, the value list cannot contain all of the partition values of the current subpartition, nor can it contain any partition values that do not already exist for the current subpartition.

INTO Clause

The INTO clause lets you describe the new subpartitions resulting from the split.

- The AT ... INTO clause lets you describe the two subpartitions resulting from splitting one range partition into two range partitions. In *range_subpartition_desc*, the keyword SUBPARTITION is required even if you do not specify the optional names and attributes of the two new subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form SYS_SUBP*n* Any attributes you do not specify are inherited from the current subpartition.
- The VALUES ... INTO clause lets you describe the two subpartitions resulting from splitting one list partition into two list partitions. In *list_subpartition_desc*, the keyword SUBPARTITION is required even if you do not specify the optional names and attributes of the two new subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form SYS_SUBP*n* Any attributes you do not specify are inherited from the current subpartition.
- The INTO clause lets you split one range subpartition into two or more range subpartitions, or one list subpartition into two or more list subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form SYS_SUBP*n*. Any attributes you do not specify are inherited from the current subpartition.
  - You must specify range subpartitions in ascending order of their subpartition bounds. The subpartition bound of the first specified range subpartition must be greater than the subpartition bound for the next lowest subpartition (if there is one). Do not specify a subpartition bound for the last range subpartition; it will inherit the partition bound of the current subpartition.
  - For list subpartitions, all specified subpartition values for the new subpartitions must exist in the current subpartition. Do not specify any subpartition values for the last subpartition. Oracle Database creates the last subpartition using the remaining partition values from the current subpartition.

Oracle Database splits any corresponding local subpartition index, even if it is marked UNUSABLE. The new index subpartitions inherit the names of the new table subpartitions unless those names are already held by index subpartitions. In that case, the database assigns new index subpartition names of the form SYS_SUBPn. The new index subpartitions inherit physical attributes from the parent subpartition. However, if the parent subpartition does not have a default TABLESPACE attribute, then the new subpartitions inherit the tablespace of the corresponding new table subpartitions.

Oracle Database invalidates indexes on heap-organized tables. You can update these indexes by using the *update_index_clauses*.

ONLINE

Specify `ONLINE` to indicate that DML operations on the table will be allowed while splitting the table subpartition.

Restrictions on the ONLINE Clause

The `ONLINE` clause for splitting table subpartitions is subject to the same restrictions as the `ONLINE` clause for splitting table partitions. Refer to Restrictions on the ONLINE Clause.

Restrictions on Splitting Table Subpartitions

Splitting table subpartitions is subject to the following restrictions:

- You cannot specify this clause for a hash subpartition.
- In subpartition descriptions, the only clauses of *partitioning_storage_clause* you can specify are `TABLESPACE` and table compression.
- You cannot specify the *parallel_clause* for index-organized tables.
- If *table* is an index-organized table, then you can split the subpartition into only two new subpartitions.

merge_table_partitions

The *merge_table_partitions* clause lets you merge the contents of two or more range, list, or system partitions of *table* into one new partition and then drop the original partitions. This clause is not valid for hash partitions. Use the *coalesce_table_partition* clause instead.

Specify a comma-separated list of two or more range, list, or system partitions to be merged. You can use the `TO` clause to specify two or more adjacent range partitions to be merged.

For each partition, use *partition* to specify a partition name or the `FOR` clause to specify a partition without using its name. See "References to Partitioned Tables and Indexes " for more information on the `FOR` clause.

- The partitions to be merged must be adjacent and must be specified in ascending order of their partition bounds if they are range partitions. List partitions and system partitions need not be adjacent in order to be merged.
- When you merge range partitions, the new partition inherits the partition bound of the highest of the original partitions.
- When you merge list partitions, the resulting partition value list is the union of the set of the partition values lists of the partitions being merged. If you merge a `DEFAULT` list partition with other list partitions, then the resulting partition will be the `DEFAULT` partition and will have the `DEFAULT` value.
- When you merge composite range partitions or composite list partitions, range-list or list-list composite partitions, you cannot specify subpartition descriptions. Oracle Database obtains the subpartitioning information from the subpartition template. If you have not specified a subpartition template, then the database creates one `MAXVALUE` subpartition from range subpartitions or one `DEFAULT` subpartition from list subpartitions.

Any attributes you do not specify explicitly for the new partition are inherited from table-level defaults. However, if you reuse one of the partition names for the new partition, then the new partition inherits values from the partition whose name is being reused rather than from table-level default values.

Oracle Database drops local index partitions corresponding to the selected partitions and marks UNUSABLE the local index partition corresponding to merged partition. The database also marks UNUSABLE any global indexes on heap-organized tables. You can update all these indexes during this operation using the *update_index_clauses*.

If *table* is the parent table of a reference-partitioned table, then you can use the *dependent_tables_clause* to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

ONLINE

Specify ONLINE to allow DML operations on the table partitions during the merge partitions operation.

Restriction on Merging Table Partitions

If *table* is an index-organized table, or if a local domain index is defined on *table*, then you can merge only two partitions at a time.

> **See Also:**
>
> "Merging Two Table Partitions: Example", "Merging Four Adjacent Range Partitions: Example", and "Working with Default List Partitions: Example"

merge_table_subpartitions

The *merge_table_subpartitions* clause lets you merge the contents of two or more range or list subpartitions of *table* into one new subpartition and then drop the original subpartitions. This clause is not valid for hash subpartitions. Use the *coalesce_hash_subpartition* clause instead.

Specify a comma-separated list of two or more range or list subpartitions to be merged. You can use the TO clause to specify two or more adjacent range subpartitions to be merged.

For each subpartition, use *subpartition* to specify a subpartition name or the FOR clause to specify a subpartition without using its name. See "References to Partitioned Tables and Indexes " for more information on the FOR clause.

The subpartitions to be merged must belong to the same partition. If they are range subpartitions, then they must be adjacent. If they are list subpartitions, then they need not be adjacent. The data in the resulting subpartition consists of the combined data from the merged subpartitions.

If you specify the INTO clause, then in the *range_subpartition_desc* or *list_subpartition_desc* you cannot specify the *range_values_clause* or *list_values_clause*, respectively. Further, the only clauses you can specify in the *partitioning_storage_clause* are the TABLESPACE clause and *table_compression*.

Any attributes you do not specify explicitly for the new subpartition are inherited from partition-level values. However, if you reuse one of the subpartition names for the new subpartition, then the new subpartition inherits values from the subpartition whose name is being reused rather than from partition-level default values.

Oracle Database merges corresponding local index subpartitions and marks the resulting index subpartition UNUSABLE. The database also marks UNUSABLE both partitioned and nonpartitioned

global indexes on heap-organized tables. You can update all indexes during this operation using the *update_index_clauses*.

ONLINE

Specify `ONLINE` to allow DML operations on the table subpartitions during the merge subpartitions operation.

Restriction on Merging Table Subpartitions

If *`table`* is an index-organized table, then you can merge only two subpartitions at a time.

exchange_partition_subpart

Use the `EXCHANGE PARTITION` or `EXCHANGE SUBPARTITION` clause to exchange the data and index segments of:

- One nonpartitioned table with:
  - one range, list, or hash partition
  - one range, list, or hash subpartition
- One range-partitioned table with the range subpartitions of a range-range or list-range composite-partitioned table partition
- One hash-partitioned table with the hash subpartitions of a range-hash or list-hash composite-partitioned table partition
- One list-partitioned table with the list subpartitions of a range-list or hash-list composite-partitioned table partition

In all cases, the structure of the table and the partition or subpartition being exchanged, including their partitioning keys, must be identical. In the case of list partitions and subpartitions, the corresponding value lists must also match.

This clause facilitates high-speed data loading when used with transportable tablespaces.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information on transportable tablespaces

If *`table`* contains LOB columns, then for each LOB column Oracle Database exchanges LOB data and LOB index partition or subpartition segments with corresponding LOB data and LOB index segments of *`table`*.

If *`table`* has nested table columns, then for each such column Oracle Database exchanges nested table partition segments with corresponding nested table segments of the nonpartitioned table.

If *`table`* contains an identity column, then so must the partition or subpartition being exchanged, and vice versa. The sequence generators must both be increasing or decreasing. The sequence generators are not exchanged, so *`table`* and the partition or subpartition will continue to use the same sequence generators. The high water mark for both sequence generators will be adjusted so that new identity column values will not conflict with existing values.

All of the segment attributes of the two objects (including tablespace and logging) are also exchanged.

Existing statistics for the table being exchanged into the partitioned table will be exchanged. However, the global statistics for the partitioned table will not be altered. Use the `DBMS_STATS.GATHER_TABLE_STATS` procedure to re-create global statistics. You can set the `GRANULARITY` attribute equal to '`APPROX_GLOBAL AND PARTITION`' to speed up the process and aggregate new global statistics based on the existing partition statistics. See *Oracle Database PL/SQL Packages and Types Reference* for more information on this packaged procedure.

Oracle Database invalidates any global indexes on the objects being exchanged. You can update the global indexes on the table whose partition is being exchanged by using either the update_global_index_clause or the update_all_indexes_clause. For the *update_all_indexes_clause*, you can specify only the keywords `UPDATE INDEXES`, not the subclause. Global indexes on the table being exchanged remain invalidated. The *update_global_index_clause* and *update_all_indexes_clause* do not update local indexes during an exchange operation. You can specify local index maintenance by using the INCLUDING | EXCLUDING INDEXES clause. If you specify the *parallel_clause* with either of these clauses, then the database parallelizes the index update, not the exchange operation.

> **See Also:**
>
> "Notes on Exchanging Partitions and Subpartitions"

WITH TABLE

Specify the *table* with which the partition or subpartition will be exchanged. If you omit *schema*, then Oracle Database assumes that *table* is in your own schema.

INCLUDING | EXCLUDING INDEXES

Specify `INCLUDING INDEXES` if you want local index partitions or subpartitions to be exchanged with the corresponding table index (for a nonpartitioned table) or local indexes (for a hash-partitioned table). Specify `EXCLUDING INDEXES` if you want all index partitions or subpartitions corresponding to the partition and all the regular indexes and index partitions on the exchanged table to be marked `UNUSABLE`. If you omit this clause, then the default is `EXCLUDING INDEXES`.

WITH | WITHOUT VALIDATION

Specify `WITH VALIDATION` if you want Oracle Database to return an error if any rows in the exchanged table do not map into partitions or subpartitions being exchanged. Specify `WITHOUT VALIDATION` if you do not want Oracle Database to check the proper mapping of rows in the exchanged table. If you omit this clause, then the default is `WITH VALIDATION`.

exceptions_clause

See "Handling Constraint Exceptions " for information on this clause. In the context of exchanging partitions, this clause is valid only if the partitioned table has been defined with a `UNIQUE` constraint, and that constraint must be in `DISABLE VALIDATE` state. This clause is valid only for exchanging partition, not subpartitions.

CASCADE

Specify `CASCADE` to exchange the corresponding partition or subpartition in all reference-partitioned child tables of *table*. The reference-partitioned table hierarchies of the source and target must match.

Restrictions on CASCADE

The following restrictions apply to the `CASCADE` clause:

- You cannot specify `CASCADE` if a parent key in the reference-partitioned table hierarchy is referenced by multiple partitioning constraints.
- You cannot specify `CASCADE` if a domain index or an `XMLIndex` index is defined on any of the reference-partitioned child tables of *`table`*.

> **See Also:**
>
> - The `DBMS_IOT` package in *Oracle Database PL/SQL Packages and Types Reference* for information on the SQL scripts
> - *Oracle Database Administrator's Guide* for information on eliminating migrated and chained rows
> - *constraint* for more information on constraint checking and "Creating an Exceptions Table for Index-Organized Tables: Example"

Notes on Exchanging Partitions and Subpartitions

The following notes apply when exchanging partitions and subpartitions:

- Both tables involved in the exchange must have the same primary key, and no validated foreign keys can be referencing either of the tables unless the referenced table is empty.
- When exchanging partitioned index-organized tables:
  - The source and target table or partition must have their primary key set on the same columns, in the same order.
  - If prefix compression is enabled, then it must be enabled for both the source and the target, and with the same prefix length.
  - Both the source and target must be index organized.
  - Both the source and target must have overflow segments, or neither can have overflow segments. Also, both the source and target must have mapping tables, or neither can have a mapping table.
  - Both the source and target must have identical storage attributes for any LOB columns.

> **See Also:**
>
> "Exchanging Table Partitions: Example"

dependent_tables_clause

This clause is valid only when you are altering the parent table of a reference-partitioned table. The clause lets you specify attributes of partitions that are created by the operation for reference-partitioned child tables of the parent table.

- If the parent table is not composite partitioned, then specify one or more child tables, and for each child table specify one *`partition_spec`* for each partition created in the parent table.

- If the parent table is composite, then specify one or more child tables, and for each child table specify one *partition_spec* for each subpartition created in the parent table.

> **See Also:**
>
> The CREATE TABLE clause *reference_partitioning* for information on creating reference-partitioned tables and *Oracle Database VLDB and Partitioning Guide* for information on partitioning by reference in general

UNUSABLE LOCAL INDEXES Clauses

These two clauses modify the attributes of local index partitions and index subpartitions corresponding to *partition*, depending on whether you are modifying a partition or subpartition.

- UNUSABLE LOCAL INDEXES marks UNUSABLE the local index partition or index subpartition associated with *partition*.
- REBUILD UNUSABLE LOCAL INDEXES rebuilds the unusable local index partition or index subpartition associated with *partition*.

Restrictions on UNUSABLE LOCAL INDEXES

This clause is subject to the following restrictions:

- You cannot specify this clause with any other clauses of the *modify_table_partition* clause.
- You cannot specify this clause in the *modify_table_partition* clause for a partition that has subpartitions. However, you can specify this clause in the *modify_table_subpartition* clause.

update_index_clauses

Use the *update_index_clauses* to update the indexes on *table* as part of the table partitioning operation. When you perform DDL on a table partition, if an index is defined on *table*, then Oracle Database invalidates the entire index, not just the partitions undergoing DDL. This clause lets you update the index partition you are changing during the DDL operation, eliminating the need to rebuild the index after the DDL.

The *update_index_clauses* are not needed, and are not valid, for partitioned index-organized tables. Index-organized tables are primary key based, so Oracle can keep global indexes USABLE during operations that move data but do not change its value.

update_global_index_clause

Use this clause to update only global indexes on *table*. Oracle Database marks UNUSABLE all local indexes on *table*.

UPDATE GLOBAL INDEXES

Specify UPDATE GLOBAL INDEXES to update the global indexes defined on *table*.

Restriction on Updating Global Indexes

If the global index is a global domain index defined on a LOB column, then Oracle Database marks the domain index UNUSABLE instead of updating it.

INVALIDATE GLOBAL INDEXES

Specify `INVALIDATE GLOBAL INDEXES` to invalidate the global indexes defined on *`table`*.

If you specify neither, then Oracle Database invalidates the global indexes.

Restrictions on Invalidating Global Indexes

This clause is supported only for global indexes. It is not supported for index-organized tables. In addition, this clause updates only indexes that are `USABLE` and `VALID`. `UNUSABLE` indexes are left unusable, and `INVALID` global indexes are ignored.

update_all_indexes_clause

Use this clause to update all indexes on *`table`*.

update_index_partition

This clause is valid only for operations on table partitions and affects only local indexes.

- The *`index_partition_description`* lets you specify physical attributes, tablespace storage, and logging for each partition of each local index. If you specify only the `PARTITION` keyword, then Oracle Database updates the index partition as follows:
  - For operations on a single table partition (such as `MOVE PARTITION` and `SPLIT PARTITION`), the corresponding index partition inherits the attributes of the affected index table partition, Oracle Database does not generate names for new index partitions, so any new index partitions resulting from this operation inherit their names from the corresponding new table partition.
  - For `MERGE PARTITION` operations, the resulting local index partition inherits its name from the resulting table partition and inherits its attributes from the local index.

  For a domain index, you can use the `PARAMETERS` clause to specify the parameter string that is passed uninterpreted to the appropriate ODCI indextype routine. The `PARAMETERS` clause is valid only for domain indexes, and is the only part of the *`index_partition_description`* you can specify for a domain index.

  > **See Also:**
  >
  > *Oracle Database Data Cartridge Developer's Guide* for more information on domain indexes

- For a composite-partitioned index, the *`index_subpartition_clause`* lets you specify tablespace storage for each subpartition. Refer to the index_subpartition_clause (in `CREATE INDEX`) for more information on this component of the *`update_index_partition`* clause.

For information on the `USABLE` and `UNUSABLE` keywords, refer to `ALTER INDEX` ... USABLE | UNUSABLE.

update_index_subpartition

This clause is valid only for operations on subpartitions of composite-partitioned tables and affects only local indexes on composite-partitioned tables. It lets you specify tablespace storage for one or more subpartitions.

Restrictions on Updating All Indexes

The following restrictions apply to the *`update_all_indexes_clause`*:

- You cannot specify this clause for index-organized tables.
- When you exchange a partition or subpartition with the *exchange_partition_subpart* clause, the *update_all_indexes_clause* is applicable only to global indexes. Therefore, you cannot specify the *update_index_partition* or *update_index_subpartition* clauses. You can, however, specify local index maintenance during an exchange operation by using the INCLUDING | EXCLUDING INDEXES clause.

> **See Also:**
>
> "Updating Global Indexes: Example" and "Updating Partitioned Indexes: Example"

parallel_clause

The *parallel_clause* lets you change the default degree of parallelism for queries and DML on the table.

For complete information on this clause, refer to *parallel_clause* in the documentation on CREATE TABLE.

Restrictions on Changing Table Parallelization

Changing parallelization is subject to the following restrictions:

- If *table* contains any columns of LOB or user-defined object type, then subsequent INSERT, UPDATE, and DELETE operations on *table* are executed serially without notification. Subsequent queries, however, are executed in parallel.
- If you specify the *parallel_clause* in conjunction with the *move_table_clause*, then the parallelism applies only to the move, not to subsequent DML and query operations on the table.

> **See Also:**
>
> "Specifying Parallel Processing: Example"

alter_table_partitionset

The clauses of *alter_table_partitionset* only apply to sharded tables within a composite sharding setup.

The following notes apply when changing table partitioning of sharded tables:

- Specify *add_partitionset* only to root sharded tables.
- For add and split partitionset operations you must deploy a new primary shardspace per partitionset before specifying *add_partitionset* .
- For add and split partitionset operations partition names do not have a value list after them. This is different from partition by list.
- Specify *modify_partitionset* only to root sharded tables that are partitioned by list.
- You must provide all the partitionset names as these are not generated by the system.

split_partitionset

Use *split_partitionset* to split an existing partitionset into one or more partitionsets. This clause is valid only for root sharded table in a composite sharding setup. New primary shardspaces must be deployed per new partitionset before executing *split_partitionset*.

See Operations on Directory-Based Partitioned Table for examples.

add_partitionset

add_partitionset clause is only valid for a root sharded table in a composite sharding setup. When a new primary shardspace is created, *add_partitionset* needs to be used to create new partitionsets.

See Operations on Directory-Based Partitioned Table for examples.

modify_partitionset

modify_partitionset clause is only value for a root sharded table that is partitionset by LIST. Use this clause to add a new list value to an existing partitionset.

move_partitionset

Use *move_partitionset* to move all existing partitions of a sharded table in a partitionset to new tablespace sets.

filter_condition

This clause lets you specify which rows to preserve during the following ALTER TABLE operations: moving, splitting, or merging table partitions or subpartitions; moving a table; or converting a nonpartitioned table to a partitioned table. The database preserves only the rows that satisfy the condition specified in the *where_clause*. Refer to the *where_clause* in the documentation on SELECT for the full semantics of this clause.

Restrictions on Filter Conditions

The following restrictions apply to the *filter_condition* clause:

- Filter conditions are supported only for heap-organized tables.
- Filter conditions can refer only to columns in the table being altered. Filter conditions cannot contain operations, such as joins or subqueries, that reference other database objects.
- Filter conditions are unsupported for tables with primary or unique keys that are referenced by enabled foreign keys.

Restrictions and Notes on Using Filter Conditions with Online Operations

The following restrictions and notes apply when you specify a filter condition for an online ALTER TABLE operation:

- You cannot specify both the *filter_condition* and ONLINE clauses if supplemental logging is enabled.
- When you specify both the *filter_condition* and ONLINE clauses, DML operations on the table are allowed during the ALTER TABLE operation. The filter condition does not have a direct effect on the concurrent DML operations. However, consider this combination carefully, because the filter operation and the DML operations could unintentionally conflict, as follows:

  - Inserts into a nonpartitioned table will succeed. Inserts into a partitioned table will succeed if they do not violate the partitioning key criteria.
  - Delete operations will apply only to rows that are preserved by the filter condition throughout the `ALTER TABLE` operation.
  - Update operations will apply only to rows that are preserved by the filter condition throughout the `ALTER TABLE` operation. These update operations will succeed, regardless of whether the update operation would have disqualified the rows for preservation by the filter condition.
  - Rows that do not qualify for preservation by the filter condition at the onset of the `ALTER TABLE` operation will not be preserved, regardless of whether an update operation would qualify the rows for preservation.

allow_disallow_clustering

This clause is valid for tables that use attribute clustering. It lets you allow or disallow attribute clustering for data movement that occurs during the move table operation specified by the *move_table_clause*, and the table partition and subpartition maintenance operations specified by the *coalesce_table_[sub]partition*, *merge_table_[sub]partitions*, *move_table_[sub]partition*, and *split_table_[sub]partition* clauses.

- Specify `ALLOW CLUSTERING` to allow attribute clustering for data movement. This clause overrides a `NO ON DATA MOVEMENT` setting in the DDL that created or altered the table.
- Specify `DISALLOW CLUSTERING` to disallow attribute clustering for data movement. This clause overrides a `YES ON DATA MOVEMENT` setting in the DDL that created or altered the table.

The *allow_disallow_clustering* clause has no effect if you specify it for a table that does not use attribute clustering.

> **See Also:**
>
> clustering_when clause of `CREATE TABLE` for more information on the `NO ON DATA MOVEMENT` and `YES ON DATA MOVEMENT` clauses

{ DEFERRED | IMMEDIATE } INVALIDATION

This clause lets you control when the database invalidates dependent cursors while performing table partition maintenance operations.

- If you specify `DEFERRED INVALIDATION`, then the database avoids or defers invalidating dependent cursors, when possible.
- If you specify `IMMEDIATE INVALIDATION`, then the database immediately invalidates dependent cursors, as it did in Oracle Database 12*c* Release 1 (12.1) and prior releases. This is the default.

If you omit this clause, then the value of the `CURSOR_INVALIDATION` initialization parameter determines when cursors are invalidated.

You can specify this clause only when performing table partition maintenance operations; it is not supported for any other `ALTER TABLE` operations.

> **See Also:**
>
> - *Oracle Database SQL Tuning Guide* for more information on cursor invalidation
> - *Oracle Database Reference* for more information in the `CURSOR_INVALIDATION` initialization parameter

move_table_clause

The *move_table_clause* lets you relocate data of a nonpartitioned or partitioned table into new segments. Alternatively you can move a partition or subpartition of a partitioned table into a new segment, optionally in a different tablespace, and optionally modify any of its storage attributes.

You can also move any LOB data segments associated with the table or partition using the *LOB_storage_clause* and *varray_col_properties* clause. LOB items not specified in this clause are not moved.

Moving Partitions and Subpartitions of Heap-Organized Tables

You can move all the partitions and subpartitions of a partitioned heap-organized table with a single `ALTER TABLE MOVE` statement.

Existing partition and subpartition properties that are not modified on table level will be preserved. For example, if you specify `COMPRESS` for the `ALTER TABLE MOVE` command, then all partitions will be compressed, whereas the tablespace location for each partition will be preserved. Conversely, if you specify a target tablespace for the `ALTER TABLE MOVE` , then all partitions will reside in the specified tablespace after the move, but the individual compression attribute for each partition will be preserved.

Restrictions on Moving All Partitions and Subpartions of a Partitioned Table with One Command

- You cannot use this functionality if a domain index is defined on the table.
- You cannot use this functionality if the table has columns of type `VARRAY`.
- You cannot change the attribute clustering properties.
- You can only control table-level segment attributes_clauses, such as tablespace or compression. Any segment attribute that is managed as default on the table-level is not supported.
- You cannot use this functionality for an index-organized table .

ONLINE Clause

Specify `ONLINE` if you want DML operations on the table to be allowed while the table is being moved.

Restrictions on Moving Tables Online

Moving tables online is subject to the following restrictions:

- You cannot combine this clause with any other clause in the same statement.
- You cannot specify this clause for a partitioned index-organized table.
- You cannot specify this clause if a domain index is defined on the table, like spatial, XML, or Text indexes.

- Parallel DML and direct path INSERT operations require an exclusive lock on the table. Therefore, these operations are not supported concurrently with an ongoing online table MOVE, due to conflicting locks.
- You cannot specify this clause for index-organized tables that contain any LOB, VARRAY, Oracle-supplied type, or user-defined object type columns.

index_org_table_clause

For an index-organized table, the *index_org_table_clause* of the *move_table_clause* lets you additionally specify overflow segment attributes. The *move_table_clause* rebuilds the primary key index of the index-organized table. The overflow data segment is not rebuilt unless the OVERFLOW keyword is explicitly stated, with two exceptions:

- If you alter the values of PCTTHRESHOLD or the INCLUDING column as part of this ALTER TABLE statement, then the overflow data segment is rebuilt.
- If you explicitly move any of out-of-line columns (LOBs, varrays, nested table columns) in the index-organized table, then the overflow data segment is also rebuilt.

The index and data segments of LOB columns are not rebuilt unless you specify the LOB columns explicitly as part of this ALTER TABLE statement.

mapping_table_clause

Specify MAPPING TABLE if you want Oracle Database to create a mapping table if one does not already exist. If it does exist, then the database moves the mapping table along with the index-organized table, and marks any bitmapped indexes UNUSABLE. The new mapping table is created in the same tablespace as the parent table.

Specify NOMAPPING to instruct the database to drop an existing mapping table.

Refer to *mapping_table_clauses* (in CREATE TABLE) for more information on this clause.

Restriction on Mapping Tables

You cannot specify NOMAPPING if any bitmapped indexes have been defined on *table*.

prefix_compression

Use the *prefix_compression* clause to enable or disable prefix compression in an index-organized table.

- COMPRESS enables prefix compression, which eliminates repeated occurrence 1of primary key column values in index-organized tables. Use *integer* to specify the prefix length (number of prefix columns to compress).

  The valid range of prefix length values is from 1 to the number of primary key columns minus 1. The default prefix length is the number of primary key columns minus 1.
- NOCOMPRESS disables prefix compression in index-organized tables. This is the default.

TABLESPACE *tablespace*

Specify the tablespace into which the rebuilt index-organized table is to be stored.

LOB_storage_clause

Use this clause to move a LOB segment to a different tablespace. You cannot use this clause to move a LOB segment if the table contains a LONG column. Instead, you must either convert the LONG column to a LOB, or you must export the table, re-create the table specifying the desired tablespace storage for the LOB column, and re-import the table data.

UPDATE INDEXES

This clause is valid only when performing online or offline moves of heap-organized tables. It allows you to update all global indexes on the table.

You can optionally change the tablespace for an index or index partition, as follows:

- Specify the *segment_attributes_clause* to change the tablespace of a nonpartitioned global index. Within this clause, you can specify only the TABLESPACE clause.
- Specify the *update_index_partition* clause to change the tablespace for a partition of a partitioned global index. Within this clause, you can specify only the TABLESPACE clause of the *segment_attributes_clause*.

Restrictions on Moving Tables

Moving tables is subject to the following restrictions:

- If you specify MOVE, then it must be the first clause in the ALTER TABLE statement, and the only clauses outside this clause that are allowed are the *physical_attributes_clause*, the *parallel_clause*, and the *LOB_storage_clause*.
- You cannot move a table containing a LONG or LONG RAW column.
- You cannot MOVE an entire partitioned table (either heap- or index-organized). You must move individual partitions or subpartitions.

> **Note:**
>
> For any LOB columns you specify in a *move_table_clause*:
>
> - Oracle Database drops the old LOB data segment and corresponding index segment and creates new segments, even if you do not specify a new tablespace.
> - If the LOB index in *table* resided in a different tablespace from the LOB data, then Oracle Database collocates the LOB index in the same tablespace with the LOB data after the move.

> **See Also:**
>
> *move_table_partition* and *move_table_subpartition*

modify_to_partitioned

Use this clause to partition a nonpartitioned or partitioned table, including indexes, online or offline.

You can change a nonpartitioned or partitioned table into any type of partitioned or composite partitioned table with the following characteristics:

- All data in the original table is preserved.
- The data in the newly created partitions or subpartitions of the modified table is stored in the same tablespace as the original table, unless you specify otherwise in the *table_partitioning_clauses*.

- Local index partitions or subpartitions and lob partitions or subpartitions of the modified table will be co- located with the table partitions or subpartitions unless you specify otherwise in the *table_partitioning_clauses*.
- All triggers, constraints, and VPD policies defined on the original table are preserved.
- If table compression is defined on the original nonpartitioned table, then the partitioned table will use the same type of table compression.
- In case of modifying a partitioned table, the compression setting of the newly created partitions or subpartitions is derived from the default compression setting of the partitioned table prior to the modification unless all partitions or subpartitions shared the same compression method.

Each range, list, or hash partitioning or subpartitioning key column with a character data type, specified in the *modify_to_partitioned* clause must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

table_partitioning_clauses

Use this clause to specify the partitioning attributes for the table.

Each range, list, or hash partitioning or subpartitioning key column with a character data type, specified in the *modify_to_partitioned* clause must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

This clause has the same semantics here as it has for the CREATE TABLE statement. Refer to the CREATE TABLE *table_partitioning_clauses* for the full semantics of this clause.

NONPARTITIONED

Specify NONPARTITIONED to convert a partitioned table back to a nonpartitioned state.

ONLINE

Specify ONLINE to indicate that DML operations on the table will be allowed while changing to a partitioned table.

UPDATE INDEXES

Use this clause to specify how existing indexes on the table are converted into global partitioned indexes or local partitioned indexes.

- For *index*, specify the name of an existing index on the table.
- Specify the *local_partitioned_index* clause to convert *index* into a local partitioned index. This clause has the same semantics here as it has for the CREATE INDEX statement. Refer to the clause *local_partitioned_index* in the documentation on CREATE INDEX for the full semantics of this clause.
- Specify the *global_partitioned_index* clause to convert *index* into a global partitioned index. This clause has the same semantics here as it has for the CREATE INDEX statement. Refer to the clause *global_partitioned_index* in the documentation on CREATE INDEX for the full semantics of this clause.
- Specify the GLOBAL keyword to allow prefixed partitioned and nonpartitioned global indexes to retain their global shape. This clause prevents such indexes from being converted to local partitioned indexes; it has no effect on nonprefixed global indexes.

If you specify only the UPDATE INDEXES keywords, or omit the UPDATE INDEXES clause altogether, then existing indexes are converted as follows:

- Nonprefixed indexes retain their original shape: normal indexes are converted to nonpartitioned global indexes, nonpartitioned global indexes remain the same, and partitioned global indexes remain the same and retain their partitioning shape.
- Prefixed indexes are converted to local partitioned indexes. Prefixed indexes include partitioning keys in the index definition, but the index definition is not limited to including only the partitioning keys.
- Bitmap indexes are converted to local partitioned indexes, regardless of whether they are prefixed or not.

Default Index Rules for Conversion from Partitioned to Partitioned Table

The rule set for default index conversion for partitioned to partitioned table is identical to the one for nonpartitioned to partitioned table, with additional handling of existing local indexes on the partitioned table.

- If the index is already local, then the index stays as a local index if the index column is prefixed on both sides of the partitioning dimensions.
- If the partitioning columns are a subset of the key columns, (that is, they are prefixed), then the global index is converted to local. If the global index is not prefixed, then the shape of the global index is retained.

Restrictions on Changing a Nonpartitioned Table to a Partitioned Table

The following restrictions apply to the *modify_to_partitioned* clause:

- You cannot specify this clause for an index-organized table.
- You cannot specify this clause if a domain index is defined on the table.
- You cannot specify `ONLINE` when changing a nonpartitioned table to a reference-partitioned child table. This operation is supported only in offline mode.

> **See Also:**
>
> *Oracle Database VLDB and Partitioning Guide* for more information on converting a nonpartitioned table into a partitioned table

modify_opaque_type

Use the *modify_opaque_type* clause to instruct the database to store the specified abstract data type or `XMLType` in an `ANYDATA` column using unpacked storage.

You can specify any abstract data type with this clause. However, it is primarily useful because it allows you to specify the following data types, which cannot be stored in an `ANYDATA` column using conventional storage:

- `XMLType`
- Abstract data types that contain one or more attributes of type `XMLType`, `CLOB`, `BLOB`, or `NCLOB`.

When you use **unpacked storage**, data types are stored in system-generated hidden columns that are associated with the `ANYDATA` column. You can insert and query these data types as you would data types that are stored in an `ANYDATA` column using conventional storage.

anydata_column

Specify the name of a column of type ANYDATA. If *type_name* is an abstract data type that does not contain an attribute of type XMLType, CLOB, BLOB, or NCLOB, then *anydata_column* must be empty.

type_name

Specify the name of one or more abstract data types or XMLType. The abstract data type can contain an attribute of type XMLType, CLOB, BLOB, or NCLOB. The type can be EDITIONABLE. When you subsequently insert these data types into *anydata_column*, they will use unpacked storage. If you previously specified this clause for the same *anydata_column*, then unpacked storage will continue to be used for the previously specified data types as well as the newly specified data types.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for information on the ANYDATA type and "Unpacked Storage in ANYDATA Columns: Example"

immutable_table_clauses

You can use the NO DROP or NO DELETE clauses to modify the definition of an immutable table.

Use the NO DROP clause to modify the retention period for an immutable table or the retention period for rows within the immutable table. You cannot reduce the retention period.

Example : Modifying the Retention Period for an Immutable Table

The following statement modifies the definition of the immutable table *imm_tab* and specifies that it cannot be dropped if the newest row is less than 50 days old.

```
ALTER TABLE imm_tab NO DROP UNTIL 50 DAYS IDLE;
```

Example : Modifying the Retention Period for Immutable Table Rows

The following statement modifies the definition of the immutable table *imm_tab* and specifies that rows cannot be deleted until 120 days after they were created.

```
ALTER TABLE imm_tab NO DELETE UNTIL 120 DAYS AFTER
    INSERT;
```

blockchain_table_clauses

You can modify a table created using the keyword BLOCKCHAIN in the ALTER TABLE statement, and one or more of the *blockchain_table_clauses*.

See *blockchain_table_clauses* of CREATE TABLE for the full semantics of the clause.

You can add, drop, and rename a column in a V2 blockchain table.

Use the *blockchain_system_chains_clause* to configure the number of system chains in a blockchain table. The range of permissible values is 1 to 1024. For ALTER TABLE, you can increase or decrease the number of system chains per instance, but you cannot configure a number of system chains per instance that is less than the maximum number of a system chain already in the blockchain table.

You cannot use the *blockchain_hash_and_data_format_clause* of the *blockchain_table_clauses* in the ALTER TABLE statement.

Restrictions on All Versions of Blockchain Tables V1 and V2

You can use all the clauses of `ALTER TABLE` on a blockchain table except the following clauses:

- `DROP (SUB)PARTITION`
- `TRUNCATE (SUB)PARTITION`
- `EXCHANGE (SUB)PARTITION`
- `MODIFY TYPE`
- `RENAME TABLE`

Additional Restrictions on V1 Blockchain Tables

The following `ADD`, `DROP`, and `RENAME COLUMN` restrictions apply to V1 blockchain tables but not V2 blockchain tables:

- `RENAME COLUMN`
- `ADD COLUMN`
- `DROP COLUMN`

duplicated_table_refresh

Use this clause to specify fine-grained refresh rate control for a duplicated table when it is created with `CREATE TABLE`. You can also specify the refresh rate later with `ALTER TABLE`.

enable_disable_clause

The *`enable_disable_clause`* lets you specify whether and how Oracle Database should apply an integrity constraint. The `DROP` and `KEEP` clauses are valid only when you are disabling a unique or primary key constraint.

> **See Also:**
>
> The *enable_disable_clause* (in `CREATE TABLE`) for a complete description of this clause, including notes and restrictions that relate to this statement

TABLE LOCK

Oracle Database permits DDL operations on a table only if the table can be locked during the operation. Such table locks are not required during DML operations.

> **Note:**
>
> Table locks are not acquired on temporary tables.

- Specify `ENABLE TABLE LOCK` to enable table locks, thereby allowing DDL operations on the table. All currently executing transactions must commit or roll back before Oracle Database enables the table lock.

> **Note:**
>
> Oracle Database waits until active DML transactions in the database have completed before locking the table. Sometimes the resulting delay is considerable.

- Specify `DISABLE TABLE LOCK` to disable table locks, thereby preventing DDL operations on the table.

> **Note:**
>
> Parallel DML operations are not performed when the table lock of the target table is disabled.

ALL TRIGGERS

Use the `ALL TRIGGERS` clause to enable or disable all triggers associated with the table.

- Specify `ENABLE ALL TRIGGERS` to enable all triggers associated with the table. Oracle Database fires the triggers whenever their triggering condition is satisfied.

  To enable a single trigger, use the *`enable_clause`* of `ALTER TRIGGER`.

> **See Also:**
>
> CREATE TRIGGER , ALTER TRIGGER , and "Enabling Triggers: Example"

- Specify `DISABLE ALL TRIGGERS` to disable all triggers associated with the table. Oracle Database does not fire a disabled trigger even if the triggering condition is satisfied.

CONTAINER_MAP

Use the `CONTAINER_MAP` clause to enable or disable the table to be queried using a container map.

- Specify `ENABLE CONTAINER_MAP` to enable the table to be queried using a container map.
- Specify `DISABLE CONTAINER_MAP` to disable the table from being queried using a container map.

CONTAINERS_DEFAULT

Use the `CONTAINERS_DEFAULT` clause to enable or disable the table for the `CONTAINERS` clause.

- Specify `ENABLE CONTAINERS_DEFAULT` to enable the table for the `CONTAINERS` clause.
- Specify `DISABLE CONTAINERS_DEFAULT` to disable the table for the `CONTAINERS` clause.

Examples

Adding Constraints to Tables: Example

The following statements create a new table to manipulate data and display the information in the newly created table:

```
CREATE TABLE JOBS_Temp AS SELECT * FROM HR.JOBS;

SELECT * FROM JOBS_Temp WHERE MIN_SALARY < 3000;

JOB_ID       JOB_TITLE                     MIN_SALARY MAX_SALARY
---------- ---------------------------------- ---------- ----------
PU_CLERK   Purchasing Clerk                 2500    5500
ST_CLERK   Stock Clerk                      2008    5000
SH_CLERK   Shipping Clerk                   2500    5500
```

The following statement updates the column values to a higher value:

```
UPDATE JOBS_Temp SET MIN_SALARY = 2300 WHERE MIN_SALARY < 2010;
```

The following statement adds a constraint:

```
ALTER TABLE JOBS_Temp ADD CONSTRAINT chk_sal_min CHECK (MIN_SALARY >=2010);
```

The following statement displays the table information:

```
SELECT * FROM JOBS_Temp WHERE MIN_SALARY < 3000;

JOB_ID       JOB_TITLE                     MIN_SALARY MAX_SALARY
---------- ---------------------------------- ---------- ----------
PU_CLERK   Purchasing Clerk                 2500    5500
ST_CLERK   Stock Clerk                      2300    5000
SH_CLERK   Shipping Clerk                   2500    5500
```

The following statement displays the constraint:

```
SELECT CONSTRAINT_NAME FROM USER_CONSTRAINTS WHERE TABLE_NAME='JOBS_TEMP';

CONSTRAINT_NAME
--------------------------------------------------------------------------------
SYS_C008830
CHK_SAL_MIN
```

Adding and Modifying Precheck State Constraint: Example

The following statement create a product table with constraint state `PRECHECK` set on some columns:

```
CREATE TABLE product(
  id NUMBER NOT NULL PRIMARY KEY,
  name VARCHAR2(50),
  price NUMBER CHECK (mod(price,4) = 0 and 10 <> price) PRECHECK,
  color NUMBER CHECK (color >= 10 and color <=50 and mod(color,2) = 0)
    PRECHECK,
  description VARCHAR2(50) CHECK (length(description) <= 40) PRECHECK,
  constant NUMBER CHECK (constant=10) PRECHECK,
  CONSTRAINT TC1 CHECK (color > 0 AND price > 10) PRECHECK,
  CONSTRAINT TC2 CHECK (CATEGORY IN ('home', 'apparel') AND price > 10)
);
```

Add precheck to a new constraint

```
ALTER TABLE product MODIFY (name VARCHAR2(50) CHECK
  (regexp_like(name, '^Product')) PRECHECK);
```

Modify an existing constraint `TC2`:

```
ALTER TABLE product MODIFY CONSTRAINT TC2 PRECHECK;
```

Remove an exisiting precheck constraint on `TC1`:

```
ALTER TABLE product MODIFY CONSTRAINT TC1 NOPRECHECK;
```

Collection Retrieval: Example

The following statement modifies nested table column `ad_textdocs_ntab` in the sample table `sh.print_media` so that when queried it returns actual values instead of locators:

```
ALTER TABLE print_media MODIFY NESTED TABLE ad_textdocs_ntab
   RETURN AS VALUE;
```

Specifying Parallel Processing: Example

The following statement specifies parallel processing for queries to the sample table `oe.customers`:

```
ALTER TABLE customers
   PARALLEL;
```

Changing the State of a Constraint: Examples

The following statement places in `ENABLE VALIDATE` state an integrity constraint named `emp_manager_fk` in the `employees` table:

```
ALTER TABLE employees
   ENABLE VALIDATE CONSTRAINT emp_manager_fk
   EXCEPTIONS INTO exceptions;
```

Each row of the `employees` table must satisfy the constraint for Oracle Database to enable the constraint. If any row violates the constraint, then the constraint remains disabled. The database lists any exceptions in the table `exceptions`. You can also identify the exceptions in the `employees` table with the following statement:

```
SELECT e.*
   FROM employees e, exceptions ex
   WHERE e.rowid = ex.row_id
      AND ex.table_name = 'EMPLOYEES'
      AND ex.constraint = 'EMP_MANAGER_FK';
```

The following statement tries to place in `ENABLE NOVALIDATE` state two constraints on the `employees` table:

```
ALTER TABLE employees
   ENABLE NOVALIDATE PRIMARY KEY
   ENABLE NOVALIDATE CONSTRAINT emp_last_name_nn;
```

This statement has two `ENABLE` clauses:

- The first places a primary key constraint on the table in `ENABLE NOVALIDATE` state.
- The second places the constraint named `emp_last_name_nn` in `ENABLE NOVALIDATE` state.

In this case, Oracle Database enables the constraints only if both are satisfied by each row in the table. If any row violates either constraint, then the database returns an error and both constraints remain disabled.

Consider the foreign key constraint on the `location_id` column of the `departments` table, which references the primary key of the `locations` table. The following statement disables the primary key of the `locations` table:

```
ALTER TABLE locations
   MODIFY PRIMARY KEY DISABLE CASCADE;
```

The unique key in the `locations` table is referenced by the foreign key in the `departments` table, so you must specify `CASCADE` to disable the primary key. This clause disables the foreign key as well.

Creating an Exceptions Table for Index-Organized Tables: Example

The following example creates the `except_table` table to hold rows from the index-organized table `hr.countries` that violate the primary key constraint:

```
EXECUTE DBMS_IOT.BUILD_EXCEPTIONS_TABLE ('hr', 'countries', 'except_table');

ALTER TABLE countries
   ENABLE PRIMARY KEY
   EXCEPTIONS INTO except_table;
```

To specify an exception table, you must have the privileges necessary to insert rows into the table. To examine the identified exceptions, you must have the privileges necessary to query the exceptions table.

> **See Also:**
>
> INSERT and SELECT for information on the privileges necessary to insert rows into tables

Disabling a CHECK Constraint: Example

The following statement defines and disables a `CHECK` constraint on the `employees` table:

```
ALTER TABLE employees ADD CONSTRAINT check_comp
   CHECK (salary + (commission_pct*salary) <= 5000)
   DISABLE;
```

The constraint `check_comp` ensures that no employee's total compensation exceeds $5000. The constraint is disabled, so you can increase an employee's compensation above this limit.

Enabling Triggers: Example

The following statement enables all triggers associated with the `employees` table:

```
ALTER TABLE employees
   ENABLE ALL TRIGGERS;
```

Deallocating Unused Space: Example

The following statement frees all unused space for reuse in table `employees`, where the high water mark is above `MINEXTENTS`:

```
ALTER TABLE employees
    DEALLOCATE UNUSED;
```

Modifying the Collation of a Column for Fine-Grained Case-Insensitivity: Example

This example shows how to modify a column to be case-insensitive. First, create and populate table `students` as follows:

```
CREATE TABLE students (last_name VARCHAR2(20), id NUMBER);

INSERT INTO students VALUES('Dodd', 364);
INSERT INTO students VALUES('de Niro', 132);
INSERT INTO students VALUES('Vogel', 837);
INSERT INTO students VALUES('van der Kamp', 549);
INSERT INTO students VALUES('van Der Meer', 624);
```

The following statement returns column `last_name` in alphabetical order. Notice that the results are case-sensitive; lowercase letters are ordered after uppercase letters.

```
SELECT last_name, id
  FROM students
  ORDER BY last_name;

LAST_NAME                    ID
-------------------- ----------
Dodd                        364
Vogel                       837
de Niro                     132
van Der Meer                624
van der Kamp                549
```

The following statement changes the data-bound collation of column `last_name` to case-insensitive collation `BINARY_CI`:

```
ALTER TABLE students
  MODIFY (last_name COLLATE BINARY_CI);
```

The following statement again returns column `last_name` in alphabetical order. Notice that the results are now case-insensitive:

```
SELECT last_name, id
  FROM students
  ORDER BY last_name;

LAST_NAME                    ID
-------------------- ----------
de Niro                     132
Dodd                        364
van der Kamp                549
van Der Meer                624
Vogel                       837
```

Renaming a Column: Example

The following example renames the `credit_limit` column of the sample table `oe.customers` to `credit_amount`:

```
ALTER TABLE customers
   RENAME COLUMN credit_limit TO credit_amount;
```

Dropping a Column: Example

This statement illustrates the *`drop_column_clause`* with `CASCADE CONSTRAINTS`. Assume table `t1` is created as follows:

```
CREATE TABLE t1 (
   pk NUMBER PRIMARY KEY,
   fk NUMBER,
   c1 NUMBER,
   c2 NUMBER,
```

```
   CONSTRAINT ri FOREIGN KEY (fk) REFERENCES t1,
   CONSTRAINT ck1 CHECK (pk > 0 and c1 > 0),
   CONSTRAINT ck2 CHECK (c2 > 0)
);
```

An error will be returned for the following statements:

```
ALTER TABLE t1 DROP (pk);  -- pk is a parent key
ALTER TABLE t1 DROP (c1);  -- c1 is referenced by multicolumn
                           -- constraint ck1
```

Submitting the following statement drops column `pk`, the primary key constraint, the foreign key constraint, `ri`, and the check constraint, `ck1`:

```
ALTER TABLE t1 DROP (pk) CASCADE CONSTRAINTS;
```

If all columns referenced by the constraints defined on the dropped columns are also dropped, then `CASCADE CONSTRAINTS` is not required. For example, assuming that no other referential constraints from other tables refer to column `pk`, then it is valid to submit the following statement without the `CASCADE CONSTRAINTS` clause:

```
ALTER TABLE t1 DROP (pk, fk, c1);
```

Dropping Unused Columns: Example

The following statements create a new table to manipulate data and display the information in the newly created table:

```
CREATE TABLE JOBS_Temp AS SELECT * FROM HR.JOBS;

SELECT * FROM JOBS_Temp WHERE MAX_SALARY > 20000;

JOB_ID       JOB_TITLE                    MIN_SALARY MAX_SALARY
---------- ---------------------------------- ---------- ----------
AD_PRES    President                     20080      40000
AD_VP       Administration Vice President        15000      30000
SA_MAN       Sales Manager                10000      20080
```

The following statement adds two new columns:

```
ALTER TABLE JOBS_Temp ADD (DUMMY1 NUMBER(2), DUMMY2 NUMBER(2));
```

The following statements inserts values into the newly added columns:

```
INSERT INTO JOBS_Temp(JOB_ID, JOB_TITLE, DUMMY1, DUMMY2) VALUES ('D','DUMMY',10,20);

INSERT INTO JOBS_Temp(JOB_ID, JOB_TITLE, DUMMY1, DUMMY2) VALUES ('D','DUMMY',10,20)
```

The following statement sets the newly added columns to unused:

```
ALTER TABLE JOBS_TEMP SET UNUSED (DUMMY1, DUMMY2);
```

The following statement displays the count of unused columns:

```
SELECT * FROM USER_UNUSED_COL_TABS WHERE TABLE_NAME='JOBS_TEMP';

TABLE_NAM      COUNT
--------- ----------
JOBS_TEMP       2
```

The following statement drops the unused columns:

```
ALTER TABLE JOBS_TEMP DROP UNUSED COLUMNS;
```

The following statement displays the table information:

```
SELECT * FROM JOBS_TEMP;

JOB_ID       JOB_TITLE                     MIN_SALARY MAX_SALARY
---------- ---------------------------------- ---------- ----------
AD_PRES    President                     20080      40000
AD_VP       Administration Vice President        15000      30000
AD_ASST    Administration Assistant              3000    6000
FI_MGR       Finance Manager                  8200      16000
FI_ACCOUNT Accountant                      4200    9000
AC_MGR       Accounting Manager                 8200      16000

```

Modifying Index-Organized Tables: Examples

This statement modifies the `INITRANS` parameter for the index segment of index-organized table `countries_demo`, which is based on `hr.countries`:

```
ALTER TABLE countries_demo INITRANS 4;
```

The following statement adds an overflow data segment to index-organized table `countries`:

```
ALTER TABLE countries_demo ADD OVERFLOW;
```

This statement modifies the `INITRANS` parameter for the overflow data segment of index-organized table `countries`:

```
ALTER TABLE countries_demo OVERFLOW INITRANS 4;
```

Splitting Table Partitions: Examples

The following statement splits the old partition `sales_q4_2000` in the sample table `sh.sales`, creating two new partitions, naming one `sales_q4_2000b` and reusing the name of the old partition for the other:

```
ALTER TABLE sales SPLIT PARTITION SALES_Q4_2000
   AT (TO_DATE('15-NOV-2000','DD-MON-YYYY'))
   INTO (PARTITION SALES_Q4_2000, PARTITION SALES_Q4_2000b);
```

The following statement splits the old partition `sales_q1_2002` into three new partitions `sales_jan_2002`, `sales_feb_2002`, and `sales_mar_2002`:

```
ALTER TABLE sales SPLIT PARTITION SALES_Q1_2002 INTO (
 PARTITION SALES_JAN_2002 VALUES LESS THAN (TO_DATE('01-FEB-2002','DD-MON-YYYY')),
```

```
 PARTITION SALES_FEB_2002 VALUES LESS THAN (TO_DATE('01-MAR-2002','DD-MON-YYYY')),
 PARTITION SALES_MAR_2002);
```

The following statements create a partitioned version of the pm.print_media table. The `LONG` column in the print_media table has been converted to LOB. The table is stored in tablespaces created in "Creating Oracle Managed Files: Examples". The object types underlying the `ad_textdocs_ntab` and `ad_header` columns are created in the script that creates the `pm` sample schema:

```
CREATE TABLE print_media_part (
    product_id NUMBER(6),
    ad_id              NUMBER(6),
    ad_composite       BLOB,
    ad_sourcetext      CLOB,
    ad_finaltext       CLOB,
    ad_fltextn         NCLOB,
    ad_textdocs_ntab   TEXTDOC_TAB,
    ad_photo           BLOB,
    ad_graphic         BFILE,
    ad_header          ADHEADER_TYP)
  NESTED TABLE ad_textdocs_ntab STORE AS textdoc_nt
  PARTITION BY RANGE (product_id)
    (PARTITION p1 VALUES LESS THAN (100),
     PARTITION p2 VALUES LESS THAN (200));
```

The following statement splits partition `p2` of that table into partitions `p2a` and `p2b`:

```
ALTER TABLE print_media_part
   SPLIT PARTITION p2 AT (150) INTO
   (PARTITION p2a TABLESPACE omf_ts1
      LOB (ad_photo, ad_composite) STORE AS (TABLESPACE omf_ts2),
   PARTITION p2b
      LOB (ad_photo, ad_composite) STORE AS (TABLESPACE omf_ts2))
   NESTED TABLE ad_textdocs_ntab INTO (PARTITION nt_p2a, PARTITION nt_p2b);
```

In both partitions `p2a` and `p2b`, Oracle Database creates the LOB segments for columns `ad_photo` and `ad_composite` in tablespace `omf_ts2`. The LOB segments for the remaining columns in partition p2a are stored in tablespace omf_ts1. The LOB segments for the remaining columns in partition p2b remain in the tablespaces in which they resided prior to this `ALTER` statement. However, the database creates new segments for all the LOB data and LOB index segments, even if they are not moved to a new tablespace.

The database also creates new segments for nested table column `ad_textdocs_ntab`. The storage tables is those new segments are `nt_p2a` and `nt_p2b`.

Merging Two Table Partitions: Example

The following statement merges back into one partition the partitions created in "Splitting Table Partitions: Examples":

```
ALTER TABLE sales
   MERGE PARTITIONS sales_q4_2000, sales_q4_2000b
   INTO PARTITION sales_q4_2000;
```

The next statement reverses the example in "Splitting Table Partitions: Examples":

```
ALTER TABLE print_media_part
   MERGE PARTITIONS p2a, p2b INTO PARTITION p2ab TABLESPACE example
   NESTED TABLE ad_textdocs_ntab STORE AS nt_p2ab;
```

Merging Four Adjacent Range Partitions: Example

The following statement merges four adjacent range partitions, `sales_q1_2000`, `sales_q2_2000`, `sales_q3_2000`, and `sales_q4_2000` into one partition `sales_all_2000`:

```
ALTER TABLE sales
  MERGE PARTITIONS sales_q1_2000 TO sales_q4_2000
  INTO PARTITION sales_all_2000;
```

Adding a Table Partition with a LOB and Nested Table Storage: Examples

The following statement adds a partition `p3` to the `print_media_part` table (see preceding example) and specifies storage characteristics for the `BLOB`, `CLOB`, and nested table columns of that table:

```
ALTER TABLE print_media_part ADD PARTITION p3 VALUES LESS THAN (400)
  LOB(ad_photo, ad_composite) STORE AS (TABLESPACE omf_ts1)
  LOB(ad_sourcetext, ad_finaltext) STORE AS (TABLESPACE omf_ts2)
  NESTED TABLE ad_textdocs_ntab STORE AS nt_p3;
```

The LOB data and LOB index segments for columns `ad_photo` and `ad_composite` in partition `p3` will reside in tablespace `omf_ts1`. The remaining attributes for these LOB columns will be inherited first from the table-level defaults, and then from the tablespace defaults.

The LOB data segments for columns `ad_source_text` and `ad_finaltext` will reside in the `omf_ts2` tablespace, and will inherit all other attributes first from the table-level defaults, and then from the tablespace defaults.

The partition for the storage table for nested table storage column `ad_textdocs_ntab` corresponding to partition `p3` of the base table is named `nt_p3` and inherits all other attributes first from the table-level defaults, and then from the tablespace defaults.

Adding Multiple Partitions to a Table: Example

The following statement adds three partitions to the table `print_media_part` created in "Splitting Table Partitions: Examples":

```
ALTER TABLE print_media_part ADD
  PARTITION p3 values less than (300),
  PARTITION p4 values less than (400),
  PARTITION p5 values less than (500);
```

Working with Default List Partitions: Example

The following statements use the list partitioned table created in "List Partitioning Example". The first statement splits the existing default partition into a new `south` partition and a default partition:

```
ALTER TABLE list_customers SPLIT PARTITION rest
   VALUES ('MEXICO', 'COLOMBIA')
   INTO (PARTITION south, PARTITION rest);
```

The next statement merges the resulting default partition with the `asia` partition:

```
ALTER TABLE list_customers
   MERGE PARTITIONS asia, rest INTO PARTITION rest;
```

The next statement re-creates the `asia` partition by splitting the default partition:

```
ALTER TABLE list_customers SPLIT PARTITION rest
   VALUES ('CHINA', 'THAILAND')
   INTO (PARTITION asia, PARTITION rest);
```

Dropping a Table Partition: Example

The following statement drops partition p3 created in "Adding a Table Partition with a LOB and Nested Table Storage: Examples":

```
ALTER TABLE print_media_part DROP PARTITION p3;
```

Exchanging Table Partitions: Example

This example creates the table exchange_table with the same structure as the partitions of the list_customers table created in "List Partitioning Example". It then replaces partition rest of table list_customers with table exchange_table without exchanging local index partitions with corresponding indexes on exchange_table and without verifying that data in exchange_table falls within the bounds of partition rest:

```
CREATE TABLE exchange_table (
   customer_id     NUMBER(6),
   cust_first_name VARCHAR2(20),
   cust_last_name  VARCHAR2(20),
   cust_address    CUST_ADDRESS_TYP,
   nls_territory   VARCHAR2(30),
   cust_email      VARCHAR2(40));

ALTER TABLE list_customers
   EXCHANGE PARTITION rest WITH TABLE exchange_table
   WITHOUT VALIDATION;
```

Modifying Table Partitions: Examples

The following statement marks all the local index partitions corresponding to the asia partition of the list_customers table UNUSABLE:

```
ALTER TABLE list_customers MODIFY PARTITION asia
   UNUSABLE LOCAL INDEXES;
```

The following statement rebuilds all the local index partitions that were marked UNUSABLE:

```
ALTER TABLE list_customers MODIFY PARTITION asia
   REBUILD UNUSABLE LOCAL INDEXES;
```

Moving Table Partitions: Example

The following statement moves partition p2b (from "Splitting Table Partitions: Examples") to tablespace omf_ts1:

```
ALTER TABLE print_media_part
   MOVE PARTITION p2b TABLESPACE omf_ts1;
```

Renaming Table Partitions: Examples

The following statement renames a partition of the sh.sales table:

```
ALTER TABLE sales RENAME PARTITION sales_q4_2003 TO sales_currentq;
```

Truncating Table Partitions: Example

The following statement uses the print_media_demo table created in "Partitioned Table with LOB Columns Example". It deletes all the data in the p1 partition and deallocates the freed space:

```
ALTER TABLE print_media_demo
   TRUNCATE PARTITION p1 DROP STORAGE;
```

Updating Global Indexes: Example

The following statement splits partition `sales_q1_2000` of the sample table `sh.sales` and updates any global indexes defined on it:

```
ALTER TABLE sales SPLIT PARTITION sales_q1_2000
   AT (TO_DATE('16-FEB-2000','DD-MON-YYYY'))
   INTO (PARTITION q1a_2000, PARTITION q1b_2000)
   UPDATE GLOBAL INDEXES;
```

Updating Partitioned Indexes: Example

The following statement splits partition `costs_Q4_2003` of the sample table `sh.costs` and updates the local index defined on it. It uses the tablespaces created in "Creating Basic Tablespaces: Examples".

```
CREATE INDEX cost_ix ON costs(channel_id) LOCAL;

ALTER TABLE costs
  SPLIT PARTITION costs_q4_2003 at
    (TO_DATE('01-Nov-2003','dd-mon-yyyy'))
    INTO (PARTITION c_p1, PARTITION c_p2)
  UPDATE INDEXES (cost_ix (PARTITION c_p1 tablespace tbs_02,
                           PARTITION c_p2 tablespace tbs_03));
```

Specifying Object Identifiers: Example

The following statements create an object type, a corresponding object table with a primary-key-based object identifier, and a table having a user-defined `REF` column:

```
CREATE TYPE emp_t AS OBJECT (empno NUMBER, address CHAR(30));

CREATE TABLE emp OF emp_t (
   empno PRIMARY KEY)
   OBJECT IDENTIFIER IS PRIMARY KEY;

CREATE TABLE dept (dno NUMBER, mgr_ref REF emp_t SCOPE is emp);
```

The next statements add a constraint and a user-defined `REF` column, both of which reference table `emp`

```
ALTER TABLE dept ADD CONSTRAINT mgr_cons FOREIGN KEY (mgr_ref)
   REFERENCES emp;
ALTER TABLE dept ADD sr_mgr REF emp_t REFERENCES emp;
```

Adding a Table Column: Example

The following statement adds to the `countries` table a column named `duty_pct` of data type `NUMBER` and a column named `visa_needed` of data type `VARCHAR2` with a size of 3 and a `CHECK` integrity constraint:

```
ALTER TABLE countries
   ADD (duty_pct     NUMBER(2,2)  CHECK (duty_pct < 10.5),
        visa_needed  VARCHAR2(3));
```

Adding a Virtual Table Column: Example

The following statement adds to a copy of the `hr.employees` table a column named `income`, which is a combination of salary plus commission. Both salary and commission are `NUMBER` columns, so the database creates the virtual column as a `NUMBER` column even though the data type is not specified in the statement:

```
CREATE TABLE emp2 AS SELECT * FROM employees;

ALTER TABLE emp2 ADD (income AS (salary + (salary*commission_pct)));
```

Modifying Table Columns: Examples

The following statement increases the size of the `duty_pct` column:

```
ALTER TABLE countries
   MODIFY (duty_pct NUMBER(3,2));
```

Because the `MODIFY` clause contains only one column definition, the parentheses around the definition are optional.

The following statement changes the values of the `PCTFREE` and `PCTUSED` parameters for the `employees` table to 30 and 60, respectively:

```
ALTER TABLE employees
   PCTFREE 30
   PCTUSED 60;
```

Modifying Storage Attributes for a Table

The following statement creates a table named `JOBS_TEMP` by using the existing `JOBS` table:

```
CREATE TABLE JOBS_TEMP AS SELECT * FROM HR.JOBS;
```

The following statement queries the `USER_TABLES` table for storage parameters:

```
SELECT initial_extent,
       next_extent,
       min_extents,
       max_extents,
       pct_increase,
       blocks,
       sample_size
FROM   user_tables
WHERE  table_name = 'JOBS_TEMP';

INITIAL_EXTENT NEXT_EXTENT MIN_EXTENTS MAX_EXTENTS PCT_INCREASE     BLOCKS
SAMPLE_SIZE
-------------- ----------- ----------- ----------- ------------ ----------
-----------
         65536     1048576           1  2147483645
1          19
```

The following statement alters the `JOBS_TEMP` table with new storage parameters:

```
ALTER TABLE JOBS_TEMP MOVE
      STORAGE ( INITIAL 20K
                NEXT 40K
                MINEXTENTS 2
                MAXEXTENTS 20
                PCTINCREASE 0 )
      TABLESPACE USERS;
```

The following statement queries the `USER_TABLES` table for the new storage parameters:

```
SELECT initial_extent,
       next_extent,
       min_extents,
       max_extents,
       pct_increase,
       blocks,
       sample_size
FROM   user_tables
WHERE  table_name = 'JOBS_TEMP';

INITIAL_EXTENT NEXT_EXTENT MIN_EXTENTS MAX_EXTENTS PCT_INCREASE     BLOCKS
SAMPLE_SIZE
-------------- ----------- ----------- ----------- ------------ ----------
-----------
         65536       40960           1  2147483645
1          19
```

Adding, Altering, Renaming and Dropping Table Columns: Example

The following statements create a new table to manipulate data and display the information in the newly created table:

```
CREATE TABLE JOBS_Temp AS SELECT * FROM HR.JOBS;

SELECT * FROM JOBS_Temp WHERE MAX_SALARY > 30000;

JOB_ID       JOB_TITLE                    MIN_SALARY MAX_SALARY
---------- ---------------------------------- ---------- ----------
AD_PRES    President                    20080      40000
```

The following statement modifies an existing column definition:

```
ALTER TABLE JOBS_Temp MODIFY(JOB_TITLE VARCHAR2(100));
```

The following statement adds two new columns to the table:

```
ALTER TABLE JOBS_Temp ADD (BONUS NUMBER (7,2), COMM NUMBER (5,2), DUMMY NUMBER(2));
```

The following statement displays the newly added columns:

```
SELECT JOB_ID, BONUS, COMM, DUMMY FROM JOBS_Temp WHERE MAX_SALARY > 20000;

JOB_ID        BONUS        COMM      DUMMY
---------- ---------- ---------- ----------
AD_PRES
AD_VP
SA_MAN
```

The following statements rename an existing column and display the modified column:

```
ALTER TABLE JOBS_Temp RENAME COLUMN COMM TO COMMISSION;

SELECT JOB_ID, COMMISSION FROM JOBS_Temp WHERE MAX_SALARY > 20000;

JOB_ID       COMMISSION
---------- ----------
AD_PRES
```

```
AD_VP
SA_MAN
```

The following statement drops a single column from the table:

```
ALTER TABLE JOBS_Temp DROP COLUMN DUMMY;
```

The following statement drops multiple columns from the table:

```
ALTER TABLE JOBS_Temp DROP (BONUS, COMMISSION);
```

Data Encryption: Examples

The following statement encrypts the salary column of the `hr.employees` table using the encryption algorithm `AES256`. As described in "Semantics" above, you must first enable Transparent Data Encryption:

```
ALTER TABLE employees
   MODIFY (salary ENCRYPT USING 'AES256' 'NOMAC');
```

The following statement adds a new encrypted column `online_acct_pw` to the `oe.customers` table, using the default encryption algorithm `AES192`. Specifying `NO SALT` will allow a B-tree index to be created on the column, if desired.

```
ALTER TABLE customers
   ADD (online_acct_pw VARCHAR2(8) ENCRYPT 'NOMAC' NO SALT);
```

The following example decrypts the customer.online_acct_pw column:

```
ALTER TABLE customers
   MODIFY (online_acct_pw DECRYPT);
```

Allocating Extents: Example

The following statement allocates an extent of 5 kilobytes for the `employees` table and makes it available to instance 4:

```
ALTER TABLE employees
  ALLOCATE EXTENT (SIZE 5K INSTANCE 4);
```

Because this statement omits the `DATAFILE` parameter, Oracle Database allocates the extent in one of the data files belonging to the tablespace containing the table.

Specifying a Default Column Value: Examples

This statement modifies the `min_price` column of the `product_information` table so that it has a default value of 10:

```
ALTER TABLE product_information
  MODIFY (min_price DEFAULT 10);
```

If you subsequently add a new row to the `product_information` table and do not specify a value for the `min_price` column, then the value of the `min_price` column is automatically 10:

```
INSERT INTO product_information (product_id, product_name,
   list_price)
   VALUES (300, 'left-handed mouse', 40.50);

SELECT product_id, product_name, list_price, min_price
    FROM product_information
    WHERE product_id = 300;

PRODUCT_ID PRODUCT_NAME         LIST_PRICE  MIN_PRICE
```

```
---------- -------------------- ---------- ----------
       300 left-handed mouse          40.5         10
```

To discontinue previously specified default values, so that they are no longer automatically inserted into newly added rows, replace the values with `NULL`, as shown in this statement:

```
ALTER TABLE product_information
   MODIFY (min_price DEFAULT NULL);
```

The `MODIFY` clause need only specify the column name and the modified part of the definition, rather than the entire column definition. This statement has no effect on any existing values in existing rows.

The following example adds a column defined with `DEFAULT ON NULL` to a table. The `DEFAULT` column value includes the sequence pseudocolumn `NEXTVAL`.

Create sequence `s1` and table `t1` as follows:

```
CREATE SEQUENCE s1 START WITH 1;

CREATE TABLE t1 (name VARCHAR2(10));
INSERT INTO t1 VALUES('Kevin');
INSERT INTO t1 VALUES('Julia');
INSERT INTO t1 VALUES('Ryan');
```

Add column `id`, which defaults to `s1.NEXTVAL`. The default column value for `id` is assigned to each existing row in the table. The order in which `s1.NEXTVAL` is assigned to each row is nondeterministic.

```
ALTER TABLE t1 ADD (id NUMBER DEFAULT ON NULL s1.NEXTVAL NOT NULL);

SELECT id, name FROM t1 ORDER BY id;

        ID NAME
---------- ----------
         1 Kevin
         2 Julia
         3 Ryan
```

If you subsequently add a new row to the table and specify a NULL value for the `id` column, then the `DEFAULT ON NULL` expression `s1.NEXTVAL` is inserted.

```
INSERT INTO t1(id, name) VALUES(NULL, 'Sean');

SELECT id, name FROM t1 ORDER BY id;

        ID NAME
---------- ----------
         1 Kevin
         2 Julia
         3 Ryan
         4 Sean
```

Adding a Constraint to an XMLType Table: Example

The following example adds a primary key constraint to the `xwarehouses` table, created in "XMLType Examples":

```
ALTER TABLE xwarehouses
   ADD (PRIMARY KEY(XMLDATA."WarehouseID"));
```

Refer to XMLDATA Pseudocolumn for information about this pseudocolumn.

Renaming Constraints: Example

The following statement renames the `cust_fname_nn` constraint on the sample table `oe.customers` to `cust_firstname_nn`:

```
ALTER TABLE customers RENAME CONSTRAINT cust_fname_nn
   TO cust_firstname_nn;
```

Dropping Constraints: Examples

The following statement drops the primary key of the `departments` table:

```
ALTER TABLE departments
    DROP PRIMARY KEY CASCADE;
```

If you know that the name of the `PRIMARY KEY` constraint is `pk_dept`, then you could also drop it with the following statement:

```
ALTER TABLE departments
    DROP CONSTRAINT pk_dept CASCADE;
```

The `CASCADE` clause causes Oracle Database to drop any foreign keys that reference the primary key.

The following statement drops the unique key on the `email` column of the `employees` table:

```
ALTER TABLE employees
    DROP UNIQUE (email);
```

The `DROP` clause in this statement omits the `CASCADE` clause. Because of this omission, Oracle Database does not drop the unique key if any foreign key references it.

LOB Columns: Examples

The following statement adds `CLOB` column `resume` to the `employee` table and specifies LOB storage characteristics for the new column:

```
ALTER TABLE employees ADD (resume CLOB)
  LOB (resume) STORE AS resume_seg (TABLESPACE example);
```

To modify the LOB column `resume` to use caching, enter the following statement:

```
ALTER TABLE employees MODIFY LOB (resume) (CACHE);
```

The following statement adds a SecureFiles `CLOB` column `resume` to the `employee` table and specifies LOB storage characteristics for the new column. SecureFiles LOBs must be stored in tablespaces with automatic segment-space management. Therefore, the LOB data in this example is stored in the `auto_seg_ts` tablespace, which was created in "Specifying Segment Space Management for a Tablespace: Example":

```
ALTER TABLE employees ADD (resume CLOB)
LOB (resume) STORE AS SECUREFILE resume_seg (TABLESPACE auto_seg_ts);
```

To modify the LOB column `resume` so that it does not use caching, enter the following statement:

```
ALTER TABLE employees MODIFY LOB (resume) (NOCACHE);
```

Nested Tables: Examples

The following statement adds the nested table column `skills` to the `employee` table:

```
ALTER TABLE employees ADD (skills skill_table_type)
    NESTED TABLE skills STORE AS nested_skill_table;
```

You can also modify nested table storage characteristics. Use the name of the storage table specified in the *nested_table_col_properties* to make the modification. You cannot query or perform DML statements on the storage table. Use the storage table only to modify the nested table column storage characteristics.

The following statement creates table `vet_service` with nested table column `client` and storage table `client_tab`. Nested table `client_tab` is modified to specify constraints:

```
CREATE TYPE pet_t AS OBJECT
   (pet_id NUMBER, pet_name VARCHAR2(10), pet_dob DATE);
/

CREATE TYPE pet AS TABLE OF pet_t;
/

CREATE TABLE vet_service (vet_name VARCHAR2(30),
                          client   pet)
  NESTED TABLE client STORE AS client_tab;

ALTER TABLE client_tab ADD UNIQUE (pet_id);
```

The following statement alters the storage table for a nested table of `REF` values to specify that the `REF` is scoped:

```
CREATE TYPE emp_t AS OBJECT (eno number, ename char(31));
CREATE TYPE emps_t AS TABLE OF REF emp_t;
CREATE TABLE emptab OF emp_t;
CREATE TABLE dept (dno NUMBER, employees emps_t)
   NESTED TABLE employees STORE AS deptemps;
ALTER TABLE deptemps ADD (SCOPE FOR (COLUMN_VALUE) IS emptab);
```

Similarly, to specify storing the `REF` with rowid:

```
ALTER TABLE deptemps ADD (REF(column_value) WITH ROWID);
```

In order to execute these `ALTER TABLE` statements successfully, the storage table `deptemps` must be empty. Also, because the nested table is defined as a table of scalar values (`REF` values), Oracle Database implicitly provides the column name `COLUMN_VALUE` for the storage table.

> **See Also:**
>
> - CREATE TABLE for more information about nested table storage
> - *Oracle Database Object-Relational Developer's Guide* for more information about nested tables

REF Columns: Examples

The following statement creates an object type `dept_t` and then creates table `staff`:

```
CREATE TYPE dept_t AS OBJECT
   (deptno NUMBER, dname VARCHAR2(20));
/
```

```
CREATE TABLE staff
   (name   VARCHAR2(100),
    salary NUMBER,
    dept   REF dept_t);
```

An object table `offices` is created as:

```
CREATE TABLE offices OF dept_t;
```

The `dept` column can store references to objects of `dept_t` stored in any table. If you would like to restrict the references to point only to objects stored in the `departments` table, then you could do so by adding a scope constraint on the `dept` column as follows:

```
ALTER TABLE staff
    ADD (SCOPE FOR (dept) IS offices);
```

The preceding `ALTER TABLE` statement will succeed only if the `staff` table is empty.

If you want the `REF` values in the `dept` column of `staff` to also store the rowids, then issue the following statement:

```
ALTER TABLE staff
   ADD (REF(dept) WITH ROWID);
```

Unpacked Storage in ANYDATA Columns: Example

This example creates a table with an `ANYDATA` column, stores opaque data types in the `ANYDATA` column using unpacked storage, and then queries the data types. This example assumes that you are connected to the database as user `hr`.

Create table `t1`, which contains a `NUMBER` column `n` and an `ANYDATA` column `x`:

```
CREATE TABLE t1 (n NUMBER, x ANYDATA);
```

Create an object type `clob_typ`, which contains a `CLOB` attribute:

```
CREATE OR REPLACE TYPE clob_typ AS OBJECT (c clob);
/
```

Enable unpacked storage of the opaque data types `XMLType` and `clob_typ` in `ANYDATA` column `x` of table `t1`:

```
ALTER TABLE t1 MODIFY OPAQUE TYPE x STORE (XMLType, clob_typ) UNPACKED;
```

Insert `XMLType` and `clob_typ` objects into table `t1`. These types will use unpacked storage:

```
INSERT INTO t1
  VALUES(1, anydata.convertobject(XMLType('<Test>This is test XML</Test>')));

INSERT INTO t1
  VALUES(2, anydata.convertobject(clob_typ(TO_CLOB('This is a test CLOB'))));
```

Query table `t1` to view the names of the types stored in `ANYDATA` column `x`:

```
SELECT t1.*, anydata.getTypeName(t1.x) typename FROM t1;

    N X()                  TYPENAME
----- -------------------- --------------------
    1 ANYDATA()            SYS.XMLTYPE
    2 ANYDATA()            HR.CLOB_TYP
```

Create functions that allow you to query the values stored in the `XMLType` and `clob_typ` data types:

```
CREATE FUNCTION get_xmltype (ad IN ANYDATA) RETURN VARCHAR2 AS
      rtn_val PLS_INTEGER;
      my_xmltype XMLType;
      string_val VARCHAR2(30);
   BEGIN
      rtn_val := ad.getObject(my_xmltype);
      string_val := my_xmltype.getstringval();
      return (string_val);
   END;
/

CREATE FUNCTION get_clob_typ (ad IN ANYDATA) RETURN VARCHAR2 AS
      rtn_val PLS_INTEGER;
      my_clob_typ clob_typ;
      string_val VARCHAR2(30);
   BEGIN
      rtn_val := ad.getObject(my_clob_typ);
      string_val := (my_clob_typ.c);
      return (string_val);
   END;
/
```

Query table `t1` to view the values stored in each data type in `ANYDATA` column `x`:

```
SELECT t1.*, anydata.getTypeName(t1.x) typename,
  CASE
    WHEN anydata.gettypename(t1.x) = 'SYS.XMLTYPE' THEN get_xmltype(t1.x)
    WHEN anydata.gettypename(t1.x) = 'HR.CLOB_TYP' THEN get_clob_typ(t1.x)
  END string_value
FROM t1;

    N X()                  TYPENAME             STRING_VALUE
----- -------------------- -------------------- ------------------------------
    1 ANYDATA()            SYS.XMLTYPE          <Test>This is test XML</Test>
    2 ANYDATA()            HR.CLOB_TYP          This is a test CLOB
```

Additional Examples

For examples of defining integrity constraints with the `ALTER TABLE` statement, see the *constraint*.

For examples of changing the storage parameters of a table, see the storage_clause.

Add and Drop Annotations at the Table Level

The following examples use `table1` :

```
CREATE TABLE table1 (T NUMBER) ANNOTATIONS(Operations 'Sort', Hidden);
```

The following example drops all annotations from `table1`:

```
ALTER TABLE table1 ANNOTATIONS(DROP Operations, DROP Hidden);
```

The following example adds a new annotation `Operations` with a JSON value:

```
ALTER TABLE table1 ANNOTATIONS(ADD Operations '["Sort", "Group"]');
```

Add and Drop Annotations at the Column Level

The following example adds a new `Identity` annotation for column `T` of `table1`:

```
ALTER TABLE table1 MODIFY T ANNOTATIONS(Identity 'ID');
```

The following example adds `Hidden`, and drops `Identity`:

```
ALTER TABLE table1 MODIFY T ANNOTATIONS(ADD Hidden, DROP Identity);
```

Operations on Directory-Based Partitioned Table

Example: Create Sharded Table and Partition by Directory

```
CREATE SHARDED TABLE departments
  ( department_id  NUMBER(6)
   , department_name VARCHAR2(30) CONSTRAINT dept_name_nn NOT NULL
   , manager_id    NUMBER(6)
   , location_id   NUMBER(4)
   , CONSTRAINT dept_id_pk PRIMARY KEY(department_id)
   )
   PARTITION BY DIRECTORY (department_id)
   (
    PARTITION p_1 TABLESPACE tbs1,
    PARTITION p_2 TABLESPACE tbs2
   );
```

The following two examples use the table `departments` above for operations add and split.

Add Partitions to a Table Partitioned by Directory

```
ALTER TABLE departments ADD
    PARTITION p_3 TABLESPACE tbs3,
    PARTITION p_4 TABLESPACE tbs4;
```

Split Partitions of a Table Partitioned by Directory

```
ALTER TABLE departments
  SPLIT PARTITION p_1 INTO
   (PARTITION p_1 TABLESPACE tbs1,
    PARTITION p_3 TABLESPACE tbs3)
    UPDATE INDEXES;
```

ALTER TABLESPACE

Purpose

Use the `ALTER TABLESPACE` statement to alter an existing tablespace or one or more of its data files or temp files.

You cannot use this statement to convert a dictionary-managed tablespace to a locally managed tablespace. For that purpose, use the `DBMS_SPACE_ADMIN` package, which is documented in *Oracle Database PL/SQL Packages and Types Reference*.

> **See Also:**
>
> *Oracle Database Administrator's Guide* and CREATE TABLESPACE for information on creating a tablespace

Prerequisites

To alter the SYSAUX tablespace, you must have the SYSDBA system privilege.

If you have the ALTER TABLESPACE system privilege, then you can perform any ALTER TABLESPACE operation. If you have the MANAGE TABLESPACE system privilege, then you can only perform the following operations:

- Take a tablespace online or offline
- Begin or end a backup
- Make a tablespace read only or read write
- Change the state of a tablespace to PERMANENT or TEMPORARY
- Set the default logging mode of a tablespace to LOGGING or NOLOGGING
- Put a tablespace in force logging mode or take it out of force logging mode
- Rename a tablespace or a tablespace data file
- Specify RETENTION GUARANTEE or RETENTION NOGUARANTEE for an undo tablespace
- Resize a data file for a tablespace
- Enable or disable autoextension of a data file for a tablespace
- Shrink the amount of space a temporary tablespace or a temp file is taking

Before you can make a tablespace read only, the following conditions must be met:

- The tablespace must be online.
- The tablespace must not contain any active rollback segments. For this reason, the SYSTEM tablespace can never be made read only, because it contains the SYSTEM rollback segment. Additionally, because the rollback segments of a read-only tablespace are not accessible, Oracle recommends that you drop the rollback segments before you make a tablespace read only.
- The tablespace must not be involved in an open backup, because the end of a backup updates the header file of all data files in the tablespace.

Performing this function in restricted mode may help you meet these restrictions, because only users with RESTRICTED SESSION system privilege can be logged on.

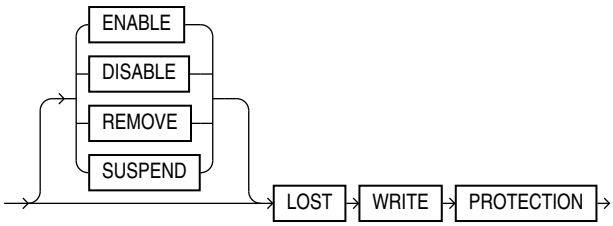
***lost_write_protection*::=**



Semantics

IF NOT EXISTS

Specify `IF EXISTS` to alter an existing tablespace.

Specifying `IF NOT EXISTS` with `ALTER` results in error: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

tablespace

Specify the name of the tablespace to be altered.

Restrictions on Altering Tablespaces

Altering tablespaces is subject to the following restrictions:

- If *tablespace* is an undo tablespace, then the only other clauses you can specify in this statement are ADD DATAFILE, RENAME DATAFILE, RENAME TO (renaming the tablespace), DATAFILE ... ONLINE, DATAFILE ... OFFLINE, BEGIN BACKUP, and END BACKUP.
- You cannot make the SYSTEM tablespace read only or temporary and you cannot take it offline.
- For locally managed temporary tablespaces, the only clause you can specify in this statement is the ADD clause.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information on automatic undo management and undo tablespaces

alter_tablespace_attrs

Use the *alter_tablespace_attrs* clauses to change the attributes of the tablespace.

default_tablespace_params

This clause lets you specify new default parameters for the tablespace. The new default parameters apply to objects subsequently created in the tablespace.

The clauses *default_table_compression*, *default_index_compression*, *inmemory_clause*, *ilm_clause*, and *storage_clause* have the same semantics in CREATE TABLESPACE and ALTER TABLESPACE. For complete information on these clauses, refer to the *default_tablespace_params* clause in the documentation on CREATE TABLESPACE.

MINIMUM EXTENT

This clause is valid only for permanent dictionary-managed tablespaces. The MINIMUM EXTENT clause lets you control free space fragmentation in the tablespace by ensuring that every used or free extent in a tablespace is at least as large as, and is a multiple of, the value specified in the *size_clause*.

Restriction on MINIMUM EXTENT

You cannot specify this clause for a locally managed tablespace or for a dictionary-managed temporary tablespace.

> **See Also:**
>
> *size_clause* for information about that clause, *Oracle Database Administrator's Guide* for more information about using MINIMUM EXTENT to control space fragmentation

RESIZE Clause

This clause is valid only for bigfile tablespaces, including shadow tablespaces which store lost write protection tracking data. It lets you increase or decrease the size of the single data file to an absolute size. Use `K`, `M`, `G`, or `T` to specify the size in kilobytes, megabytes, gigabytes, or terabytes, respectively.

To change the size of a newly added data file or temp file in smallfile tablespaces, use the `ALTER DATABASE ... autoextend_clause` (see *database_file_clauses*).

> **See Also:**
>
> BIGFILE | SMALLFILE for information on bigfile tablespaces

COALESCE

For each data file in the tablespace, this clause combines all contiguous free extents into larger contiguous extents.

SHRINK SPACE Clause

This clause is valid only for temporary tablespaces. It lets you reduce the amount of space the tablespace is taking. In the optional `KEEP` clause, the *size_clause* defines the lower bound that a tablespace can be shrunk to. It is the opposite of `MAXSIZE` for an autoextensible tablespace. If you omit the `KEEP` clause, then the database will attempt to shrink the tablespace as much as possible as long as other tablespace storage attributes are satisfied.

RENAME Clause

Use this clause to rename *tablespace*. This clause is valid only if *tablespace* and all its data files are online and the `COMPATIBLE` parameter is set to 10.0.0 or greater. You can rename both permanent and temporary tablespaces.

If *tablespace* is read only, then Oracle Database does not update the data file headers to reflect the new name. The alert log will indicate that the data file headers have not been updated.

> **Note:**
>
> If you re-create the control file, and if the data files that Oracle Database uses for this purpose are restored backups whose headers reflect the old tablespace name, then the re-created control file will also reflect the old tablespace name. However, after the database is fully recovered, the control file will reflect the new name.

If *tablespace* has been designated as the undo tablespace for any instance in an Oracle Real Application Clusters (Oracle RAC) environment, and if a server parameter file was used to start up the database, then Oracle Database changes the value of the `UNDO_TABLESPACE` parameter for that instance in the server parameter file (`SPFILE`) to reflect the new tablespace name. If a single-instance database is using a parameter file (pfile) instead of an spfile, then the database puts a message in the alert log advising the database administrator to change the value manually in the pfile.

> **Note:**
>
> The `RENAME` clause does not change the value of the `UNDO_TABLESPACE` parameter in the running instance. Although this does not affect the functioning of the undo tablespace, Oracle recommends that you issue the following statement to manually change the value of `UNDO_TABLESPACE` to the new tablespace name for the duration of the instance:
>
> ```
> ALTER SYSTEM SET UNDO_TABLESPACE = new_tablespace_name SCOPE = MEMORY;
> ```
>
> You only need to issue this statement once. If the `UNDO_TABLESPACE` parameter is set to the new tablespace name in the pfile or spfile, then the parameter will be set correctly when the instance is next restarted.

Restriction on Renaming Tablespaces

You cannot rename the `SYSTEM` or `SYSAUX` tablespaces.

BACKUP Clauses

Use these clauses to move all data files in a tablespace into or out of online (sometimes called hot) backup mode.

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for information on restarting the database without media recovery
> - `ALTER DATABASE` "BACKUP Clauses" for information on moving all data files in the database into and out of online backup mode
> - `ALTER DATABASE` *alter_datafile_clause* for information on taking individual data files out of online backup mode

BEGIN BACKUP

Specify `BEGIN BACKUP` to indicate that an open backup is to be performed on the data files that make up this tablespace. This clause does not prevent users from accessing the tablespace. You must use this clause before beginning an open backup.

Restrictions on Beginning Tablespace Backup

Beginning tablespace backup is subject to the following restrictions:

- You cannot specify this clause for a read-only tablespace or for a temporary locally managed tablespace.
- While the backup is in progress, you cannot take the tablespace offline normally, shut down the instance, or begin another backup of the tablespace.

> **See Also:**
>
> "Backing Up Tablespaces: Examples"

END BACKUP

Specify `END BACKUP` to indicate that an online backup of the tablespace is complete. Use this clause as soon as possible after completing an online backup. Otherwise, if an instance failure or `SHUTDOWN ABORT` occurs, then Oracle Database assumes that media recovery (possibly requiring archived redo log) is necessary at the next instance startup.

Restriction on Ending Tablespace Backup

You cannot use this clause on a read-only tablespace.

datafile_tempfile_clauses

The tablespace file clauses let you add or modify a data file or temp file.

ADD Clause

Specify `ADD` to add to the tablespace a data file or temp file specified by *`file_specification`*. Use the *`datafile_tempfile_spec`* form of *`file_specification`* (see *file_specification*) to list regular data files and temp files in an operating system file system or to list Oracle Automatic Storage Management disk group files.

For locally managed temporary tablespaces, this is the only clause you can specify at any time.

If you omit *`file_specification`*, then Oracle Database creates an Oracle Managed File of 100M with `AUTOEXTEND` enabled.

You can add a data file or temp file to a locally managed tablespace that is online or to a dictionary managed tablespace that is online or offline. Ensure the file is not in use by another database.

Restriction on Adding Data Files and Temp Files

You cannot specify this clause for a bigfile (single-file) tablespace, as such a tablespace has only one data file or temp file.

> **Note:**
>
> On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

> **See Also:**
>
> *file_specification* , "Adding and Dropping Data Files and Temp Files: Examples", and "Adding an Oracle-managed Data File: Example"

DROP Clause

Specify `DROP` to drop from the tablespace an empty data file or temp file specified by *`filename`* or *`file_number`*. This clause causes the data file or temp file to be removed from the data dictionary and deleted from the operating system. The database must be open at the time this clause is specified.

The `ALTER TABLESPACE ... DROP TEMPFILE` statement is equivalent to specifying the `ALTER DATABASE TEMPFILE ... DROP INCLUDING DATAFILES`.

Restrictions on Dropping Files

To drop a data file or temp file, the data file or temp file:

- Must be empty.
- Cannot be the first data file that was created in the tablespace. In such cases, drop the tablespace instead.
- Cannot be in a read-only tablespace that was migrated from dictionary managed to locally managed. Dropping a data file from all other read-only tablespaces is supported.
- Cannot be offline.

> **See Also:**
>
> - `ALTER DATABASE` *alter_tempfile_clause* for additional information on dropping temp files
> - *Oracle Database Administrator's Guide* for information on data file numbers and for guidelines on managing data files
> - "Adding and Dropping Data Files and Temp Files: Examples"

SHRINK TEMPFILE Clause

This clause is valid only when altering a temporary tablespace. It lets you reduce the amount of space the specified temp file is taking. In the optional `KEEP` clause, the *`size_clause`* defines the lower bound that the temp file can be shrunk to. It is the opposite of `MAXSIZE` for an autoextensible tablespace. If you omit the `KEEP` clause, then the database will attempt to shrink the temp file as much as possible as long as other storage attributes are satisfied.

RENAME DATAFILE Clause

Specify `RENAME DATAFILE` to rename one or more of the tablespace data files. The database must be open, and you must take the tablespace offline before renaming it. Each *`filename`* must fully specify a data file using the conventions for filenames on your operating system.

This clause merely associates the tablespace with the new file rather than the old one. This clause does not actually change the name of the operating system file. You must change the name of the file through your operating system.

> **See Also:**
>
> "Moving and Renaming Tablespaces: Example"

ONLINE | OFFLINE Clauses

Use these clauses to take all data files or temp files in the tablespace offline or put them online. These clauses have no effect on the `ONLINE` or `OFFLINE` status of the tablespace itself.

The database must be mounted. If *`tablespace`* is `SYSTEM`, or an undo tablespace, or the default temporary tablespace, then the database must not be open.

tablespace_logging_clauses

Use these clauses to set or change the logging characteristics of the tablespace.

logging_clause

Specify `LOGGING` if you want logging of all tables, indexes, and partitions within the tablespace. The tablespace-level logging attribute can be overridden by logging specifications at the table, index, and partition levels.

When an existing tablespace logging attribute is changed by an `ALTER TABLESPACE` statement, all tables, indexes, and partitions created *after* the statement will have the new default logging attribute (which you can still subsequently override). The logging attribute of existing objects is not changed.

If the tablespace is in `FORCE LOGGING` mode, then you can specify `NOLOGGING` in this statement to set the default logging mode of the tablespace to `NOLOGGING`, but this will not take the tablespace out of `FORCE LOGGING` mode.

[NO] FORCE LOGGING

Use this clause to put the tablespace in force logging mode or take it out of force logging mode. The database must be open and in `READ WRITE` mode. Neither of these settings changes the default `LOGGING` or `NOLOGGING` mode of the tablespace.

Restriction on Force Logging Mode

You cannot specify `FORCE LOGGING` for an undo or a temporary tablespace.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information on when to use `FORCE LOGGING` mode and "Changing Tablespace Logging Attributes: Example"

tablespace_group_clause

This clause is valid only for locally managed temporary tablespaces. Use this clause to add *`tablespace`* to or remove it from the *`tablespace_group_name`* tablespace group.

- Specify a group name to indicate that *tablespace* is a member of this tablespace group. If *tablespace_group_name* does not already exist, then Oracle Database implicitly creates it when you alter tablespace to be a member of it.
- Specify an empty string (' ') to remove *tablespace* from the *tablespace_group_name* tablespace group.

Restriction on Tablespace Groups

You cannot specify a tablespace group for a permanent tablespace or for a dictionary-managed temporary tablespace.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information on tablespace groups and "Assigning a Tablespace Group: Example"

tablespace_state_clauses

Use these clauses to set or change the state of the tablespace.

ONLINE | OFFLINE

Specify `ONLINE` to bring the tablespace online. Specify `OFFLINE` to take the tablespace offline and prevent further access to its segments. When you take a tablespace offline, all of its data files are also offline.

> **Note:**
>
> Before taking a tablespace offline for a long time, consider changing the tablespace allocation of any users who have been assigned the tablespace as either a default or temporary tablespace. While the tablespace is offline, such users cannot allocate space for objects or sort areas in the tablespace. See ALTER USER for more information on allocating tablespace quota to users.

Restriction on Taking Tablespaces Offline

You cannot take a temporary tablespace offline.

OFFLINE NORMAL

Specify `NORMAL` to flush all blocks in all data files in the tablespace out of the system global area (SGA). You need not perform media recovery on this tablespace before bringing it back online. This is the default.

OFFLINE TEMPORARY

If you specify `TEMPORARY`, then Oracle Database performs a checkpoint for all online data files in the tablespace but does not ensure that all files can be written. Files that are offline when you issue this statement may require media recovery before you bring the tablespace back online.

OFFLINE IMMEDIATE

If you specify IMMEDIATE, then Oracle Database does not ensure that tablespace files are available and does not perform a checkpoint. You must perform media recovery on the tablespace before bringing it back online.

> **Note:**
>
> The FOR RECOVER setting for ALTER TABLESPACE ... OFFLINE has been deprecated. The syntax is supported for backward compatibility. However, Oracle recommends that you use the transportable tablespaces feature for tablespace recovery.

> **See Also:**
>
> *Oracle Database Backup and Recovery User's Guide* for information on using transportable tablespaces to perform media recovery

READ ONLY | READ WRITE

Specify READ ONLY to place the tablespace in **transition read-only mode**. In this state, existing transactions can complete (commit or roll back), but no further DML operations are allowed to the tablespace except for rollback of existing transactions that previously modified blocks in the tablespace. You cannot make the SYSAUX, SYSTEM, or temporary tablespaces READ ONLY.

When a tablespace is read only, you can copy its files to read-only media. You must then rename the data files in the control file to point to the new location by using the SQL statement ALTER DATABASE ... RENAME.

> **See Also:**
>
> - *Oracle Database Concepts* for more information on read-only tablespaces
> - ALTER DATABASE

Specify READ WRITE to indicate that write operations are allowed on a previously read-only tablespace.

PERMANENT | TEMPORARY

Specify PERMANENT to indicate that the tablespace is to be converted from a temporary to a permanent tablespace. A permanent tablespace is one in which permanent database objects can be stored. This is the default when a tablespace is created.

Specify TEMPORARY to indicate that the tablespace is to be converted from a permanent to a temporary tablespace. A temporary tablespace is one in which no permanent database objects can be stored. Objects in a temporary tablespace persist only for the duration of the session.

Restrictions on Temporary Tablespaces

Temporary tablespaces are subject to the following restrictions:

- You cannot specify TEMPORARY for the SYSAUX tablespace.

- If *tablespace* was not created with a standard block size, then you cannot change it from permanent to temporary.
- You cannot specify TEMPORARY for a tablespace in FORCE LOGGING mode.

autoextend_clause

This clause is valid only for bigfile (single-file) tablespaces. Use this clause to enable or disable autoextension of the single data file in the tablespace. To enable or disable autoextension of a newly added data file or temp file in smallfile tablespaces, use the *autoextend_clause* of the *database_file_clauses* in the ALTER DATABASE statement.

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for information about bigfile (single-file) tablespaces
> - *file_specification* for more information about the *autoextend_clause*

flashback_mode_clause

Use this clause to specify whether this tablespace should participate in any subsequent FLASHBACK DATABASE operation.

- For you to turn FLASHBACK mode on, the database must be mounted and closed.
- For you to turn FLASHBACK mode off, the database must be mounted, either open READ WRITE or closed.

This clause is not valid for temporary tablespaces.

Refer to CREATE TABLESPACE for more complete information on this clause.

> **See Also:**
>
> *Oracle Database Backup and Recovery User's Guide* for more information about Flashback Database

tablespace_retention_clause

This clause has the same semantics in CREATE TABLESPACE and ALTER TABLESPACE statements. Refer to tablespace_retention_clause in the documentation on CREATE TABLESPACE.

alter_tablespace_encryption

These clauses let you encrypt, decrypt, or rekey the tablespace.

ONLINE is the default for ALTER TABLESPACE ENCRYPTION.

ONLINE

- Specify ENCRYPT to encrypt the tablespace. The tablespace must be unencrpyted.

- Specify `REKEY` to encrypt an encrypted the tablespace using a different encryption algorithm. The tablespace must have been encrypted when it was created or encrypted with online conversion (`ONLINE ENCRYPT`).
- Specify `DECRYPT` to decrypt the tablespace. The tablespace must have been encrypted when it was created or encrypted with online conversion (`ONLINE ENCRYPT`).

FINISH

If an online conversion operation is interrupted, use the `FINISH` clause to finish the operation. The `ENCRYPT`, `DECRYPT`, `REKEY`, and *`ts_file_name_convert`* clauses have the same semantics here as they have for the `ONLINE` clause.

You can use `FINISH` to encrypt, decrypt, or rekey the tablespace with online conversion. The tablespace must be online. The online conversion method creates a new datafile for each datafile in the tablespace. Therefore, before using this clause, ensure that the amount of free disk space is greater than or equal to the amount of disk space currently used by the tablespace.

OFFLINE

This clause lets you encrypt or decrypt the tablespace with offline conversion. The tablespace must be offline or the database must be mounted, but not open. The offline conversion method does not use auxiliary disk space or files; it operates directly on the existing datafiles. Therefore, you should perform a full backup of the tablespace before converting it offline.

- Specify `ENCRYPT` to encrypt the tablespace. You can encrypt the tablespace using `AES128`, `AES192`, or `AES256` algorithms. The tablespace must be unencrpyted.
- Specify `DECRYPT` to decrypt the tablespace. The tablespace must have been previously encrypted with offline conversion (`OFFLINE ENCRYPT`).

If an offline conversion operation is interrupted, then you can reissue the offline conversion command to finish the operation.

tablespace_encryption_spec

Use this clause to specify the encryption algorithm to use when encrypting or rekeying the tablespace. If you omit this clause, then the datafiles will be encrypted using the `AES128` algorithm. Refer to *tablespace_encryption_spec* in the documentation on `CREATE TABLESPACE` for the full semantics of this clause.

ts_file_name_convert

Use this clause to determine how the database generates the names of the new datafiles that are created during online conversion.

If `FILE_NAME_CONVERT` is omitted, Oracle will internally select a name for the auxiliary file, and later rename it back to the original name.

- For *`filename_pattern`*, specify a string found in an existing datafile name.
- For *`replacement_filename_pattern`*, specify a replacement string. Oracle Database will replace *`filename_pattern`* with *`replacement_filename_pattern`* when naming the new datafile.
- Specify `KEEP` to retain the original files after the tablespace conversion is finished. If you omit this clause, then the original files are deleted when the conversion is finished.

Restriction on the *alter_tablespace_encryption* Clause

You cannot perform offline or online conversions on temporary tablespaces.

lost_write_protection

Before you can enable lost write protection on individual tablespaces, you must first enable the database for shadow lost write protection with `ALTER DATABASE`. Then you must create at least one shadow tablespace in that database using the `CREATE TABLESPACE` command.

After these steps you can use `ALTER TABLESPACE` to enable, remove, and suspend lost write protection on the shadow tablespace.

Example: Enable Lost Write Protection for a Tablespace

The following command enables lost write protection for the `tbsu1` tablespace.

```
ALTER TABLESPACE tbsu1 ENABLE LOST WRITE PROTECTION
```

Example: Remove Lost Write Protection for a Shadow Tablespace

The following command removes lost write protection for the `tbsu1` tablespace.

```
ALTER TABLESPACE tbsu1 REMOVE LOST WRITE PROTECTION
```

Example: Suspend Lost Write Protection for a Shadow Tablespace

The following command suspends lost write protection for the `tbsu1` tablespace.

```
ALTER TABLESPACE tbsu1 SUSPEND LOST WRITE PROTECTION
```

> **See Also:**
>
> *Managing Lost Write Protection with Shadow Tablespaces*

Examples

Backing Up Tablespaces: Examples

The following statement signals to the database that a backup is about to begin:

```
ALTER TABLESPACE tbs_01
    BEGIN BACKUP;
```

The following statement signals to the database that the backup is finished:

```
ALTER TABLESPACE tbs_01
   END BACKUP;
```

Moving and Renaming Tablespaces: Example

This example moves and renames a data file associated with the `tbs_02` tablespace, created in "Enabling Autoextend for a Tablespace: Example", from `diskb:tbs_f5.dbf` to `diska:tbs_f5.dbf`:

1. Take the tablespace offline using an `ALTER TABLESPACE` statement with the `OFFLINE` clause:

   ```
   ALTER TABLESPACE tbs_02 OFFLINE NORMAL;
   ```

2. Copy the file from `diskb:tbs_f5.dbf` to `diska:tbs_f5.dbf` using your operating system commands.

3. Rename the data file using an `ALTER TABLESPACE` statement with the `RENAME DATAFILE` clause:

```
ALTER TABLESPACE tbs_02
  RENAME DATAFILE 'diskb:tbs_f5.dbf'
  TO              'diska:tbs_f5.dbf';
```

4. Bring the tablespace back online using an `ALTER TABLESPACE` statement with the `ONLINE` clause:

```
ALTER TABLESPACE tbs_02 ONLINE;
```

Adding and Dropping Data Files and Temp Files: Examples

The following statement adds a data file to the tablespace. When more space is needed, new 10-kilobytes extents will be added up to a maximum of 100 kilobytes:

```
ALTER TABLESPACE tbs_03
    ADD DATAFILE 'tbs_f04.dbf'
    SIZE 100K
    AUTOEXTEND ON
    NEXT 10K
    MAXSIZE 100K;
```

The following statement drops the empty data file:

```
ALTER TABLESPACE tbs_03
    DROP DATAFILE 'tbs_f04.dbf';
```

The following statements add a temp file to the temporary tablespace created in "Creating a Temporary Tablespace: Example" and then drops the temp file:

```
ALTER TABLESPACE temp_demo ADD TEMPFILE 'temp05.dbf' SIZE 5 AUTOEXTEND ON;

ALTER TABLESPACE temp_demo DROP TEMPFILE 'temp05.dbf';
```

Managing Space in a Temporary Tablespace: Example

The following statement manages the space in the temporary tablespace created in "Creating a Temporary Tablespace: Example" using the `SHRINK SPACE` clause. The `KEEP` clause is omitted, so the database will attempt to shrink the tablespace as much as possible as long as other tablespace storage attributes are satisfied.

```
ALTER TABLESPACE temp_demo SHRINK SPACE;
```

Adding an Oracle-managed Data File: Example

The following example adds an Oracle-managed data file to the `omf_ts1` tablespace (see "Creating Oracle Managed Files: Examples" for the creation of this tablespace). The new data file is 100M and is autoextensible with unlimited maximum size:

```
ALTER TABLESPACE omf_ts1 ADD DATAFILE;
```

Changing Tablespace Logging Attributes: Example

The following example changes the default logging attribute of a tablespace to `NOLOGGING`:

```
ALTER TABLESPACE tbs_03 NOLOGGING;
```

Altering a tablespace logging attribute has no affect on the logging attributes of the existing schema objects within the tablespace. The tablespace-level logging attribute can be overridden by logging specifications at the table, index, and partition levels.

Changing Undo Data Retention: Examples

The following statement changes the undo data retention for tablespace `undots1` to normal undo data behavior:

```
ALTER TABLESPACE undots1
  RETENTION NOGUARANTEE;
```

The following statement changes the undo data retention for tablespace `undots1` to behavior that preserves unexpired undo data:

```
ALTER TABLESPACE undots1
  RETENTION GUARANTEE;
```

ALTER TABLESPACE SET

> **Note:**
>
> This SQL statement is valid only if you are using Oracle Sharding. For more information on Oracle Sharding, refer to *Oracle Database Administrator's Guide*.

Purpose

Use the `ALTER TABLESPACE SET` statement to change an attribute of an existing tablespace set. The attribute change is applied to all tablespaces in the tablespace set.

> **See Also:**
>
> CREATE TABLESPACE SET and DROP TABLESPACE SET

Prerequisites

You must be connected to a shard catalog database as an SDB user.

If you have the `ALTER TABLESPACE` system privilege, then you can perform any `ALTER TABLESPACE SET` operation. If you have the `MANAGE TABLESPACE` system privilege, then you can only perform the following operations:

- Take all tablespaces in a tablespace set online or offline
- Begin or end a backup
- Make all tablespaces in a tablespace set read only or read write
- Set the default logging mode of all tablespaces in a tablespace set to `LOGGING` or `NOLOGGING`
- Put all tablespaces in a tablespace set in force logging mode or take them out of force logging mode
- Resize all data files for a tablespace set
- Enable or disable autoextension of all data files for a tablespace set

Before you can make a tablespace set read only, the following conditions must be met:

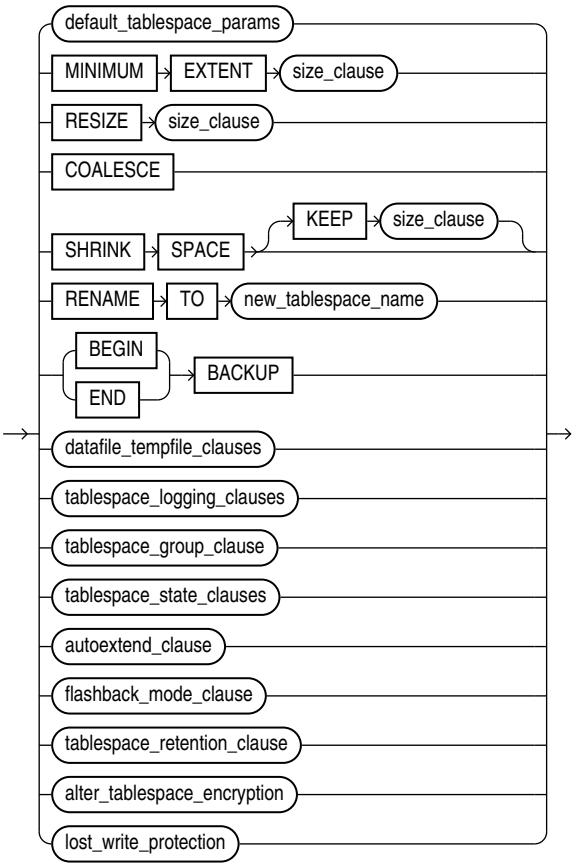
- The tablespaces in the tablespace set must be online.

- The tablespace set must not contain any active rollback segments. Additionally, because the rollback segments of a read-only tablespace set are not accessible, Oracle recommends that you drop the rollback segments before you make a tablespace set read only.
- The tablespace set must not be involved in an open backup, because the end of a backup updates the header file of all data files in the tablespace set.

Syntax

***alter_tablespace_set*::=**

***alter_tablespace_attrs*::=**



(See the following clauses of `ALTER TABLESPACE`: *default_tablespace_params*::=, *size_clause*::=, *datafile_tempfile_clauses*::=, *tablespace_logging_clauses*::=, *tablespace_state_clauses*::=, *autoextend_clause*::=, *alter_tablespace_encryption*::=)

Semantics

tablespace_set

Specify the name of the tablespace set to be altered.

alter_tablespace_attrs

Use this clause to change an attribute for all tablespaces in the tablespace set.

The subclauses of *alter_tablespace_attrs* have the same semantics here as for the ALTER TABLESPACE statement, with the following exceptions:

- You cannot specify the following subclauses for tablespace sets:
  - MINIMUM EXTENT *size_clause*
  - SHRINK SPACE [KEEP *size_clause*]
  - *tablespace_group_clause*
  - *flashback_mode_clause*
  - *tablespace_retention_clause*
- For the *datafile_tempfile_clauses*, only the following subclauses are supported for tablespace sets:
  - RENAME DATAFILE
  - DATAFILE { ONLINE | OFFLINE }
- For the *tablespace_state_clauses*, the PERMANENT and TEMPORARY subclauses are not supported for tablespace sets.

> **See Also:**
>
> *alter_tablespace_attrs* in the documentation on ALTER TABLESPACE for the full semantics of this clause

Examples

Altering a Tablespace Set: Example

The following statement puts all tablespaces in tablespace set ts1 in force logging mode:

```
ALTER TABLESPACE SET ts1
  FORCE LOGGING;
```

ALTER TRIGGER

Purpose

Triggers are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the ALTER TRIGGER statement to enable, disable, or compile a database trigger.

> **Note:**
>
> This statement does not change the declaration or definition of an existing trigger. To redeclare or redefine a trigger, use the `CREATE TRIGGER` statement with the `OR REPLACE` keywords.

> **See Also:**
>
> - CREATE TRIGGER for information on creating a trigger
> - DROP TRIGGER for information on dropping a trigger
> - *Oracle Database Concepts* for general information on triggers

Prerequisites

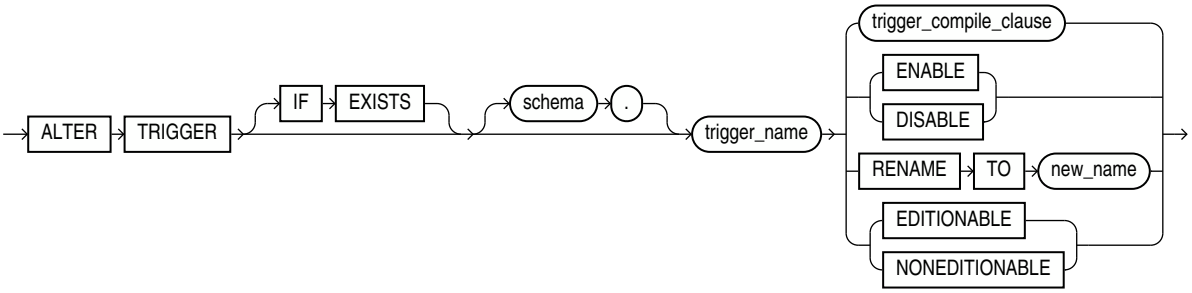
The trigger must be in your own schema or you must have `ALTER ANY TRIGGER` system privilege.

In addition, to alter a trigger on `DATABASE`, you must have the `ADMINISTER DATABASE TRIGGER` privilege.

> **See Also:**
>
> CREATE TRIGGER for more information on triggers based on `DATABASE` triggers

Syntax

***alter_trigger*::=**



(*trigger_compile_clause*: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

schema

Specify the schema containing the trigger. If you omit *`schema`*, then Oracle Database assumes the trigger is in your own schema.

trigger_name

Specify the name of the trigger to be altered.

trigger_compile_clause

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling triggers.

ENABLE | DISABLE

Specify `ENABLE` to enable the trigger. You can also use the `ENABLE ALL TRIGGERS` clause of `ALTER TABLE` to enable all triggers associated with a table. See ALTER TABLE.

Specify `DISABLE` to disable the trigger. You can also use the `DISABLE ALL TRIGGERS` clause of `ALTER TABLE` to disable all triggers associated with a table.

RENAME Clause

Specify `RENAME TO` *`new_name`* to rename the trigger. Oracle Database renames the trigger and leaves it in the same state it was in before being renamed.

When you rename a trigger, the database rebuilds the remembered source of the trigger in the `USER_SOURCE`, `ALL_SOURCE`, and `DBA_SOURCE` data dictionary views. As a result, comments and formatting may change in the `TEXT` column of those views even though the trigger source did not change.

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the trigger becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `TRIGGER` in *`schema`*. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

Restriction on NONEDITIONABLE

You cannot specify `NONEDITIONABLE` for a crossedition trigger.

ALTER TYPE

Purpose

Object types are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `ALTER TYPE` statement to add or drop member attributes or methods. You can change the existing properties (`FINAL` or `INSTANTIABLE`) of an object type, and you can modify the scalar attributes of the type.

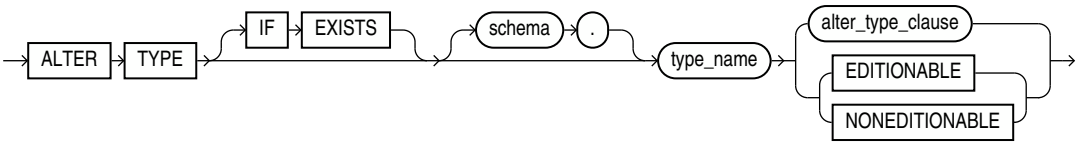
You can also use this statement to recompile the specification or body of the type or to change the specification of an object type by adding new object member subprogram specifications.

Prerequisites

The object type must be in your own schema and you must have `CREATE TYPE` or `CREATE ANY TYPE` system privilege, or you must have `ALTER ANY TYPE` system privileges.

Syntax

***alter_type*::=**



(*alter_type_clause*: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

schema

Specify the schema that contains the type. If you omit *schema*, then Oracle Database assumes the type is in your current schema.

type_name

Specify the name of an object type, a nested table type, or a varray type.

Restriction on *type_name*

You cannot evolve an editioned object type. The `ALTER TYPE` statement fails with ORA-22348 if either of the following is true:

- The type is an editioned object type and the `ALTER TYPE` statement has no *type_compile_clause*. You can use the `ALTER TYPE` statement to recompile an editioned object type, but not for any other purpose.
- The type has a dependent that is an editioned object type and the `ALTER TYPE` statement has a `CASCADE` clause.

Refer to *Oracle Database PL/SQL Language Reference* for more information on the *type_compile_clause* and the `CASCADE` clause.

alter_type_clause

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling object types.

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the type becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `TYPE` in *`schema`*. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

ALTER USER

Purpose

Use the `ALTER USER` statement:

- To change the authentication or database resource characteristics of a database user
- To permit a proxy server to connect as a client without authentication
- In an Oracle Automatic Storage Management (Oracle ASM) cluster, to change the password of a user in the password file that is local to the Oracle ASM instance of the current node

> **See Also:**
>
> *Oracle Database Security Guide* for detailed information about user authentication methods

Prerequisites

In general, you must have the `ALTER USER` system privilege. However, the current user can change his or her own password without this privilege.

To change the `SYS` password, password file must exist, and an account granted alter user privilege must have the `SYSDBA` administrative role in order to have the ability to change `SYS` password.

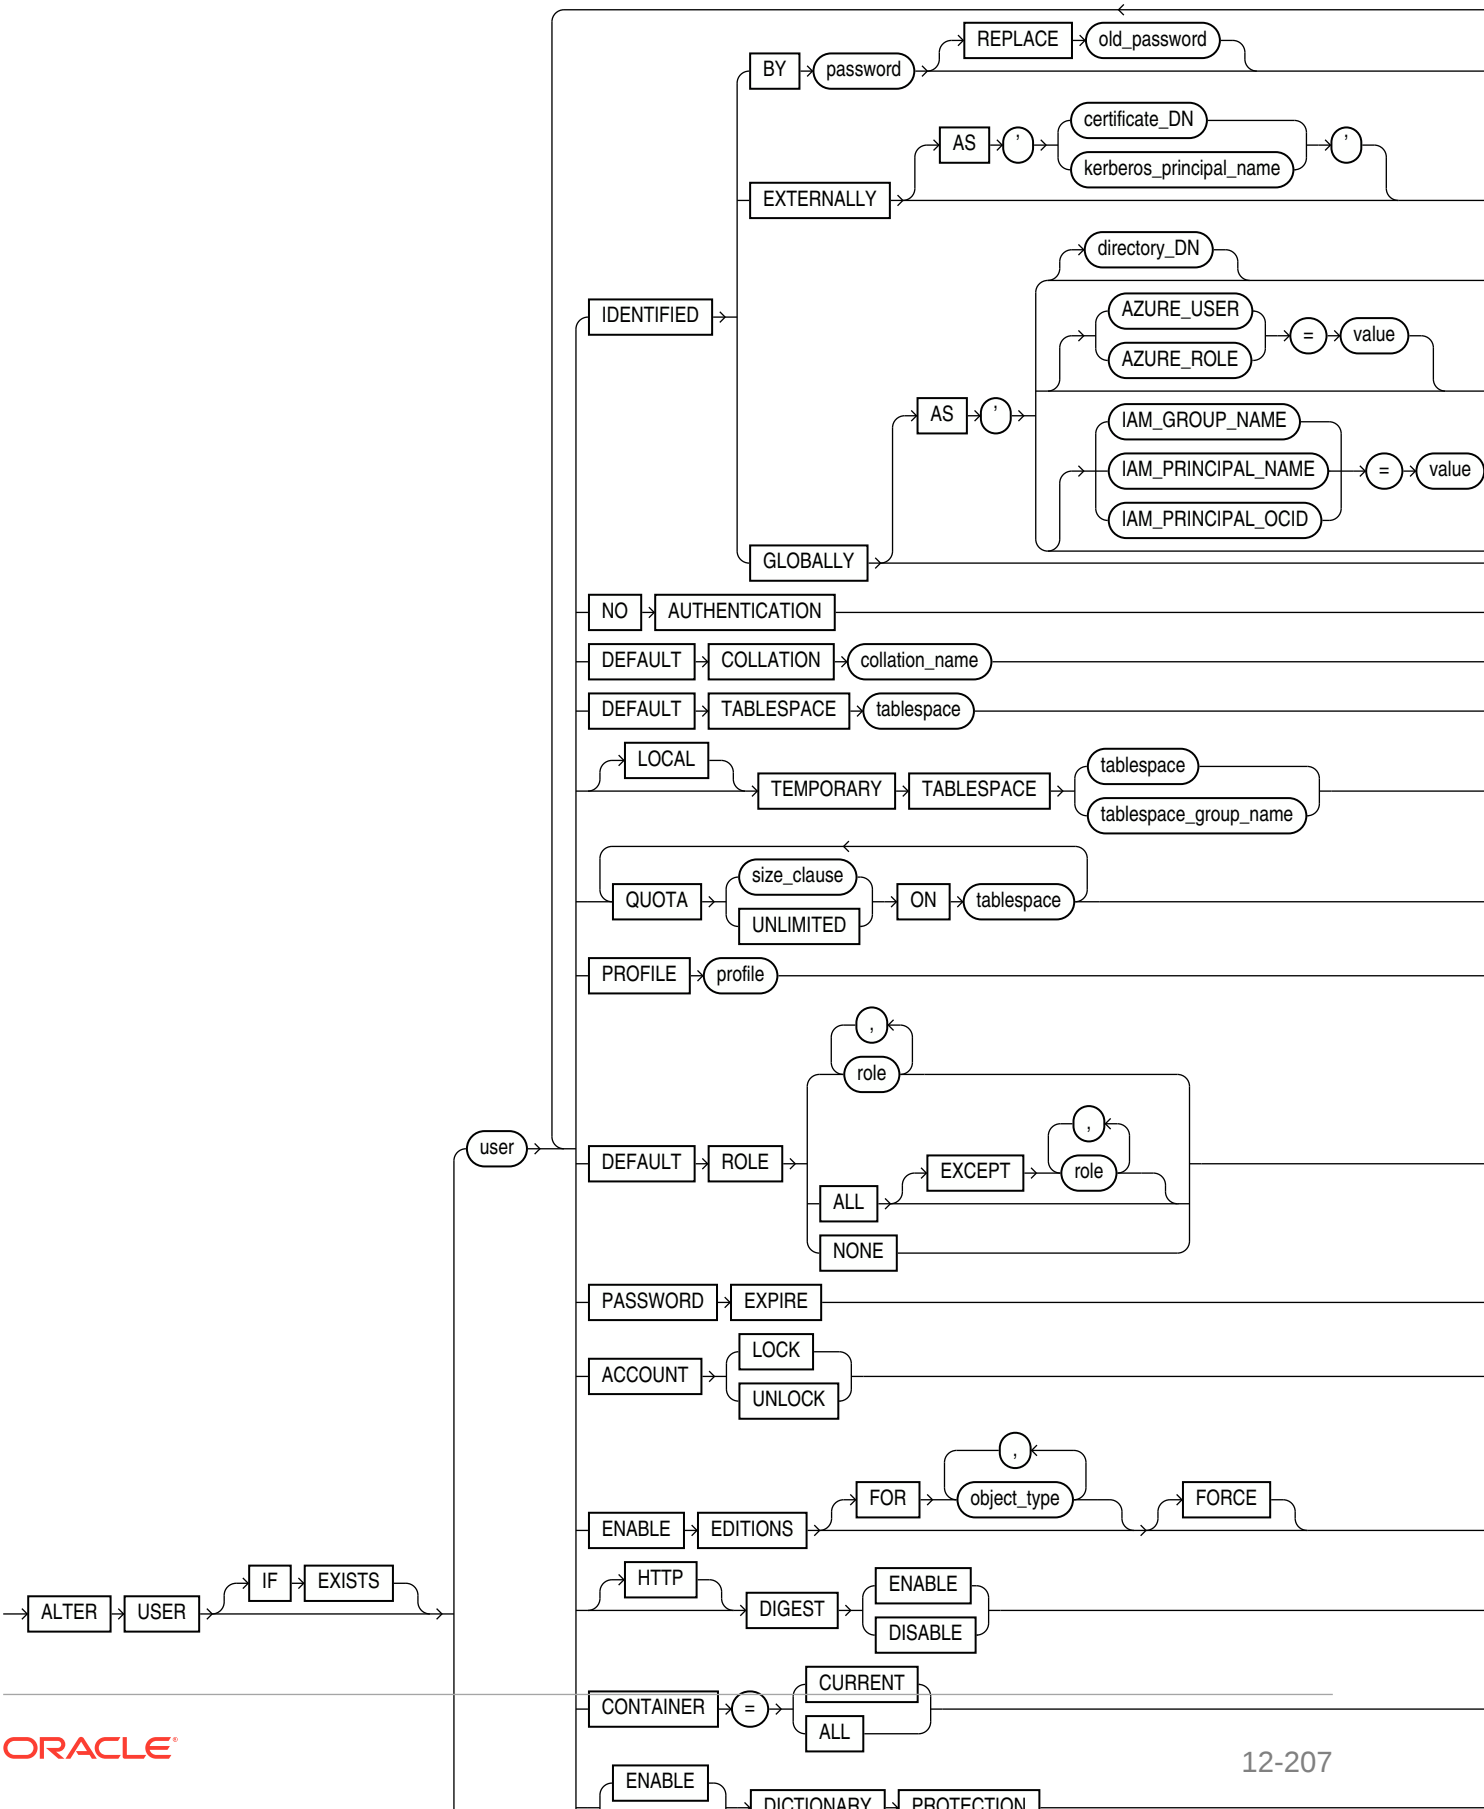
You must be authenticated `AS SYSASM` to change the password of a user other than yourself in an Oracle ASM instance password file.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). If the current container is the root, then you can specify `CONTAINER = ALL` or `CONTAINER = CURRENT`. If the current container is a pluggable database (PDB), then you can specify only `CONTAINER = CURRENT`.

To set and modify `CONTAINER_DATA` attributes using the *`container_data_clause`*, you must be connected to a CDB and the current container must be the root.

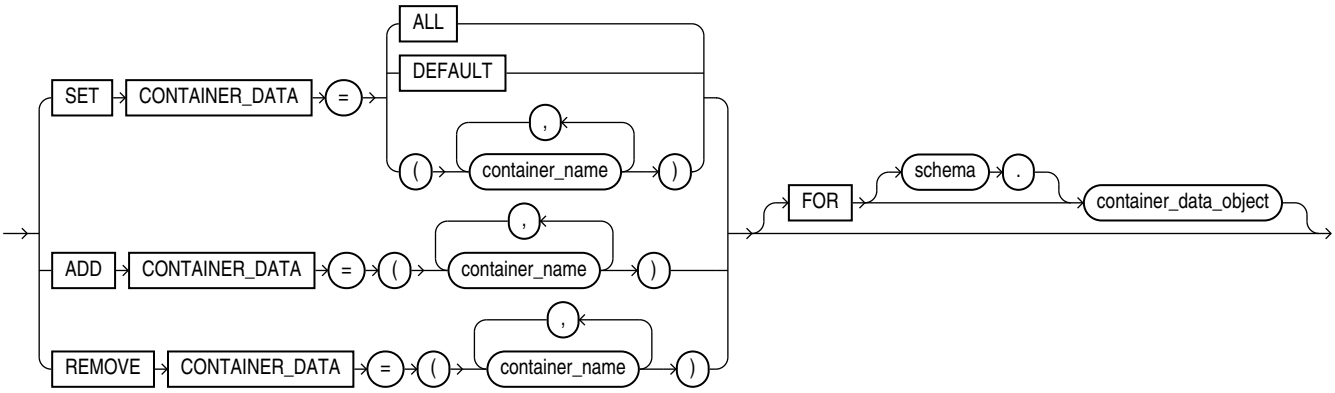
Syntax

***alter_user*::=**

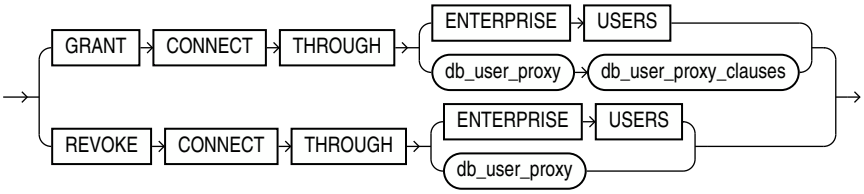


(*size_clause*::=)

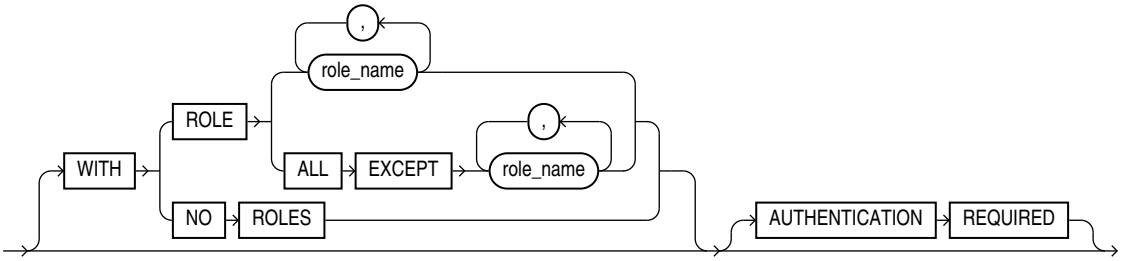
***container_data_clause*::=**



***proxy_clause*::=**



***db_user_proxy_clauses*::=**



Semantics

The keywords, parameters, and clauses described in this section are unique to `ALTER USER` or have different semantics than they have in `CREATE USER`. Keywords, parameters, and clauses that do not appear here have the same meaning as in the `CREATE USER` statement.

> **Note:**
>
> Oracle recommends that user names and passwords be encoded in ASCII or EBCDIC characters only, depending on your platform.

> **See Also:**
>
> CREATE USER for information on the keywords and parameters and CREATE PROFILE for information on assigning limits on database resources to a user

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

IDENTIFIED Clause

BY *password*

Specify `BY` *`password`* to specify a new password for the user. Passwords are case sensitive. Any subsequent `CONNECT` string used to connect this user to the database must specify the password using the same case (upper, lower, or mixed) that is used in this `ALTER USER` statement. Passwords can contain single-byte, or multibyte characters, or both from your database character set.

> **Note:**
>
> Oracle Database expects a different timestamp for each resetting of a particular password. If you reset one password multiple times within one second (for example, by cycling through a set of passwords using a script), then the database may return an error message that the password cannot be reused. For this reason, Oracle recommends that you avoid using scripts to reset passwords.

You can omit the `REPLACE` clause if you are setting your own password or you have the `ALTER USER` system privilege and you are changing another user's password. However, unless you have the `ALTER USER` system privilege, you must always specify the `REPLACE` clause if a password complexity verification function has been enabled, either by running the `UTLPWDMG.SQL` script or by specifying such a function in the `PASSWORD_VERIFY_FUNCTION` parameter of a profile that has been assigned to the user.

In an Oracle ASM cluster, you can use this clause to change the password of a user in the password file that is local to an Oracle ASM instance of the current node. You must be authenticated `AS SYSASM` to specify `IDENTIFIED BY` *`password`* without the `REPLACE` *`old_password`* clause. If you are not authenticated `AS SYSASM`, then you can only change your own password by specifying `REPLACE` *`old_password`*.

Oracle Database does not check the old password, even if you provide it in the `REPLACE` clause, unless you are changing your own existing password.

Changing a Password to Begin the Gradual Database Password Rollover Period

Prerequisite

Enable gradual database password rollover period by setting a non-zero value to the `PASSWORD_ROLLOVER_TIME` user profile parameter using `CREATE PROFILE` or `ALTER PROFILE` .

After you set the PASSWORD_ROLLOVER_TIME to specify the duration of the gradual password rollover period in the profile of the user, you can use the ALTER USER statement to change the user's password, which will allow clients to login using both the old password and the new password until the password rollover period expires.

During the password rollover period, you must propagate the new password to all clients (before the PASSWORD_ROLLOVER_TIME ends). If you successfully propagated the new password to all clients early (before the end of the password rollover period), then you can use the EXPIRE PASSWORD ROLLOVER PERIOD clause to end the password rollover (finalizing the password change, so that only the new password can be used).

Changing a Password During the Gradual Database Password Rollover Period

You can change the password during the password rollover period (before the rollover period expires) using ALTER USER with or without the REPLACE clause.

For example, say user u1 has an original password p1, and p2 is the new password that started the rollover process. Now you want to switch to p3 instead of p2. You can use any one of the statements to change the password to p3:

```
ALTER USER u1 IDENTIFIED BY p3;

ALTER USER u1 IDENTIFIED BY p3 REPLACE p1;

ALTER USER u1 IDENTIFIED BY p3 REPLACE p2;
```

After you change the password to p3, the user can log in using either p1 or p3. Logging in with p2 returns error Invalid credential or not authorized; logon denied and is recorded as a failed login attempt.

The rollover start time remains set to the password change timestamp, this is the time the password of the user was changed. The rollover start time and password change time are not affected by any further password change made during the password rollover period. The old password can be used for at most PASSWORD_ROLLOVER_TIME days.

> **See Also:**
>
> - *Oracle Database Security Guide* for guidelines on creating passwords
> - Configuring Authentication

GLOBALLY

Refer to CREATE USER for more information on this clause.

You can change a user's access verification method *from* IDENTIFIED GLOBALLY to either IDENTIFIED BY *password* or IDENTIFIED EXTERNALLY. You can change a user's access verification method *to* IDENTIFIED GLOBALLY from one of the other methods only if all external roles granted explicitly to the user are revoked.

EXTERNALLY

Refer to CREATE USER for more information on this clause.

> **See Also:**
>
> *Oracle Database Enterprise User Security Administrator's Guide* for more information on globally and externally identified users, "Changing User Identification: Example", and "Changing User Authentication: Examples"

NO AUTHENTICATION Clause

Use this clause to change an existing user account with authentication to a schema account without authentication to prevent logins to the account.

DEFAULT COLLATION Clause

Use this clause to change the default collation for the schema owned by the user. The new default collation is assigned to tables, views, and materialized views that are subsequently created in the schema. It does not influence default collations for existing tables views, and materialized views. Refer to the DEFAULT COLLATION Clause clause of `CREATE USER` for the full semantics of this clause.

DEFAULT TABLESPACE Clause

Use this clause to assign or reassign a tablespace for the user's permanent segments. This clause overrides any default tablespace that has been specified for the database.

Restriction on Default Tablespaces

You cannot specify a locally managed temporary tablespace, including an undo tablespace, or a dictionary-managed temporary tablespace, as a user's default tablespace.

[LOCAL] TEMPORARY TABLESPACE Clause

Use this clause to assign or reassign a temporary tablespace or tablespace group for the user's temporary segments.

- Specify *`tablespace`* to indicate the user's temporary tablespace. Specify `TEMPORARY TABLESPACE` to indicate a shared temporary tablespace. Specify `LOCAL TEMPORARY TABLESPACE` to indicate a local temporary tablespace. If you are connected to a CDB, then you can specify `CDB$DEFAULT` to use the CDB-wide default temporary tablespace.
- Specify *`tablespace_group_name`* to indicate that the user can save temporary segments in any tablespace in the tablespace group specified by *`tablespace_group_name`*. Local temporary tablespaces cannot be part of a tablespace group.

Restriction on User Temporary Tablespace

Any individual tablespace you assign or reassign as the user's temporary tablespace must be a temporary tablespace and must have a standard block size.

> **See Also:**
>
> "Assigning a Tablespace Group: Example"

DEFAULT ROLE Clause

Specify the roles enabled by default for the user at logon.This clause can contain only roles that have been granted directly to the user with a `GRANT` statement, or roles created by the user with the `CREATE ROLE` privilege. You cannot use the `DEFAULT ROLE` clause to specify:

- Roles not granted to the user
- Roles granted through other roles
- Roles managed by an external service (such as the operating system), or by the Oracle Internet Directory
- Roles that are enabled by the `SET ROLE` statement, such as password-authenticated roles and secure application roles

> **See Also:**
>
> CREATE ROLE

Assigning Default Roles to Common Users in a CDB

You can modify the default role assigned to a common user both in the current container and across all containers in a CDB.

While assigning a default role to a common user across all containers, `role` must be a common role that was commonly granted to the common user.

While assigning a default role to a common user in the current container, `role` must be one of the following:

- A local role that was granted to the common user in the current container
- A common role that was granted to the common user, either commonly or locally in the current container

EXPIRE PASSWORD ROLLOVER PERIOD Clause

You can manually expire the password rollover period with `EXPIRE PASSWORD ROLLOVER PERIOD`.

ENABLE EDITIONS

This clause is not reversible. Specify `ENABLE EDITIONS` to allow the user to create multiple versions of editionable objects in this schema using editions. Editionable objects in non-editions-enabled schemas cannot be editioned.

Use the `FOR` clause to specify one or more object types for which the user can create editionable objects. For a list of valid values for *`object_type`*, query the `V$EDITIONABLE_TYPES` dynamic performance view.

If you omit the `FOR` clause, then the types that become editionable in the schema are `VIEW`, `SYNONYM`, `PROCEDURE`, `FUNCTION`, `PACKAGE`, `PACKAGE BODY`, `TRIGGER`, `TYPE`, `TYPE BODY`, and `LIBRARY`.

To enable edition for other object types that are not enabled by default, you must explicitly specify the object type in the `FOR` clause.

Example: Enable Edition for Object Type not Enabled by Default

```
ALTER USER username ENABLE EDITIONS FOR SQL TRANSLATION PROFILE;
```

See Also:

- For more on the semantics of the ENABLE EDITIONS clause see the corresponding section in *CREATE USER*
- *Enabling Editions for a User*
- *Oracle Database Reference* for more information about the `V$EDITIONABLE_TYPES` dynamic performance view

If the schema to be editions-enabled contains any objects that are not editionable and that depend on editionable type objects in the schema, then you must specify `FORCE` to enable editions for this schema. In this case, all the objects that are not editionable and that depend on the editionable type objects in the schema being editions-enabled become invalid.

[HTTP] DIGEST Clause

This clause lets you enable or disable HTTP Digest Access Authentication for the user.

- Specify `ENABLE` to enable HTTP Digest Access Authentication. After specifing this clause, you must change the user's password. This causes the database to generate an HTTP Digest verifier for the new password. Only then will HTTP Digest Access Authentication take effect. One way to ensure that the user's password is changed after you issue this clause is to specify the `PASSWORD EXPIRE` clause in the same statement with the `HTTP DIGEST ENABLE` clause, as follows:

  ```
  ALTER USER user PASSWORD EXPIRE HTTP DIGEST ENABLE;
  ```

  This causes the database to prompt the user for a new password on his or her next attempt to log in to the database. After that, HTTP Digest Access Authentication will take effect for the user.
- Specify `DISABLE` to disable HTTP Digest Access Authentication for the user. You do not need to change the user's password in order for this clause to take effect. Specifying the `DISABLE` clause removes the HTTP Digest from dictionary tables.

  ```
  ALTER USER user PASSWORD EXPIRE HTTP DIGEST DISABLE;
  ```

Refer to [HTTP] DIGEST Clause in the documentation on `CREATE USER` for more information on this clause.

CONTAINER Clause

If the current container is a PDB, then you can specify `CONTAINER = CURRENT` to change the attributes of a local user, or the container-specific attributes (such as the default tablespace) of a common user, in the current container. If the current container is the root, then you can specify `CONTAINER = ALL` to change the attributes of a common user across the entire CDB. If you omit this clause and the current container is a PDB, then `CONTAINER = CURRENT` is the

default. If you omit this clause and the current container is the root, then CONTAINER = ALL is the default.

Restriction on Modifying Common Users in a CDB

Certain attributes of a common user must be modified for all the containers in a CDB and not for only some containers. Therefore, when you use any of the following clauses to modify a common user, ensure that you modify all of the containers by connecting to the root and specifying CONTAINER=ALL:

- IDENTIFIED clause
- PASSWORD clause
- [HTTP] DIGEST clause

ENABLE or DISABLE DICTIONARY PROTECTION

Use this clause to enable or disable dictionary protection on the created user. When a schema is dictionary protected, other users cannot use system privileges (including ANY privileges) on the schema, even if they have been granted the system privilege on the schema. Only the SELECT ANY DICTIONARY and ANALYZE ANY DICTIONARY system privileges can be used on a dictionary-protected schema. Users can still use object privileges on the schema, assuming that the user has been granted the object privilege on the schema. A user without the object privileges on the object but with corresponding system privileges will be denied access to the object with an insufficient privileges error.

By default, Oracle-maintained schemas have dictionary protection, but this protection can be temporarily removed if necessary. You cannot enable dictionary protection on a customer (Non-Oracle maintained) schema. You also cannot create a custom schema with dictionary protection enabled.

You must be logged in as user SYS with the SYSDBA administrative privilege in order to manage dictionary protection for Oracle-maintained schemas.

> **See Also:**
>
> - *Configuring Privilege and Role Authorization* of the *Oracle Database Security Guide*.

READ ONLY | READ WRITE

Specify READ ONLY to set read-only access to a local PDB user.

With read-only access, the local PDB user is not permitted to execute any write operations on the PDB they connect to. The session operates as if the database is open in read-only mode.

Specify READ WRITE to revoke READ ONLY access on a local user.

You must have the ALTER USER privilege to execute this statement.

You can view the state of a local user in the *_USERS view.

container_data_clause

The *container_data_clause* allows you the set and modify CONTAINER_DATA attributes for a common user. Use the FOR clause to indicate whether to set or modify the default

CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute. These attributes determine the set of containers (which can never exclude the root) whose data will be visible via CONTAINER_DATA objects to the specified common user when the current session is the root.

To specify the *container_data_clause*, the current session must be the root and you must specify CONTAINER = CURRENT.

SET CONTAINER_DATA

Use this clause to set the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute for a common user. When you specify this clause, you replace the existing value, if any, of the CONTAINER_DATA attribute.

Use *container_name* to specify one or more containers that will be accessible to the user.

Use ALL to specify that all current and future containers in the CDB will be accessible to the user.

Use DEFAULT to specify the default behavior, which is as follows:

- For a default CONTAINER_DATA attribute, the current container, that is, the root, and the CDB as a whole will be accessible to the user.
- For an object-specific CONTAINER_DATA attribute, the database will use the user's default CONTAINER_DATA attribute.

> **Note:**
>
> CONTAINER_DATA attributes that are set to DEFAULT are not visible in the DBA_CONTAINER_DATA view.

ADD CONTAINER_DATA

Use this clause to add containers to the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute for a common user. Use *container_name* to specify one or more containers to add.

You cannot use this clause if the default CONTAINER_DATA attribute is set to ALL. If you use this clause when the default CONTAINER_DATA attribute is set to DEFAULT, then CDB$ROOT will automatically be added to the set of containers, unless the set already contains CDB$ROOT.

You cannot use this clause if the object-specific CONTAINER_DATA attribute is set to ALL or DEFAULT.

REMOVE CONTAINER_DATA

Use this clause to remove containers from the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute for a common user. Use *container_name* to specify one or more containers to remove.

You cannot use this clause if the default CONTAINER_DATA attribute or object-specific CONTAINER_DATA attribute is set to ALL or DEFAULT.

FOR *container_data_object*

If you specify the FOR clause, then you can set and modify the object-specific CONTAINER_DATA attribute for *container_data_object* for a common user. *container_data_object* must be a

CONTAINER_DATA table or view. If you omit *schema*, then Oracle Database assumes that *container_data_object* is in your own schema.

If you omit the FOR clause, then you can set and modify the default CONTAINER_DATA attribute for a common user.

> **See Also:**
>
> *Oracle Database Security Guide* for more information about enabling common users to view information about PDB objects

proxy_clause

The *proxy_clause* lets you control the ability of an enterprise user (a user outside the database) or a database proxy (another database user) to connect as the database user being altered.

GRANT CONNECT THROUGH

Specify GRANT CONNECT THROUGH to allow the connection.

REVOKE CONNECT THROUGH

Specify REVOKE CONNECT THROUGH to prohibit the connection.

ENTERPRISE USER

This clause lets you expose *user* to proxy use by enterprise users. The administrator working in Oracle Internet Directory must then grant privileges for appropriate enterprise users to act on behalf of *user*.

db_user_proxy

This clause lets you expose *user* to proxy use by database user *db_user_proxy* (the proxy).

- The proxy will have all privileges that were directly granted to user.
- The proxy will have all roles associated with user, unless you specify the WITH clauses of *db_user_proxy_clauses* to limit the proxy to some or none of the roles of user. For each role associated with the proxy, if the role is enabled by default for *user* at login, then that role will also be enabled by default for the proxy at login.

db_user_proxy_clauses

You can enable password-protected roles in a proxy session. Both secure application role and password-protected roles provide a secure method for enabling a role in a session. Oracle recommends using secure password roles instead of password protected roles in instances where the password has to be maintained and transmitted over insecure channels, or if more than one person needs to know the password. Password-protected roles in a proxy session are suitable for situations where automation is used to set the role.

Proxy users can access password-protected roles. Specify the WITH clauses to limit the proxy to some or none of the roles associated with *user*, and the AUTHENTICATION REQUIRED clause to specify whether authentication is required.

WITH ROLE

`WITH ROLE role_name` permits the proxy to connect as the specified user and to activate only the roles that are specified by `role_name`. This clause can contain only roles that are associated with `user`. Password protected roles and secure application roles also need to be listed in the `WITH ROLE` clause if the Proxy user will need to use these secure roles. These secure roles will be included with the `WITH ROLE ALL` clause (the default if `WITH ROLE` is not specified). If `WITH ROLE` doesn't specify the secure roles, then those cannot be enabled even with right password.

WITH ROLE ALL EXCEPT

`WITH ROLE ALL EXCEPT role_name` permits the proxy to connect as the specified user and to activate all roles associated with that user except those specified for `role_name`. This clause can contain only roles that are associated with `user`.

WITH NO ROLES

`WITH NO ROLES` permits the proxy to connect as the specified user, but prohibits the proxy from activating any of that user's roles after connecting, even the secure roles like password protected roles and secure application roles.

AUTHENTICATION REQUIRED

Oracle Database does not expect the proxy to authenticate the user unless you specify the `AUTHENTICATION REQUIRED` clause. This clause ensures that authentication credentials for the user must be presented when the user is authenticated through the specified proxy. The credential is a password.

AUTHENTICATED USING

The `AUTHENTICATED USING` clauses, which appeared in the syntax of earlier releases, have been deprecated and are no longer needed. If you specify the `AUTHENTICATED USING PASSWORD` clause, then Oracle Database converts it to the `AUTHENTICATION REQUIRED` clause. Specifying the `AUTHENTICATED USING CERTIFICATE` clause or the `AUTHENTICATED USING DISTINGUISHED NAME` clause is equivalent to omitting the `AUTHENTICATION REQUIRED` clause.

> **See Also:**
>
> - *Oracle Security Overview* for an overview of database security and for information on middle-tier systems and proxy authentication
> - *Oracle Database Security Guide* for more information on proxies and their use of the database and "Proxy Users: Examples"

Examples

Changing User Identification: Example

The following statement changes the password of the user `sidney` (created in "Creating a Database User: Example") `second_2nd_pwd` and default tablespace to the tablespace `example`:

```
ALTER USER sidney
    IDENTIFIED BY second_2nd_pwd
    DEFAULT TABLESPACE example;
```

The following statement assigns the `new_profile` profile (created in "Creating a Profile: Example") to the sample user `sh`:

```
ALTER USER sh
    PROFILE new_profile;
```

In subsequent sessions, `sh` is restricted by limits in the `new_profile` profile.

The following statement makes all roles granted directly to `sh` default roles, except the `dw_manager` role:

```
ALTER USER sh
    DEFAULT ROLE ALL EXCEPT dw_manager;
```

At the beginning of `sh`'s next session, Oracle Database enables all roles granted directly to `sh` except the `dw_manager` role.

Changing User Authentication: Examples

The following statement changes the authentication mechanism of user `app_user1` (created in "Creating a Database User: Example"):

```
ALTER USER app_user1 IDENTIFIED GLOBALLY AS 'CN=tom,O=oracle,C=US';
```

The following statement causes user `sidney`'s password to expire:

```
ALTER USER sidney PASSWORD EXPIRE;
```

If you cause a database user's password to expire with `PASSWORD EXPIRE`, then the user (or the DBA) must change the password before attempting to log in to the database following the expiration. However, tools such as SQL*Plus allow the user to change the password on the first attempted login following the expiration.

Assigning a Tablespace Group: Example

The following statement assigns `tbs_grp_01` (created in "Adding a Temporary Tablespace to a Tablespace Group: Example") as the tablespace group for user `sh`:

```
ALTER USER sh
  TEMPORARY TABLESPACE tbs_grp_01;
```

Proxy Users: Examples

The following statement alters the user `app_user1`. The example permits the `app_user1` to connect through the proxy user `sh`. The example also allows `app_user1` to enable its `warehouse_user` role (created in "Creating a Role: Example") when connected through the proxy `sh`:

```
ALTER USER app_user1
   GRANT CONNECT THROUGH sh
   WITH ROLE warehouse_user;
```

To show basic syntax, this example uses the sample database Sales History user (`sh`) as the proxy. Normally a proxy user would be an application server or middle-tier entity. For information on creating the interface between an application user and a database by way of an application server, refer to *Oracle Call Interface Programmer's Guide.*

> **See Also:**
>
> - "Creating External Database Users: Examples" to see how to create the `app_user` user
> - "Creating a Role: Example" to see how to create the `dw_user` role

The following statement takes away the right of user `app_user1` to connect through the proxy user `sh`:

```
ALTER USER app_user1 REVOKE CONNECT THROUGH sh;
```

The following hypothetical examples shows another method of proxy authentication:

```
ALTER USER sully GRANT CONNECT THROUGH OAS1
   AUTHENTICATED USING PASSWORD;
```

The following example exposes the user `app_user1` to proxy use by enterprise users. The enterprise users cannot act on behalf of `app_user1` until the Oracle Internet Directory administrator has granted them appropriate privileges:

```
ALTER USER app_user1
   GRANT CONNECT THROUGH ENTERPRISE USERS;
```

ALTER VIEW

Purpose

Use the `ALTER VIEW` statement to explicitly recompile a view that is invalid or to modify view constraints. Explicit recompilation lets you locate recompilation errors before run time. You may want to recompile a view explicitly after altering one of its base tables to ensure that the alteration does not affect the view or other objects that depend on it.

You can also use `ALTER VIEW` to define, modify, or drop view constraints.

You cannot use this statement to change the definition of an existing view. Further, if DDL changes to the view's base tables invalidate the view, then you cannot use this statement to compile the invalid view. In these cases, you must redefine the view using `CREATE VIEW` with the `OR REPLACE` keywords.

When you issue an `ALTER VIEW` statement, Oracle Database recompiles the view regardless of whether it is valid or invalid. The database also invalidates any local objects that depend on the view.

If you alter a view that is referenced by one or more materialized views, then those materialized views are invalidated. Invalid materialized views cannot be used by query rewrite and cannot be refreshed.

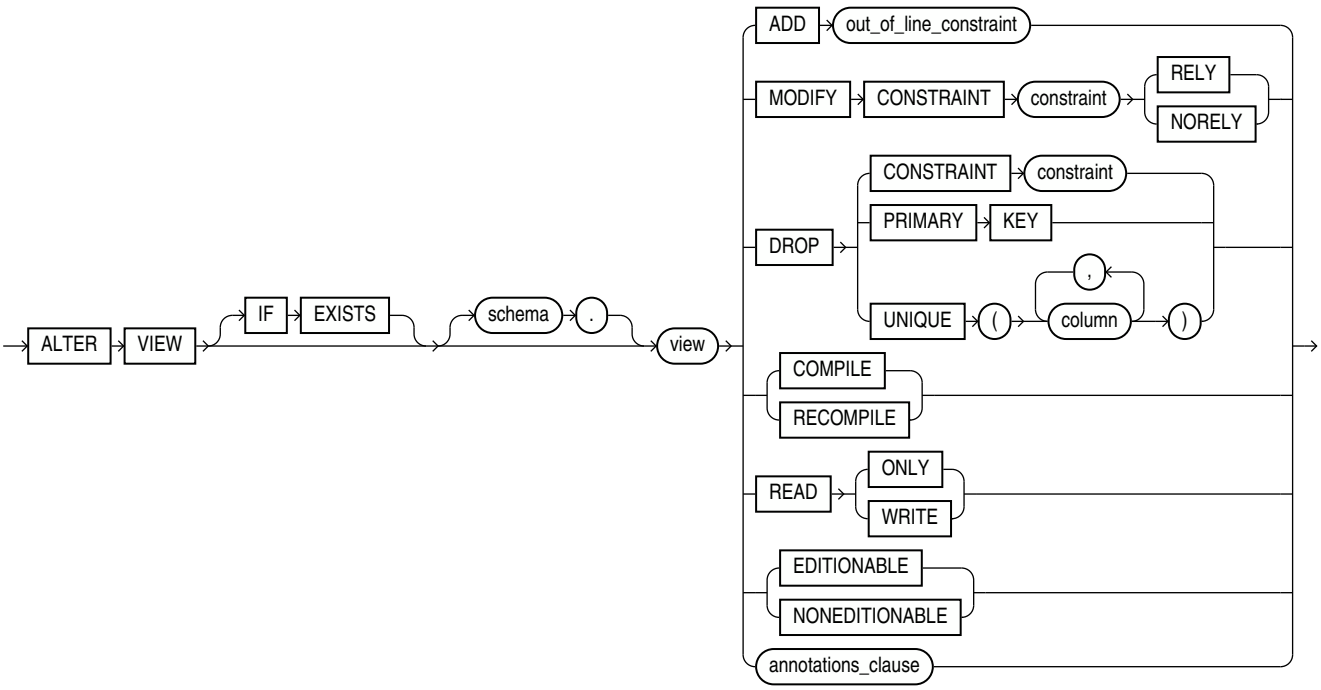
> **See Also:**
>
> - CREATE VIEW for information on redefining a view and ALTER MATERIALIZED VIEW for information on revalidating an invalid materialized view
> - *Oracle Database Data Warehousing Guide* for general information on data warehouses
> - *Oracle Database Concepts* for more about dependencies among schema objects

Prerequisites

The view must be in your own schema or you must have `ALTER ANY TABLE` system privilege.

Syntax

***alter_view*::=**



(*out_of_line_constraint*::=—part of *constraint*::= syntax), *annotations_clause*

Semantics

IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.`

schema

Specify the schema containing the view. If you omit *schema*, then Oracle Database assumes the view is in your own schema.

view

Specify the name of the view to be recompiled.

MODIFY CONSTRAINT Clause

Use the MODIFY CONSTRAINT clause to change the RELY or NORELY setting of an existing view constraint. Refer to "Notes on View Constraints" for general information on view constraints.

Restriction on Modifying Constraints

You cannot change the setting of a unique or primary key constraint if it is part of a referential integrity constraint without dropping the foreign key or changing its setting to match that of *view*.

ADD Clause

Use the ADD clause to add a constraint to *view*. Refer to *constraint* for information on view constraints and their restrictions.

DROP Clause

Use the DROP clause to drop an existing view constraint.

Restriction on Dropping Constraints

You cannot drop a unique or primary key constraint if it is part of a referential integrity constraint on a view.

COMPILE | RECOMPILE

RECOMPILE and COMPILE keywords direct Oracle Database to recompile the view.

Use RECOMPILE to explicitly recompile a view that is invalid or to modify view constraints. Explicit recompilation allows users to locate recompilation errors, before run time.

{ READ ONLY | READ WRITE }

These clauses are valid only for editioning views.

- Specify READ ONLY to indicate that the editioning view cannot be updated.
- Specify READ WRITE to return a read-only editioning view to read/write status.

When you specify these clauses, the database does not invalidate dependent objects, but it may invalidate cursors.

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the view becomes an editioned or noneditioned object if editioning is later enabled for the schema object type VIEW in *schema*. The default is EDITIONABLE. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

> **See Also:**
>
> CREATE VIEW for information about editioning views

annotations_clause

For the full semantics of the annotations clause see *annotations_clause*.

You can only change annotations at the view level with the `ALTER` statement. To drop column-level annotations, you must drop and recreate the view.

Examples

Altering a View: Example

To recompile the view `customer_ro` (created in "Creating a Read-Only View: Example"), issue the following statement:

```
ALTER VIEW customer_ro
    COMPILE;
```

If Oracle Database encounters no compilation errors while recompiling `customer_ro`, then `customer_ro` becomes valid. If recompiling results in compilation errors, then the database returns an error and `customer_ro` remains invalid.

Oracle Database also invalidates all dependent objects. These objects include any procedures, functions, package bodies, and views that reference `customer_ro`. If you subsequently reference one of these objects without first explicitly recompiling it, then the database recompiles it implicitly at run time.

Add and Drop Annotations: Example

The following example drops annotation `Title` from view `MView1` and adds annotation `Identity`:

```
ALTER VIEW HighWageEmp ANNOTATIONS(DROP Title, ADD Identity);
```

ANALYZE

Purpose

Use the `ANALYZE` statement to collect statistics, for example, to:

- Collect or delete statistics about an index or index partition, table or table partition, index-organized table, cluster, or scalar object attribute.
- Validate the structure of an index or index partition, table or table partition, index-organized table, cluster, or object reference (`REF`).
- Identify migrated and chained rows of a table or cluster.

> **Note:**
>
> The use of `ANALYZE` for the collection of optimizer statistics is obsolete.
>
> If you want to collect optimizer statistics, use the `DBMS_STATS` package, which lets you collect statistics in parallel, global statistics for partitioned objects, and helps you fine tune your statistics collection in other ways. See *Oracle Database PL/SQL Packages and Types Reference* for more information on the `DBMS_STATS` package.
>
> Use the `ANALYZE` statement only for the following cases:
>
> - To use the `VALIDATE` or `LIST CHAINED ROWS` clauses
> - To collect information on freelist blocks

Prerequisites

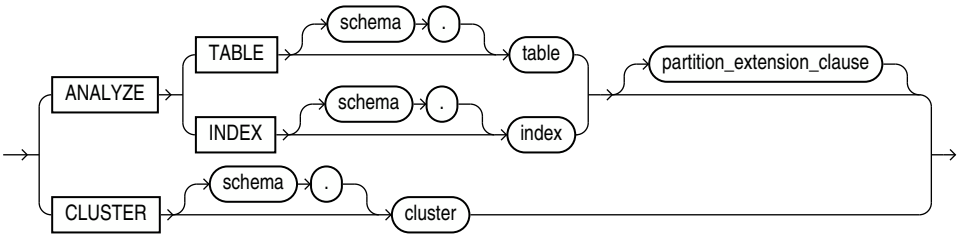
The schema object to be analyzed must be local, and it must be in your own schema or you must have the `ANALYZE ANY` system privilege.

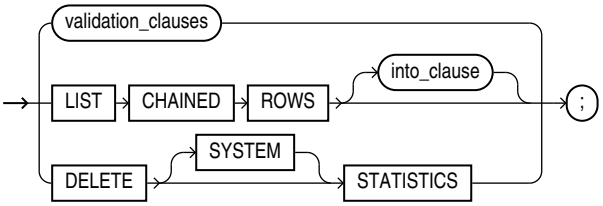
If you want to list chained rows of a table or cluster into a list table, then the list table must be in your own schema, or you must have `INSERT` privilege on the list table, or you must have `INSERT ANY TABLE` system privilege.

If you want to validate a partitioned table, then you must have the `INSERT` object privilege on the table into which you list analyzed rowids, or you must have the `INSERT ANY TABLE` system privilege.

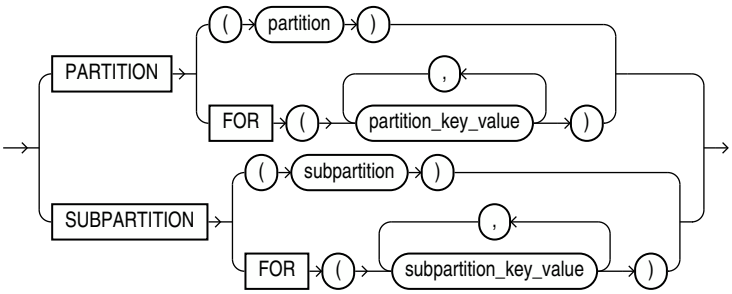
Syntax

***analyze*::=**

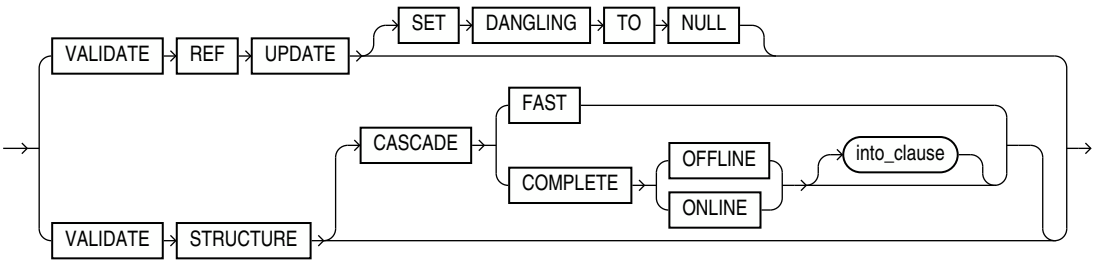




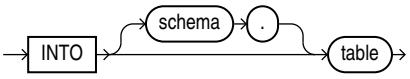
***partition_extension_clause*::=**



***validation_clauses*::=**



***into_clause*::=**



Semantics

schema

Specify the schema containing the table, index, or cluster. If you omit *schema*, then Oracle Database assumes the table, index, or cluster is in your own schema.

TABLE *table*

Specify a table to be analyzed. When you analyze a table, the database collects statistics about expressions occurring in any function-based indexes as well. Therefore, be sure to create function-based indexes on the table before analyzing the table. Refer to CREATE INDEX for more information about function-based indexes.

When analyzing a table, the database skips all domain indexes marked `LOADING` or `FAILED`.

For an index-organized table, the database also analyzes any mapping table and calculates its `PCT_ACCESSS_DIRECT` statistics. These statistics estimate the accuracy of guess data block addresses stored as part of the local rowids in the mapping table.

Oracle Database collects the following statistics for a table. Statistics marked with an asterisk are always computed exactly. Table statistics, including the status of domain indexes, appear in

the data dictionary views USER_TABLES, ALL_TABLES, and DBA_TABLES in the columns shown in parentheses.

- Number of rows (NUM_ROWS)
- * Number of data blocks below the high water mark—the number of data blocks that have been formatted to receive data, regardless whether they currently contain data or are empty (BLOCKS)
- * Number of data blocks allocated to the table that have never been used (EMPTY_BLOCKS)
- Average available free space in each data block in bytes (AVG_SPACE)
- Number of chained rows (CHAIN_COUNT)
- Average row length, including the row overhead, in bytes (AVG_ROW_LEN)

Restrictions on Analyzing Tables

Analyzing tables is subject to the following restrictions:

- You cannot use ANALYZE to collect statistics on data dictionary tables.
- You cannot use ANALYZE to collect statistics on an external table. Instead, you must use the DBMS_STATS package.
- You cannot use ANALYZE to collect default statistics on a temporary table. However, if you have already created an association between one or more columns of a temporary table and a user-defined statistics type, then you can use ANALYZE to collect the user-defined statistics on the temporary table.
- You cannot compute or estimate statistics for the following column types: REF column types, varrays, nested tables, LOB column types (LOB column types are not analyzed, they are skipped), LONG column types, or object types. However, if a statistics type is associated with such a column, then Oracle Database collects user-defined statistics.

> **See Also:**
>
> - ASSOCIATE STATISTICS
> - *Oracle Database Reference* for information on the data dictionary views

partition_extension_clause

partition_extension_clause

Specify the partition or subpartition, or the partition or subpartition value, on which you want statistics to be gathered. You cannot use this clause when analyzing clusters.

If you specify PARTITION and *table* is composite-partitioned, then Oracle Database analyzes all the subpartitions within the specified partition.

INDEX *index*

Specify an index to be analyzed.

Oracle Database collects the following statistics for an index. Statistics marked with an asterisk are always computed exactly. For conventional indexes, when you compute or estimate statistics, the statistics appear in the data dictionary views USER_INDEXES, ALL_INDEXES, and DBA_INDEXES in the columns shown in parentheses.

- * Depth of the index from its root block to its leaf blocks (`BLEVEL`)
- Number of leaf blocks (`LEAF_BLOCKS`)
- Number of distinct index values (`DISTINCT_KEYS`)
- Average number of leaf blocks for each index value (`AVG_LEAF_BLOCKS_PER_KEY`)
- Average number of data blocks for each index value (for an index on a table) (`AVG_DATA_BLOCKS_PER_KEY`)
- Clustering factor (how well ordered the rows are about the indexed values) (`CLUSTERING_FACTOR`)

For domain indexes, this statement invokes the user-defined statistics collection function specified in the statistics type associated with the index (see ASSOCIATE STATISTICS). If no statistics type is associated with the domain index, then the statistics type associated with its indextype is used. If no statistics type exists for either the index or its indextype, then no user-defined statistics are collected. User-defined index statistics appear in the `STATISTICS` column of the data dictionary views `USER_USTATS`, `ALL_USTATS`, and `DBA_USTATS`.

Note:

- When you analyze an index from which a substantial number of rows has been deleted, Oracle Database sometimes executes a `COMPUTE` statistics operation (which can entail a full table scan) even if you request an `ESTIMATE` statistics operation. Such an operation can be quite time consuming.
- In some cases, analyzing an index with the `ANALYZE` statement takes an inordinate amount of time to complete. In these cases, you can use a SQL query to validate the index. If the query determines that there is an inconsistency between a table and the index, then you can use the `ANALYZE` statement for a thorough analysis of the index. Refer to *Oracle Database Administrator's Guide* for more information.

Restriction on Analyzing Indexes

You cannot analyze a domain index that is marked `IN_PROGRESS` or `FAILED`.

See Also:

- CREATE INDEX for more information on domain indexes
- *Oracle Database Reference* for information on the data dictionary views
- "Analyzing an Index: Example"

CLUSTER *cluster*

Specify a cluster to be analyzed. When you collect statistics for a cluster, Oracle Database also automatically collects the statistics for all the tables in the cluster and all their indexes, including the cluster index.

For both indexed and hash clusters, the database collects the average number of data blocks taken up by a single cluster key (`AVG_BLOCKS_PER_KEY`). These statistics appear in the data dictionary views `ALL_CLUSTERS`, `USER_CLUSTERS`, and `DBA_CLUSTERS`.

> **See Also:**
>
> *Oracle Database Reference* for information on the data dictionary views and "Analyzing a Cluster: Example"

validation_clauses

The validation clauses let you validate `REF` values and the structure of the analyzed object.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information about validating tables, indexes, clusters, and materialized views

VALIDATE REF UPDATE Clause

Specify `VALIDATE REF UPDATE` to validate the `REF` values in the specified table, check the rowid portion in each `REF`, compare it with the true rowid, and correct it, if necessary. You can use this clause only when analyzing a table.

If the owner of the table does not have the `READ` or `SELECT` object privilege on the referenced objects, then Oracle Database will consider them invalid and set them to null. Subsequently these `REF` values will not be available in a query, even if it is issued by a user with appropriate privileges on the objects.

SET DANGLING TO NULL

`SET DANGLING TO NULL` sets to null any `REF` values (whether or not scoped) in the specified table that are found to point to an invalid or nonexistent object.

VALIDATE STRUCTURE

Specify `VALIDATE STRUCTURE` to validate the structure of the analyzed object. The statistics collected by this clause are not used by the Oracle Database optimizer.

> **See Also:**
>
> "Validating a Table: Example"

- For a table, Oracle Database verifies the integrity of each of the data blocks and rows. For an index-organized table, the database also generates compression statistics (optimal prefix compression count) for the primary key index on the table.
- For a cluster, Oracle Database automatically validates the structure of the cluster tables.

- For a partitioned table, Oracle Database also verifies that each row belongs to the correct partition. If a row does not collate correctly, then its rowid is inserted into the `INVALID_ROWS` table.
- For a temporary table, Oracle Database validates the structure of the table and its indexes during the current session.
- For an index, Oracle Database verifies the integrity of each data block in the index and checks for block corruption. This clause does not confirm that each row in the table has an index entry or that each index entry points to a row in the table. You can perform these operations by validating the structure of the table with the CASCADE clause.

  Oracle Database also computes compression statistics (optimal prefix compression count) for all normal indexes.

  Oracle Database stores statistics about the index in the data dictionary views `INDEX_STATS` and `INDEX_HISTOGRAM`.

> **See Also:**
>
> *Oracle Database Reference* for information on these views

If Oracle Database encounters corruption in the structure of the object, then an error message is returned. In this case, drop and re-create the object.

CASCADE

Specify `CASCADE` if you want Oracle Database to validate the structure of the indexes associated with the table or cluster. If you use this clause when validating a table, then the database also validates the indexes defined on the table. If you use this clause when validating a cluster, then the database also validates all the cluster tables indexes, including the cluster index.

By default, `CASCADE` performs a `COMPLETE` validation, which can be resource intensive. Specify `FAST` if you want the database to check for the existence of corruptions without reporting details about the corruption. If the `FAST` check finds a corruption, you can then use the `CASCADE` option without the `FAST` clause to locate and learn details about it.

If you use this clause to validate an enabled (but previously disabled) function-based index, then validation errors may result. In this case, you must rebuild the index.

ONLINE | OFFLINE

Specify `ONLINE` to enable Oracle Database to run the validation while DML operations are ongoing within the object. The database reduces the amount of validation performed to allow for concurrency.

> **Note:**
>
> When you validate the structure of an object `ONLINE`, Oracle Database does not collect any statistics, as it does when you validate the structure of the object `OFFLINE`.

Specify `OFFLINE`, to maximize the amount of validation performed. This setting prevents `INSERT`, `UPDATE`, and `DELETE` statements from concurrently accessing the object during validation but allows queries. This is the default.

Restriction on ONLINE

You cannot specify `ONLINE` when analyzing a cluster.

INTO

The `INTO` clause of `VALIDATE STRUCTURE` is valid only for partitioned tables. Specify a table into which Oracle Database lists the rowids of the partitions whose rows do not collate correctly. If you omit *schema*, then the database assumes the list is in your own schema. If you omit this clause altogether, then the database assumes that the table is named `INVALID_ROWS`. The SQL script used to create this table is `UTLVALID.SQL`.

LIST CHAINED ROWS

`LIST CHAINED ROWS` lets you identify migrated and chained rows of the analyzed table or cluster. You cannot use this clause when analyzing an index.

In the `INTO` clause, specify a table into which Oracle Database lists the migrated and chained rows. If you omit *schema*, then the database assumes the chained-rows table is in your own schema. If you omit this clause altogether, then the database assumes that the table is named `CHAINED_ROWS`. The chained-rows table must be on your local database.

You can create the `CHAINED_ROWS` table using one of these scripts:

- `UTLCHAIN.SQL` uses physical rowids. Therefore it can accommodate rows from conventional tables but not from index-organized tables. (See the Note that follows.)
- `UTLCHN1.SQL` uses universal rowids, so it can accommodate rows from both conventional and index-organized tables.

If you create your own chained-rows table, then it must follow the format prescribed by one of these two scripts.

If you are analyzing index-organized tables based on primary keys (rather than universal rowids), then you must create a separate chained-rows table for each index-organized table to accommodate its primary-key storage. Use the SQL scripts `DBMSIOTC.SQL` and `PRVTIOTC.PLB` to define the `BUILD_CHAIN_ROWS_TABLE` procedure, and then execute this procedure to create an `IOT_CHAINED_ROWS` table for each such index-organized table.

> **See Also:**
>
> - The `DBMS_IOT` package in *Oracle Database PL/SQL Packages and Types Reference* for information on the packaged SQL scripts
> - "Listing Chained Rows: Example"

DELETE STATISTICS

Specify `DELETE STATISTICS` to delete any statistics about the analyzed object that are currently stored in the data dictionary. Use this statement when you no longer want Oracle Database to use the statistics.

When you use this clause on a table, the database also automatically removes statistics for all the indexes defined on the table. When you use this clause on a cluster, the database also automatically removes statistics for all the cluster tables and all their indexes, including the cluster index.

Specify `SYSTEM` if you want Oracle Database to delete only system (not user-defined) statistics. If you omit `SYSTEM`, and if user-defined column or index statistics were collected for an object, then the database also removes the user-defined statistics by invoking the statistics deletion function specified in the statistics type that was used to collect the statistics.

> **See Also:**
>
> "Deleting Statistics: Example"

Examples

Deleting Statistics: Example

The following statement deletes statistics about the sample table `oe.orders` and all its indexes from the data dictionary:

```
ANALYZE TABLE orders DELETE STATISTICS;
```

Analyzing an Index: Example

The following statement validates the structure of the sample index `oe.inv_product_ix`:

```
ANALYZE INDEX inv_product_ix VALIDATE STRUCTURE;
```

Validating a Table: Example

The following statement analyzes the sample table `hr.employees` and all of its indexes:

```
ANALYZE TABLE employees VALIDATE STRUCTURE CASCADE;
```

For a table, the `VALIDATE REF UPDATE` clause verifies the `REF` values in the specified table, checks the rowid portion of each `REF`, and then compares it with the true rowid. If the result is an incorrect rowid, then the `REF` is updated so that the rowid portion is correct.

The following statement validates the `REF` values in the sample table `oe.customers`:

```
ANALYZE TABLE customers VALIDATE REF UPDATE;
```

The following statement validates the structure of the sample table `oe.customers` while allowing simultaneous DML:

```
ANALYZE TABLE customers VALIDATE STRUCTURE ONLINE;
```

Analyzing a Cluster: Example

The following statement analyzes the `personnel` cluster (created in "Creating a Cluster: Example"), all of its tables, and all of their indexes, including the cluster index:

```
ANALYZE CLUSTER personnel
    VALIDATE STRUCTURE CASCADE;
```

Listing Chained Rows: Example

The following statement collects information about all the chained rows in the table `orders`:

```
ANALYZE TABLE orders
   LIST CHAINED ROWS INTO chained_rows;
```

The preceding statement places the information into the table `chained_rows`. You can then examine the rows with this query (no rows will be returned if the table contains no chained rows):

```
SELECT owner_name, table_name, head_rowid, analyze_timestamp
    FROM chained_rows
    ORDER BY owner_name, table_name, head_rowid, analyze_timestamp;

OWNER_NAME  TABLE_NAME  HEAD_ROWID         ANALYZE_TIMESTAMP
----------  ----------  ------------------ -----------------
OE          ORDERS      AAAAZzAABAAABrXAAA 25-SEP-2000
```

ASSOCIATE STATISTICS

Purpose

Use the `ASSOCIATE STATISTICS` statement to associate a statistics type (or default statistics) containing functions relevant to statistics collection, selectivity, or cost with one or more columns, standalone functions, packages, types, domain indexes, or indextypes.

For a listing of all current statistics type associations, query the `USER_ASSOCIATIONS` data dictionary view. If you analyze the object with which you are associating statistics, then you can also query the associations in the `USER_USTATS` view.

> **See Also:**
>
> ANALYZE for information on the order of precedence with which `ANALYZE` uses associations

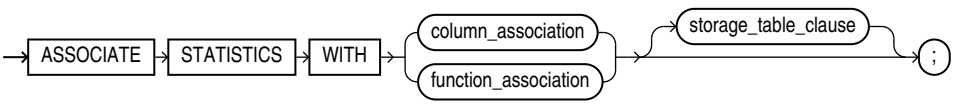
Prerequisites

To issue this statement, you must have the appropriate privileges to alter the base object (table, function, package, type, domain index, or indextype). In addition, unless you are associating only default statistics, you must have execute privilege on the statistics type. The statistics type must already have been defined.

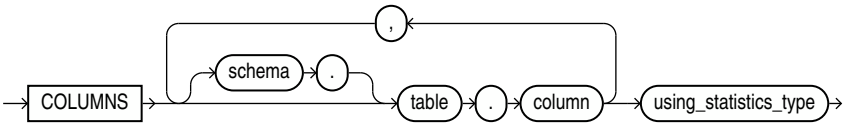
> **See Also:**
>
> CREATE TYPE for information on defining types

Syntax

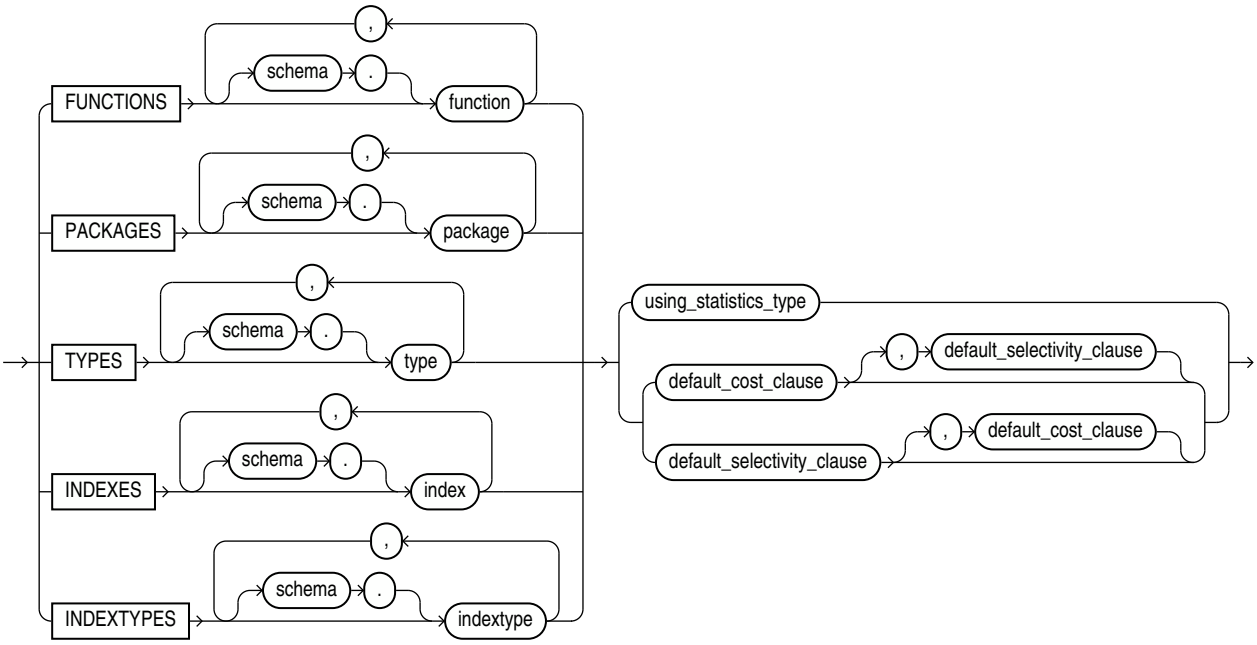
***associate_statistics*::=**



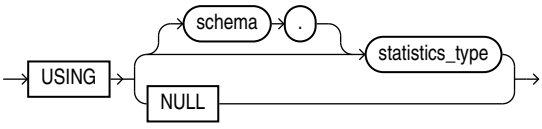
***column_association*::=**



***function_association*::=**



***using_statistics_type*::=**



***default_cost_clause*::=**

***default_selectivity_clause*::=**

***storage_table_clause*::=**

Semantics

column_association

Specify one or more table columns. If you do not specify *schema*, then Oracle Database assumes the table is in your own schema.

function_association

Specify one or more standalone functions, packages, user-defined data types, domain indexes, or indextypes. If you do not specify *schema*, then Oracle Database assumes the object is in your own schema.

- `FUNCTIONS` refers only to standalone functions, not to method types or to built-in functions.
- `TYPES` refers only to user-defined types, not to built-in SQL data types.

Restriction on *function_association*

You cannot specify an object for which you have already defined an association. You must first disassociate the statistics from this object.

> **See Also:**
>
> DISASSOCIATE STATISTICS "Associating Statistics: Example"

using_statistics_type

Specify the statistics type (or a synonym for the type) being associated with column, function, package, type, domain index, or indextype. The *statistics_type* must already have been created.

The `NULL` keyword is valid only when you are associating statistics with a column or an index. When you associate a statistics type with an object type, columns of that object type inherit the statistics type. Likewise, when you associate a statistics type with an indextype, index instances of the indextype inherit the statistics type.You can override this inheritance by associating a different statistics type for the column or index. Alternatively, if you do not want to associate any statistics type for the column or index, then you can specify `NULL` in the *using_statistics_type* clause.

Restriction on Specifying Statistics Type

You cannot specify `NULL` for functions, packages, types, or indextypes.

> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide* for information on creating statistics collection functions

default_cost_clause

Specify default costs for standalone functions, packages, types, domain indexes, or indextypes. If you specify this clause, then you must include one number each for CPU cost, I/O cost, and network cost, in that order. Each cost is for a single execution of the function or method or for a single domain index access. Accepted values are integers of zero or greater.

default_selectivity_clause

Specify as a percent the default selectivity for predicates with standalone functions, types, packages, or user-defined operators. The *default_selectivity_clause* must be a number between 0 and 100. Values outside this range are ignored.

Restriction on the *default_selectivity_clause*

You cannot specify `DEFAULT SELECTIVITY` for domain indexes or indextypes.

> **See Also:**
>
> "Specifying Default Cost: Example"

storage_table_clause

This clause is relevant only for statistics on `INDEXTYPE`.

- Specify `WITH SYSTEM MANAGED STORAGE TABLES` to indicate that the storage of statistics data is to be managed by the system. The type you specify in *statistics_type* should be storing the statistics related information in tables that are maintained by the system. Also, the indextype you specify must already have been created or altered to support the `WITH SYSTEM MANAGED STORAGE TABLES` clause.
- Specify `WITH USER MANAGED STORAGE TABLES` to indicate that the tables that store the user-defined statistics will be managed by the user. This is the default behavior.

Examples

Associating Statistics: Example

This statement creates an association for the standalone package `emp_mgmt`. See *Oracle Database PL/SQL Language Reference* for the example that creates this package.

```
ASSOCIATE STATISTICS WITH PACKAGES emp_mgmt DEFAULT SELECTIVITY 10;
```

Specifying Default Cost: Example

This statement specifies that using the domain index `salary_index`, created in "Using Extensible Indexing ", to implement a given predicate always has a CPU cost of 100, I/O cost of 5, and network cost of 0.

```
ASSOCIATE STATISTICS WITH INDEXES salary_index DEFAULT COST (100,5,0);
```

The optimizer will use these default costs instead of calling a cost function.

AUDIT (Traditional Auditing)

> **Note:**
>
> Traditional Auditing is desupported in Oracle Database Release 23. Oracle recommends that you use unified auditing instead.

AUDIT (Unified Auditing)

This section describes the `AUDIT` statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12*c* and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

Purpose

Use the `AUDIT` statement to:

- Enable a unified audit policy for all users or for specified users
- Specify whether an audit record is created if the audited event fails, succeeds, or both
- Specify application context attributes, whose values will be recorded in audit records

Changes made to the audit policy become effective immediately in the current session and in all active sessions without re-login.

> **See Also:**
>
> - NOAUDIT (Unified Auditing)
> - CREATE AUDIT POLICY (Unified Auditing)
> - ALTER AUDIT POLICY (Unified Auditing)
> - DROP AUDIT POLICY (Unified Auditing)

Prerequisites

You must have the `AUDIT SYSTEM` system privilege or the `AUDIT_ADMIN` role.

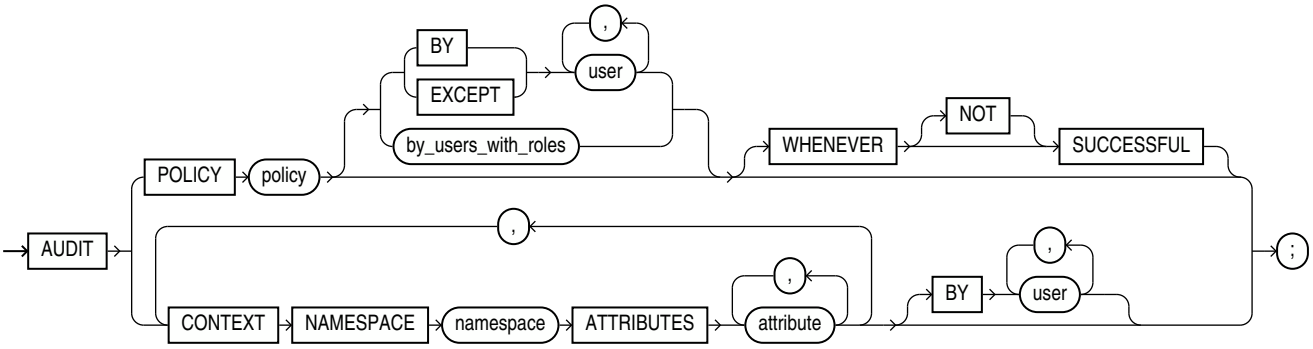
If you are connected to a multitenant container database (CDB), then to enable a common unified audit policy, the current container must be the root and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role. To enable a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role, or you must have the locally granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` local role in the container.

To specify the `AUDIT CONTEXT` ... statement when connected to a CDB, you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role, or you must have

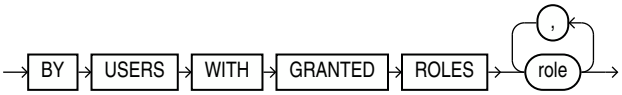
the locally granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` local role in the current session's container.

Syntax

***unified_audit*::=**



***by_users_with_roles*::=**



Semantics

policy

With Oracle Database Release 21c unified audit policies are enforced on the current user who executes the SQL statement.

Specify the name of the unified audit policy to be enabled. (The policy must be created previously by the `CREATE AUDIT POLICY` statement.) The policy becomes active immediately for the current session and active ongoing sessions as soon as the `AUDIT POLICY` statement is executed.

You can find descriptions of all unified audit policies by querying the `AUDIT_UNIFIED_POLICIES` view and descriptions of all *enabled* unified audit policies by querying the `AUDIT_UNIFIED_ENABLED_POLICIES` view.

When you enable a unified audit policy, all SQL statements and operations that satisfy either a system privilege or action or role audit option specified in the enabled policy will be audited—that is, a unified audit record will be created in the `UNIFIED_AUDIT_TRAIL` view. If a single SQL statement or operation satisfies multiple enabled policies, then only one unified audit record will be created and all satisfied audit policy names will appear in a comma-separated list in the `UNIFIED_AUDIT_POLICIES` column of the `UNIFIED_AUDIT_TRAIL` view.

> **See Also:**
>
> - CREATE AUDIT POLICY (Unified Auditing)
> - *Oracle Database Reference* for more information on the `AUDIT_UNIFIED_POLICIES`, `AUDIT_UNIFIED_ENABLED_POLICIES`, and `UNIFIED_AUDIT_TRAIL` views

BY | EXCEPT

Specify the `BY` clause to enable *`policy`* for only the specified users.

Specify the `EXCEPT` clause to enable *`policy`* for all users except the specified users.

If you omit the `BY` and `EXCEPT` clauses and the *`by_users_with_roles`* clause, then Oracle Database enables *`policy`* for all users.

If *`policy`* is a common unified audit policy, then *`user`* must be a common user. If *`policy`* is a local unified audit policy, then *`user`* must be a common user or a local user in the container to which you are connected.

Notes on the BY and EXCEPT Clauses

The following notes apply to the `BY` and `EXCEPT` clauses:

- If multiple `AUDIT ... BY ...` statements are specified for the same unified audit policy, then the policy is enabled for the union of the users specified in each statement.
- If multiple `AUDIT ... EXCEPT ...` statements are specified for the same unified audit policy, then only the most recently specified statement takes effect. That is, the policy is enabled for all users except the users specified in the most recent `AUDIT ... EXCEPT ...` statement.
- If a policy is enabled using the `BY` clause and you would like to instead enable it using the `EXCEPT` clause, then you must first use the `NOAUDIT ... BY ...` statement to disable the policy for all users for whom the policy is currently enabled, and then enable the policy with the `AUDIT ... EXCEPT ...` statement.
- If a policy is enabled using the `EXCEPT` clause and you would like to instead enable it using the `BY` clause, then you must first use the `NOAUDIT` statement to disable the audit policy. Note that you cannot specify the `EXCEPT` clause with the `NOAUDIT` statement. You can then enable the policy with the `AUDIT ... BY ...` statement.

Restriction on the BY and EXCEPT Clauses

You cannot specify an `AUDIT ... BY ...` statement and an `AUDIT ... EXCEPT ...` statement for the same unified audit policy. If you attempt to do so, then an error occurs.

by_users_with_roles

Specify this clause to enable *`policy`* for users who have been directly or indirectly granted the specified roles. If you subsequently grant one of the roles to an additional user or to a role which is directly or indirectly granted to a user, then the policy automatically applies to that user. If you subsequently revoke one of the roles from a user or from a role which was directly or indirectly granted to a role or a user, then the policy no longer applies to that user.

When you are connected to a CDB, if *`policy`* is a common unified audit policy, then *`role`* must be a common role. If *`policy`* is a local unified audit policy, then *`role`* must be a common role or a local role in the container to which you are connected.

Enabling a Local Audit Policy on Roles

Local audit policy can be enabled on local roles as well as on common roles. When a local audit policy is enabled on a common role, it generates audit records when a common role is granted to user locally or commonly in the container.

Enabling a Common Audit Policy on Roles

Common audit policy can only be enabled on common roles. When a common audit policy is enabled on a common role, it generates audit records when a common role is granted to an user commonly or locally in the ROOT container.

WHENEVER [NOT] SUCCESSFUL

Specify `WHENEVER SUCCESSFUL` to audit only SQL statements and operations that succeed.

Specify `WHENEVER NOT SUCCESSFUL` to audit only SQL statements and operations that fail or result in errors.

If you omit this clause, then Oracle Database performs the audit regardless of success or failure.

CONTEXT Clause

Specify the `CONTEXT` clause to include the values of context attributes in audit records.

- For *`namespace`*, specify the context namespace.
- For *`attribute`*, specify one or more context attributes whose values you want to include in audit records.
- Use the optional `BY` *`user`* clause to include the values of the context attributes only in audit records for events executed by the specified users. If you omit the `BY` clause, then the values of the context attributes are included in all audit records.

If you specify the `CONTEXT` clause when the current container is the root of a CDB, then the values of context attributes will be included in audit records only for events executed in the root. If you specify the optional `BY` clause, then *`user`* must be a common user.

If you specify the `CONTEXT` clause when the current container is a pluggable database (PDB), then the values of context attributes will be included in audit records only for events executed in that PDB. If you specify the optional `BY` clause, then *`user`* must be a common user or a local user in that PDB.

You can find the application context attributes that are configured to be captured in the audit trail by querying the `AUDIT_UNIFIED_CONTEXTS` view.

> **See Also:**
>
> *Oracle Database Reference* for more information on the `AUDIT_UNIFIED_CONTEXTS` view

Examples

The following examples enable unified audit policies that were created in the `CREATE AUDIT POLICY` "Examples".

Enabling a Unified Audit Policy for All Users: Example

The following statement enables unified audit policy `table_pol` for all users:

```
AUDIT POLICY table_pol;
```

The following statement verifies that `table_pol` is enabled for all users:

```
SELECT policy_name, enabled_option, entity_name
  FROM audit_unified_enabled_policies
  WHERE policy_name = 'TABLE_POL';

POLICY_NAME  ENABLED_OPTION  ENTITY_NAME
-----------  -----------  ---------
TABLE_POL    BY           ALL USERS
```

Enabling a Unified Audit Policy for Specific Users: Examples

The following statement enables unified audit policy `dml_pol` for only users `hr` and `sh`:

```
AUDIT POLICY dml_pol BY hr, sh;
```

The following statement verifies that `dml_pol` is enabled for only users `hr` and `sh`:

```
SELECT policy_name, enabled_option, entity_name
  FROM audit_unified_enabled_policies
  WHERE policy_name = 'DML_POL'
  ORDER BY entity_name;

POLICY_NAME  ENABLED_OPTION  ENTITY_NAME
-----------  -----------  ---------
DML_POL      BY           HR
DML_POL      BY           SH
```

The following statement enables unified audit policy `read_dir_pol` for all users except `hr`:

```
AUDIT POLICY read_dir_pol EXCEPT hr;
```

The following statement verifies that `read_dir_pol` is enabled for all users except `hr`:

```
SELECT policy_name, enabled_option, entity_name
  FROM audit_unified_enabled_policies
  WHERE policy_name = 'READ_DIR_POL';

POLICY_NAME   ENABLED_OPTION  ENTITY_NAME
------------  -----------  ---------
READ_DIR_POL  EXCEPT       HR
```

The following statement enables unified audit policy `security_pol` for user `hr` and audits only the SQL statements and operations that fail:

```
AUDIT POLICY security_pol BY hr WHENEVER NOT SUCCESSFUL;
```

The following statement verifies that `security_pol` is enabled for only user `hr` and that only the SQL statements and operations that fail will be audited:

```
SELECT policy_name, enabled_option, entity_name, success, failure
  FROM audit_unified_enabled_policies
  WHERE policy_name = 'SECURITY_POL';

POLICY_NAME   ENABLED_OPTION           ENTITY_NAME   SUCCESS  FAILURE
------------  --------------------  ----------  -------  -------
SECURITY_POL  BY                    HR          NO       YES
```

Including Values of Context Attributes in Audit Records: Example

The following statement instructs the database to include the values of namespace `USERENV` attributes `CURRENT_USER` and `DB_NAME` in all audit records for user `hr`:

```
AUDIT CONTEXT NAMESPACE userenv
  ATTRIBUTES current_user, db_name
  BY hr;
```

CALL

Purpose

Use the `CALL` statement to execute a **routine** (a standalone procedure or function, or a procedure or function defined within a type or package) from within SQL.

> **Note:**
>
> The restrictions on user-defined function expressions specified in "Function Expressions " apply to the `CALL` statement as well.

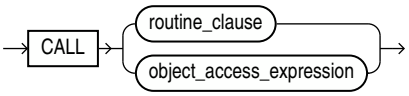
> **See Also:**
>
> *Oracle Database PL/SQL Language Reference* for information on creating such routine

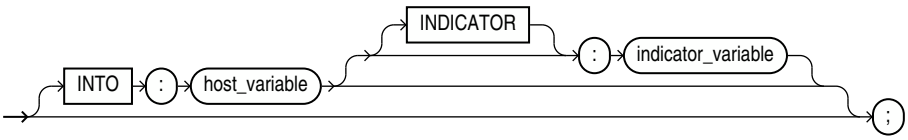
Prerequisites

You must have `EXECUTE` privilege on the standalone routine or on the type or package in which the routine is defined.

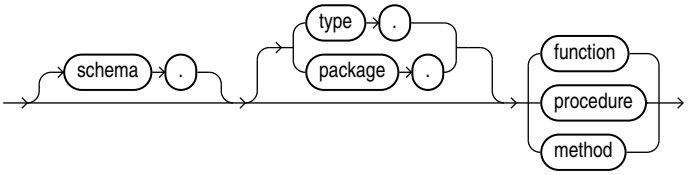
Syntax

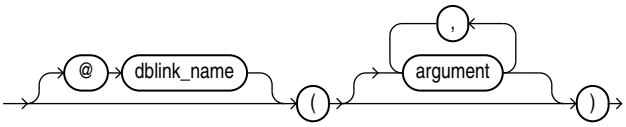
***call*::=**



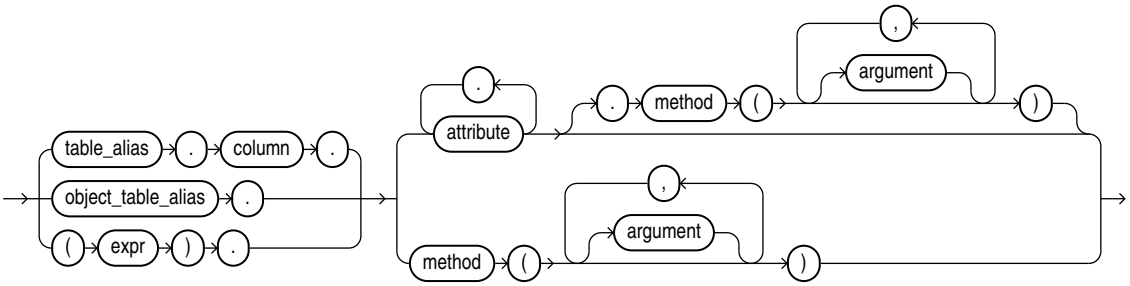


***routine_clause*::=**





***object_access_expression*::=**



Semantics

You can execute a routine in two ways. You can issue a call to the routine itself by name, by using the *routine_clause*, or you can invoke a routine inside the type of an expression, by using an *object_access_expression*.

routine_clause

Specify the name of the function or procedure being called, or a synonym that resolves to a function or procedure.

When you call a member function or procedure of a type, if the first argument (`SELF`) is a null `IN OUT` argument, then Oracle Database returns an error. If `SELF` is a null `IN` argument, then the database returns null. In both cases, the function or procedure is not invoked.

Restriction on Functions

If the routine is a function, then the `INTO` clause is required.

schema

Specify the schema in which the standalone routine, or the package or type containing the routine, resides. If you do not specify *schema*, then Oracle Database assumes the routine is in your own schema.

type* or *package

Specify the type or package in which the routine is defined.

@dblink

In a distributed database system, specify the name of the database containing the standalone routine, or the package or function containing the routine. If you omit *dblink*, then Oracle Database looks in your local database.

> **See Also:**
>
> "Calling a Procedure: Example" for an example of calling a routine directly

object_access_expression

If you have an expression of an object type, such as a type constructor or a bind variable, then you can use this form of expression to call a routine defined within the type. In this context, the *object_access_expression* is limited to method invocations.

> **See Also:**
>
> "Object Access Expressions " for syntax and semantics of this form of expression, and "Calling a Procedure Using an Expression of an Object Type: Example" for an example of calling a routine using an expression of an object type

argument

Specify one or more arguments to the routine, if the routine takes arguments. You can use positional, named, or mixed notation for *argument*. For example, all of the following notations are correct:

```
CALL my_procedure(arg1 => 3, arg2 => 4)

CALL my_procedure(3, 4)

CALL my_procedure(3, arg2 => 4)
```

Restrictions on Applying Arguments to Routines

The *argument* is subject to the following restrictions:

- The data types of the parameters passed by the `CALL` statement must be SQL data types. They cannot be PL/SQL-only data types such as `BOOLEAN`.
- An *argument* cannot be a pseudocolumn or either of the object reference functions `VALUE` or `REF`.
- Any *argument* that is an `IN OUT` or `OUT` argument of the routine must correspond to a host variable expression.
- The number of arguments, including any return argument, is limited to 1000.
- You cannot bind arguments of character and raw data types (`CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `RAW`, `LONG RAW`) that are larger than 4K.

INTO :*host_variable*

The `INTO` clause applies only to calls to functions. Specify which host variable will store the return value of the function.

:*indicator_variable*

Specify the value or condition of the host variable.

> **See Also:**
>
> *Pro*C/C++ Programmer's Guide* for more information on host variables and indicator variables

Examples

Calling a Procedure: Example

The following statement removes the Entertainment department (created in "Inserting Sequence Values: Example") using uses the `remove_dept` procedure. See *Oracle Database PL/SQL Language Reference* for the example that creates this procedure.

```
CALL emp_mgmt.remove_dept(162);
```

Calling a Procedure Using an Expression of an Object Type: Example

The following examples show how call a procedure by using an expression of an object type in the `CALL` statement. The example uses the `warehouse_typ` object type in the order entry sample schema `OE`:

```
ALTER TYPE warehouse_typ
      ADD MEMBER FUNCTION ret_name
      RETURN VARCHAR2
      CASCADE;

CREATE OR REPLACE TYPE BODY warehouse_typ
      AS MEMBER FUNCTION ret_name
      RETURN VARCHAR2
      IS
         BEGIN
            RETURN self.warehouse_name;
         END;
      END;
/
VARIABLE x VARCHAR2(25);

CALL warehouse_typ(456, 'Warehouse 456', 2236).ret_name()
   INTO :x;

PRINT x;
X
--------------------------------
Warehouse 456
```

The next example shows how to use an external function to achieve the same thing:

```
CREATE OR REPLACE FUNCTION ret_warehouse_typ(x warehouse_typ)
  RETURN warehouse_typ
```

```
  IS
    BEGIN
      RETURN x;
    END;
/
CALL ret_warehouse_typ(warehouse_typ(234, 'Warehouse 234',
   2235)).ret_name()
   INTO :x;

PRINT x;

X
--------------------------------
Warehouse 234
```

COMMENT

Purpose

Use the `COMMENT` statement to add to the data dictionary a comment about a table or table column, unified audit policy, edition, indextype, materialized view, mining model, operator, or view.

To drop a comment from the database, set it to the empty string ' '.

> **See Also:**
>
> - "Comments " for more information on associating comments with SQL statements and schema objects
> - *Oracle Database Reference* for information on the data dictionary views that display comments

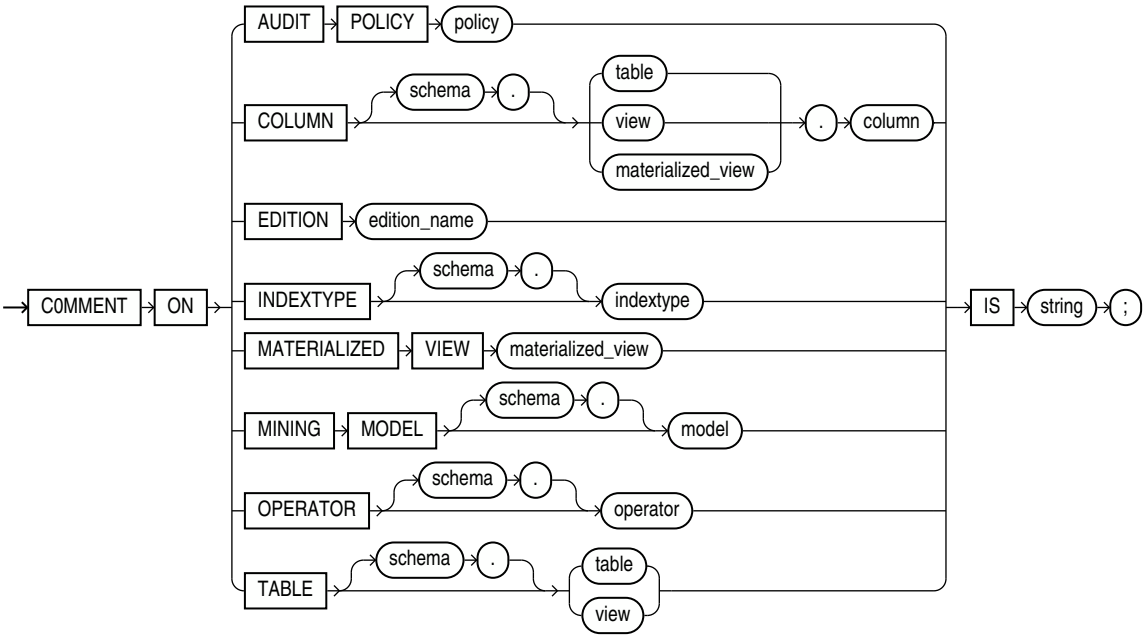
Prerequisites

The object about which you are adding a comment must be in your own schema or:

- To add a comment to a table, view, or materialized view, you must have `COMMENT ANY TABLE` system privilege.
- To add a comment to a unified audit policy, you must have the `AUDIT SYSTEM` system privilege or the `AUDIT_ADMIN` role.
- To add a comment to an edition, you must have the `CREATE ANY EDITION` system privilege, granted either directly or through a role.
- To add a comment to an indextype, you must have the `CREATE ANY INDEXTYPE` system privilege.
- To add a comment to a mining model, you must have the `COMMENT ANY MINING MODEL` system privilege.
- To add a comment to an operator, you must have the `CREATE ANY OPERATOR` system privilege.

Syntax

***comment*::=**



Semantics

AUDIT POLICY Clause

Specify the name of the unified audit policy to be commented.

You can view the comments on a particular unified audit policy by querying the `AUDIT_UNIFIED_POLICY_COMMENTS` data dictionary view.

COLUMN Clause

Specify the name of the column of a table, view, or materialized view to be commented. If you omit *`schema`*, then Oracle Database assumes the table, view, or materialized view is in your own schema.

You can view the comments on a particular table or column by querying the data dictionary views `USER_TAB_COMMENTS`, `DBA_TAB_COMMENTS`, or `ALL_TAB_COMMENTS` or `USER_COL_COMMENTS`, `DBA_COL_COMMENTS`, or `ALL_COL_COMMENTS`.

EDITION Clause

Specify the name of an existing edition to be commented.

You can query the data dictionary view `ALL_EDITION_COMMENTS` to view comments associated with editions that are accessible to the current user. You can query `DBA_EDITION_COMMENTS` to view comments associated with all editions in the database.

TABLE Clause

Specify the schema and name of the table or materialized view to be commented. If you omit *`schema`*, then Oracle Database assumes the table or materialized view is in your own schema.

> **Note:**
>
> In earlier releases, you could use this clause to create a comment on a materialized view. You should now use the `COMMENT ON MATERIALIZED VIEW` clause for materialized views.

INDEXTYPE Clause

Specify the name of the indextype to be commented. If you omit *schema*, then Oracle Database assumes the indextype is in your own schema.

You can view the comments on a particular indextype by querying the data dictionary views `USER_INDEXTYPE_COMMENTS`, `DBA_INDEXTYPE_COMMENTS`, or `ALL_INDEXTYPE_COMMENTS`.

MATERIALIZED VIEW Clause

Specify the name of the materialized view to be commented. If you omit *schema*, then Oracle Database assumes the materialized view is in your own schema.

You can view the comments on a particular materialized view by querying the data dictionary views `USER_MVIEW_COMMENTS`, `DBA_MVIEW_COMMENTS`, or `ALL_MVIEW_COMMENTS`.

MINING MODEL

Specify the name of the mining model to be commented.

You can view the comments on a particular mining model by querying the `COMMENTS` column of the data dictionary views `USER_MINING_MODELS`, `DBA_MINING_MODELS`, or `ALL_MINING_MODELS`.

OPERATOR Clause

Specify the name of the operator to be commented. If you omit *schema*, then Oracle Database assumes the operator is in your own schema.

You can view the comments on a particular operator by querying the data dictionary views `USER_OPERATOR_COMMENTS`, `DBA_OPERATOR_COMMENTS`, or `ALL_OPERATOR_COMMENTS`.

IS '*string*'

Specify the text of the comment. Refer to "Text Literals " for a syntax description of *'string'*.

Examples

Creating Comments: Example

To insert an explanatory remark on the `job_id` column of the `employees` table, you might issue the following statement:

```
COMMENT ON COLUMN employees.job_id
   IS 'abbreviated job title';
```

To drop this comment from the database, issue the following statement:

```
COMMENT ON COLUMN employees.job_id IS '';
```

13

SQL Statements: COMMIT to CREATE JSON RELATIONAL DUALITY VIEW

This chapter contains the following SQL statements:

- COMMIT
- CREATE ANALYTIC VIEW
- CREATE ATTRIBUTE DIMENSION
- CREATE AUDIT POLICY (Unified Auditing)
- CREATE CLUSTER
- CREATE CONTEXT
- CREATE CONTROLFILE
- CREATE DATABASE
- CREATE DATABASE LINK
- CREATE DIMENSION
- CREATE DIRECTORY
- CREATE DISKGROUP
- CREATE DOMAIN
- CREATE EDITION
- CREATE FLASHBACK ARCHIVE
- CREATE FUNCTION
- CREATE HIERARCHY
- CREATE INDEX
- CREATE INDEXTYPE
- CREATE INMEMORY JOIN GROUP
- CREATE JAVA
- CREATE JSON RELATIONAL DUALITY VIEW

COMMIT

Purpose

Use the `COMMIT` statement to end your current transaction and make permanent all changes performed in the transaction. A **transaction** is a sequence of SQL statements that Oracle Database treats as a single unit. This statement also erases all savepoints in the transaction and releases transaction locks.

Until you commit a transaction:

- You can see any changes you have made during the transaction by querying the modified tables, but other users cannot see the changes. After you commit the transaction, the changes are visible to other users' statements that execute after the commit.
- You can roll back (undo) any changes made during the transaction with the `ROLLBACK` statement (see ROLLBACK).

Oracle Database issues an implicit `COMMIT` under the following circumstances:

- Before any syntactically valid data definition language (DDL) statement, even if the statement results in an error
- After any data definition language (DDL) statement that completes without an error

You can also use this statement to:

- Commit an in-doubt distributed transaction manually
- Terminate a read-only transaction begun by a `SET TRANSACTION` statement

Oracle recommends that you explicitly end every transaction in your application programs with a `COMMIT` or `ROLLBACK` statement, including the last transaction, before disconnecting from Oracle Database. If you do not explicitly commit the transaction and the program terminates abnormally, then the last uncommitted transaction is automatically rolled back.

A normal exit from most Oracle utilities and tools causes the current transaction to be committed. A normal exit from an Oracle precompiler program does not commit the transaction and relies on Oracle Database to roll back the current transaction.

> **See Also:**
>
> - *Oracle Database Concepts* for more information on transactions
> - SET TRANSACTION for more information on specifying characteristics of a transaction

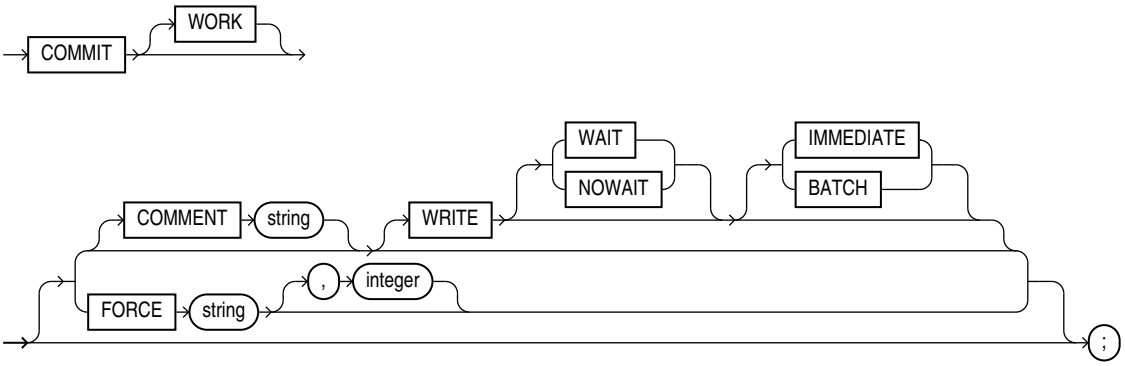
Prerequisites

You need no privileges to commit your current transaction.

To manually commit a distributed in-doubt transaction that you originally committed, you must have `FORCE TRANSACTION` system privilege. To manually commit a distributed in-doubt transaction that was originally committed by another user, you must have `FORCE ANY TRANSACTION` system privilege.

Syntax

***commit*::=**



Semantics

COMMIT

All clauses after the `COMMIT` keyword are optional. If you specify only `COMMIT`, then the default is `COMMIT WORK WRITE WAIT IMMEDIATE`.

WORK

The `WORK` keyword is supported for compliance with standard SQL. The statements `COMMIT` and `COMMIT WORK` are equivalent.

COMMENT Clause

This clause is supported for backward compatibility. Oracle recommends that you use named transactions instead of commit comments.

> **See Also:**
>
> SET TRANSACTION and *Oracle Database Concepts* for more information on named transactions

Specify a comment to be associated with the current transaction. The '*text*' is a quoted literal of up to 255 bytes that Oracle Database stores in the data dictionary view `DBA_2PC_PENDING` along with the transaction ID if a distributed transaction becomes in doubt. This comment can help you diagnose the failure of a distributed transaction.

> **See Also:**
>
> COMMENT for more information on adding comments to SQL statements

WRITE Clause

Use this clause to specify the priority with which the redo information generated by the commit operation is written to the redo log. This clause can improve performance by reducing latency, thus eliminating the wait for an I/O to the redo log. Use this clause to improve response time in environments with stringent response time requirements where the following conditions apply:

- The volume of update transactions is large, requiring that the redo log be written to disk frequently.
- The application can tolerate the loss of an asynchronously committed transaction.
- The latency contributed by waiting for the redo log write to occur contributes significantly to overall response time.

You can specify the `WAIT` | `NOWAIT` and `IMMEDIATE` | `BATCH` clauses in any order.

> **Note:**
>
> If you omit this clause, then the behavior of the commit operation is controlled by the `COMMIT_LOGGING` and `COMMIT_WAIT` initialization parameters, if they have been set.

WAIT | NOWAIT

Use these clauses to specify when control returns to the user.

- The `WAIT` parameter ensures that the commit will return only after the corresponding redo is persistent in the online redo log. Whether in `BATCH` or `IMMEDIATE` mode, when the client receives a successful return from this `COMMIT` statement, the transaction has been committed to durable media. A crash occurring after a successful write to the log can prevent the success message from returning to the client. In this case the client cannot tell whether or not the transaction committed.
- The `NOWAIT` parameter causes the commit to return to the client whether or not the write to the redo log has completed. This behavior can increase transaction throughput. With the `WAIT` parameter, if the commit message is received, then you can be sure that no data has been lost.

> **Note:**
>
> With `NOWAIT`, a crash occurring after the commit message is received, but before the redo log record(s) are written, can falsely indicate to a transaction that its changes are persistent.

If you omit this clause, then the transaction commits with the `WAIT` behavior.

IMMEDIATE | BATCH

Use these clauses to specify when the redo is written to the log.

- The `IMMEDIATE` parameter causes the log writer process (LGWR) to write the transaction's redo information to the log. This operation option forces a disk I/O, so it can reduce transaction throughput.

- The `BATCH` parameter causes the redo to be buffered to the redo log, along with other concurrently executing transactions. When sufficient redo information is collected, a disk write of the redo log is initiated. This behavior is called "group commit", as redo for multiple transactions is written to the log in a single I/O operation.

If you omit this clause, then the transaction commits with the `IMMEDIATE` behavior.

> **See Also:**
>
> *Oracle Database Concepts* for more information on asynchronous commit

FORCE Clause

In a distributed database system, the `FORCE` *`string`* [, *`integer`*] clause lets you manually commit an in-doubt distributed transaction. The transaction is identified by the '*`string`*' containing its local or global transaction ID. To find the IDs of such transactions, query the data dictionary view `DBA_2PC_PENDING`. You can use *`integer`* to specifically assign the transaction a system change number (SCN). If you omit *`integer`*, then the transaction is committed using the current SCN.

> **Note:**
>
> A `COMMIT` statement with a `FORCE` clause commits only the specified transactions. Such a statement does not affect your current transaction.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information on these topics

Examples

Committing an Insert: Example

This statement inserts a row into the `hr.regions` table and commits this change:

```
INSERT INTO regions VALUES (5, 'Antarctica');

COMMIT WORK;
```

To commit the same insert operation and instruct the database to buffer the change to the redo log, without initiating disk I/O, use the following `COMMIT` statement:

```
COMMIT WRITE BATCH;
```

Commenting on COMMIT: Example

The following statement commits the current transaction and associates a comment with it:

```
COMMIT
    COMMENT 'In-doubt transaction Code 36, Call (415) 555-2637';
```

If a network or machine failure prevents this distributed transaction from committing properly, then Oracle Database stores the comment in the data dictionary along with the transaction ID. The comment indicates the part of the application in which the failure occurred and provides information for contacting the administrator of the database where the transaction was committed.

Forcing an In-Doubt Transaction: Example

The following statement manually commits a hypothetical in-doubt distributed transaction. Query the `V$CORRUPT_XID_LIST` data dictionary view to find the transaction IDs of corrupt transactions. You must have DBA privileges to view the `V$CORRUPT_XID_LIST` and to issue this statement.

```
COMMIT FORCE '22.57.53';
```

CREATE ANALYTIC VIEW

Purpose

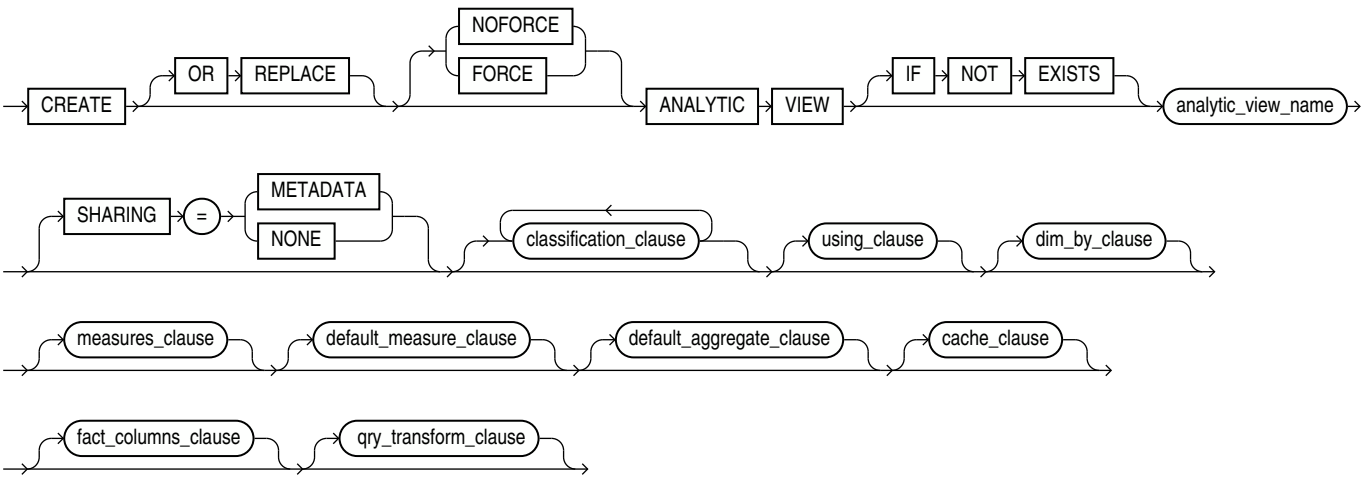
Use the `CREATE ANALYTIC VIEW` statement to create an analytic view. An analytic view specifies the source of its fact data and defines measures that describe calculations or other analytic operations to perform on the data. An analytic view also specifies the attribute dimensions and hierarchies that define the rows of the analytic view.

Prerequisites

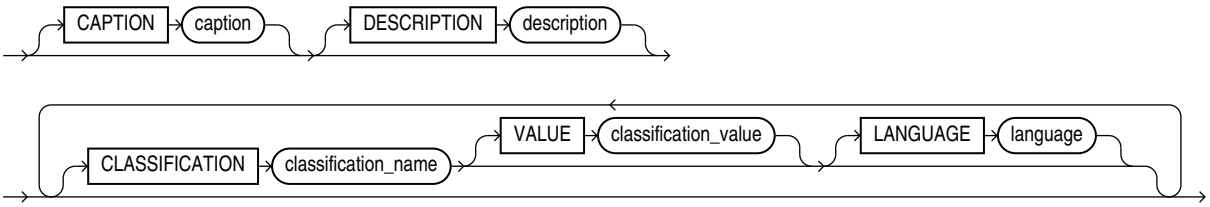
To create an analytic view in your own schema, you must have the `CREATE ANALYTIC VIEW` system privilege. To create an analytic view in another user's schema, you must have the `CREATE ANY ANALYTIC VIEW` system privilege.

Syntax

***create_analytic_view*::=**

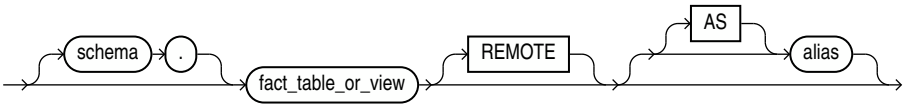


***classification_clause*::=**

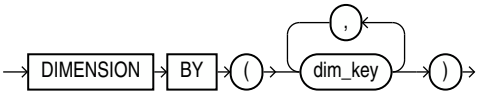


***using_clause*::=**

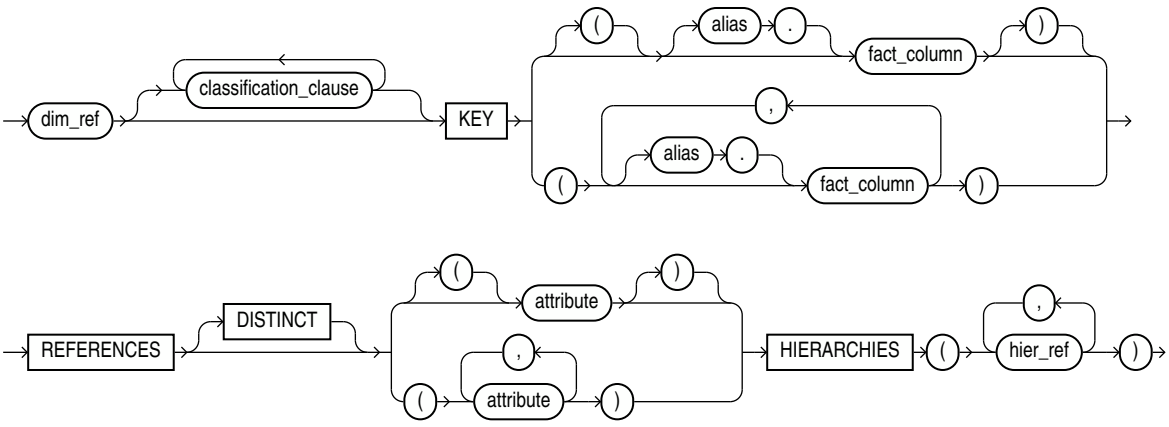
***source_clause*::=**



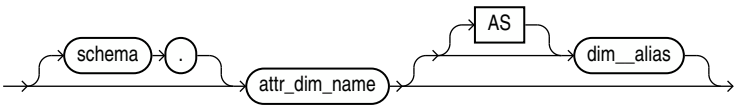
***dim_by_clause*::=**



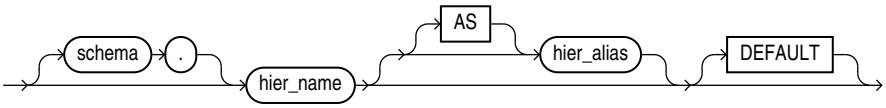
***dim_key*::=**



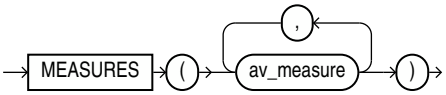
***dim_ref*::=**



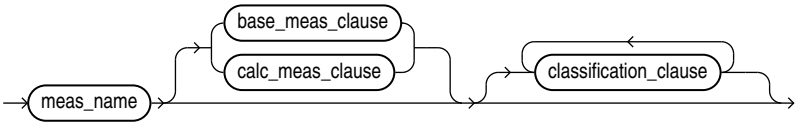
***hier_ref*::=**



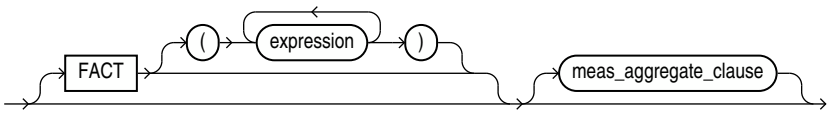
***measures_clause*::=**



***av_measure*::=**



***base_meas_clause*::=**



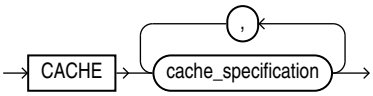
***calc_meas_clause*::=**

***meas_aggregate_clause*::=**

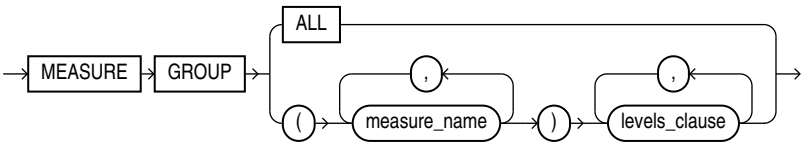
***default_measure_clause*::=**

***default_aggregate_clause*::=**

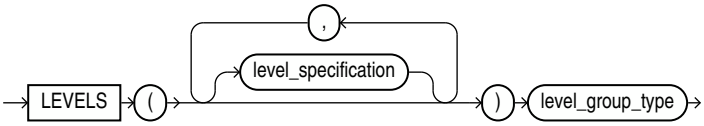
***cache_clause*::=**



***cache_specification*::=**

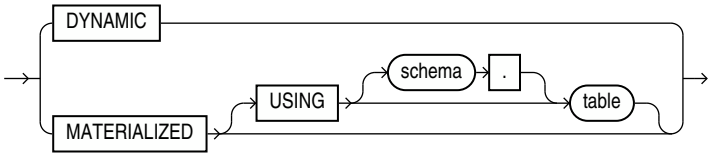


***levels_clause*::=**

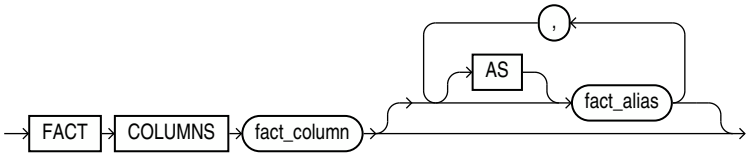


***level_specification*::=**

***level_group_type*::=**



***fact_columns_clause*::=**



***qry_transform_clause*::=**

Semantics

OR REPLACE

Specify `OR REPLACE` to replace an existing definition of an analytic view with a different definition.

FORCE and NOFORCE

Specify `FORCE` to force the creation of the analytic view even if it does not successfully compile. If you specify `NOFORCE`, then the analytic view must compile successfully, otherwise an error occurs. The default is `NOFORCE`.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the analytic view does not exist, a new analytic view is created at the end of the statement.
- If the analytic view exists, this is the analytic view you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

schema

Specify the schema in which to create the analytic view. If you do not specify a schema, then Oracle Database creates the analytic view in your own schema.

analytic_view_name

Specify a name for the analytic view.

SHARING

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- `METADATA` - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- `NONE` - The object is not shared and can only be accessed in the application root.

classification_clause

Use the classification clause to specify values for the `CAPTION` or `DESCRIPTION` classifications and to specify user-defined classifications. Classifications provide descriptive metadata that applications may use to provide information about analytic views and their components.

You may specify any number of classifications for the same object. A classification can have a maximum length of 4000 bytes.

For the `CAPTION` and `DESCRIPTION` classifications, you may use the DDL shortcuts `CAPTION '`*`caption`*`'` and `DESCRIPTION '`*`description`*`'` or the full classification syntax.

You may vary the classification values by language. To specify a language for the `CAPTION` or `DESCRIPTION` classification, you must use the full syntax. If you do not specify a language, then the language value for the classification is `NULL`. The language value must either be `NULL` or a valid `NLS_LANGUAGE` value.

using_clause

Use this clause to declare the sources that you want to use to build the analytic view.

source_clause

You can specify any of the following sources to build an analytic view:

- A fact table or a view.
- External tables and remote tables.
- A table or a view in another schema. You can specify an alias for the table or the view.

REMOTE

Specify `REMOTE` on a given source to indicate to the analytic view that the given source is backed by remote data and should be optimized as remote data.

dim_by_clause

Specify the attribute dimensions of the analytic view.

dim_key

Specify an attribute dimension, columns of the fact table, columns of the attribute dimension, and hierarchies that are related in the analytic view.

With the `KEY` keyword, specify one or more columns in the fact table.

With the `REFERENCES` keyword, specify attributes of the attribute dimensions that the analytic view is dimensioned by. Each attribute must be a level key. The `DISTINCT` keyword supports the use of denormalized fact tables, in which the attribute dimension and fact data are in the same table. Use `REFERENCES DISTINCT` when an attribute dimension is defined using the fact table.

With the `HIERARCHIES` keyword, specify the hierarchies in the analytic view that use the attribute dimension.

dim_ref

Specify an attribute dimension. You can specify an alias for an attribute dimension, which is required if you use the same dimension more than once or if you use multiple dimensions with the same name from different schemas.

hier_ref

Specify a hierarchy. You can specify an alias for a hierarchy. You can specify one of the hierarchies in the list as the default. If you do not specify a default, the first hierarchy in the list is the default.

measures_clause

Specify the measures for the analytic view.

av_measure

Define a measure using either a single fact column or an expression over measures in this analytic view. A measure can be either a base measure or a calculated measure.

base_measure_clause

Define a base measure by optionally specifying a fact column or a *`meas_aggregate_clause`*, or both. If you do not specify a fact column, then the analytic view uses the column of the fact table that has the same name as the measure. If a column by the same name does not exist, an error is raised.

calc_measure_clause

Define a calculated measure by specifying an analytic view expression. The expression may reference other measures in the analytic view, but may not reference fact columns. Calculated measures do not have an aggregate clause because they're computed over the aggregated base measures.

For the syntax and descriptions of analytic view expressions, see Analytic View Expressions.

default_measure_clause

Specify a measure to use as the default measure for the analytic view. If you do not specify a measure, the first measure defined is the default.

meas_aggregate_clausè

Specify a default aggregation function for a base measure. If you do not specify an aggregation function, then the function specified by the *`default_aggregate_clause`* is used.

aggr_function

The functions that you can aggregate by in the *meas_aggregate_clause* and *default_aggregate_clause* are the following: APPROX_COUNT_DISTINCT, APPROX_COUNT_DISTINCT_AGG, AVG, COUNT, MAX, MIN, STDDEV, STDDEV_POP, STDDEV_SAMP, SUM, VAR_POP, VAR_SAMP, and VARIANCE.

default_aggregate_clause

Specify a default aggregation function for all of the base measures in the analytic view. If you do not specify a default aggregation function, then the default value is SUM.

cache_clause

Specify a cache clause to improve query response time when an appropriate materialized view is available. You can specify one or more cache specifications.

cache_specification

Specify one or more measure groups for a cache clause. To include all measure groups, specify ALL. Each measure group can contain one or more measures and one or more level groupings. A level grouping can contain one or more level specifications.

level_specification

Specify one or more levels for a level grouping of a measure group for a cache specification. Specify only one level per hierarchy. A materialized view must exist that contains the aggregated values for the hierarchy level.

level_group_type

If you specify the USING clause, then the given table will be directly used at query time, if the analytic view determines that this is the best cache to use for the query. The typical shape of the cache is a column for each measure in the MEASURE GROUP plus a column per level key of each level in the cache. There is one row per member combination, across all given levels, that has at least one contributing row from the fact table. The column names of the given table must match a specific format so that the analytic view can identify which columns line up with which measures and level keys. The names of the columns can be retrieved from the DBMS_HIERARCHY package using the method GET_MV_SQL_FOR_AV_CACHE.

This method takes in the cache to generate SQL for and returns the SQL text for the cache. This SQL text can be used to create a materialized view for the cache. It can also be used to create an aggregate table using CREATE TABLE AS.

At compile time of the analytic view, the following checks will be made in regard to the materialized table:

- The table must exist and be accessible by the owner of the analytic view
- The columns of the table must include the expected cache columns

fact_columns_clause

Specify this clause to explictly state the fact columns that can be accessed by the dervided analytic view. You can aggregate any columns of the fact table that appear in *fact_columns_clause* at query time with the aggregation operator specified in the derived analytic view

If an alias is provided for the fact column, then the alias name must be used in the dervided analytic view. The alias defaults to the fact column name if not specified.

It is a semantic analysis error, if two or more fact columns are specified with the same name.

If you do not specify this clause, then no fact columns can be accessed for aggregation by the derived analytic view. This is the default.

qry_transform_clause

Specify this clause on an analytic view, if you want the view to participate in detecting queries that match its semantic model and transform it into an equivalent analytic view query if appropriate.

Restrictions

You cannot use *qry_transform_clause* on an analytic view in the following cases:

- When the analytic view contains an attribute dimension with more than one dimension table (either a snowflake or starflake schema)
- When a dimension table joins to the fact table at a level that is above the leaf level of the dimension (i.e. a `REFERENCES DISTINCT` join)
- When `NORELY` is specified and one or more base tables are remote tables

The new clause allows for an optional `RELY` or `NORELY` keyword. The default is `NORELY`.

The analytic view metadata can be viewed as a set of constraints on the underlying data. These constraints are not enforced by the database, but can be checked using the `DBMS_HIERARCHY.VALIDATE_ANALYTIC_VIEW` procedure.

The `RELY` keyword indicates that the constraints implied on the data by the analytic view metadata can be relied upon without validation when being considered for base table transform. If `NORELY` is specified, then the data must be in a valid state in relation to the metadata in order for the base table transform to take place.

Examples

The following is a description of the `SALES_FACT` table:

```
desc SALES_FACT
Name              Null? Type
----------------- ----- -------------
MONTH_ID                VARCHAR2(10)
CATEGORY_ID             NUMBER(6)
STATE_PROVINCE_ID       VARCHAR2(120)
UNITS                   NUMBER(6)
SALES                   NUMBER(12,2)
```

The following example creates the `SALES_AV` analytic view using the `SALES_FACT` table:

```
CREATE OR REPLACE ANALYTIC VIEW sales_av
USING sales_fact
DIMENSION BY
  (time_attr_dim                        -- An attribute dimension of time
data
    KEY month_id REFERENCES month_id
    HIERARCHIES (
```

```
      time_hier DEFAULT),
   product_attr_dim                       -- An attribute dimension of product
data
    KEY category_id REFERENCES category_id
    HIERARCHIES (
      product_hier DEFAULT),
   geography_attr_dim                     -- An attribute dimension of store
data
    KEY state_province_id
    REFERENCES state_province_id HIERARCHIES (
      geography_hier DEFAULT)
   )
MEASURES
 (sales FACT sales,                       -- A base measure
  units FACT units,                       -- A base measure
  sales_prior_period AS                   -- Calculated measures
    (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1)),
  sales_year_ago AS
    (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1
     ACROSS ANCESTOR AT LEVEL year)),
  chg_sales_year_ago AS
    (LAG_DIFF(sales) OVER (HIERARCHY time_hier OFFSET 1
     ACROSS ANCESTOR AT LEVEL year)),
  pct_chg_sales_year_ago AS
    (LAG_DIFF_PERCENT(sales) OVER (HIERARCHY time_hier OFFSET 1
     ACROSS ANCESTOR AT LEVEL year)),
  sales_qtr_ago AS
    (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1
     ACROSS ANCESTOR AT LEVEL quarter)),
  chg_sales_qtr_ago AS
    (LAG_DIFF(sales) OVER (HIERARCHY time_hier OFFSET 1
     ACROSS ANCESTOR AT LEVEL quarter)),
  pct_chg_sales_qtr_ago AS
    (LAG_DIFF_PERCENT(sales) OVER (HIERARCHY time_hier OFFSET 1
     ACROSS ANCESTOR AT LEVEL quarter))
  )
DEFAULT MEASURE SALES;
```

CREATE ATTRIBUTE DIMENSION

Purpose

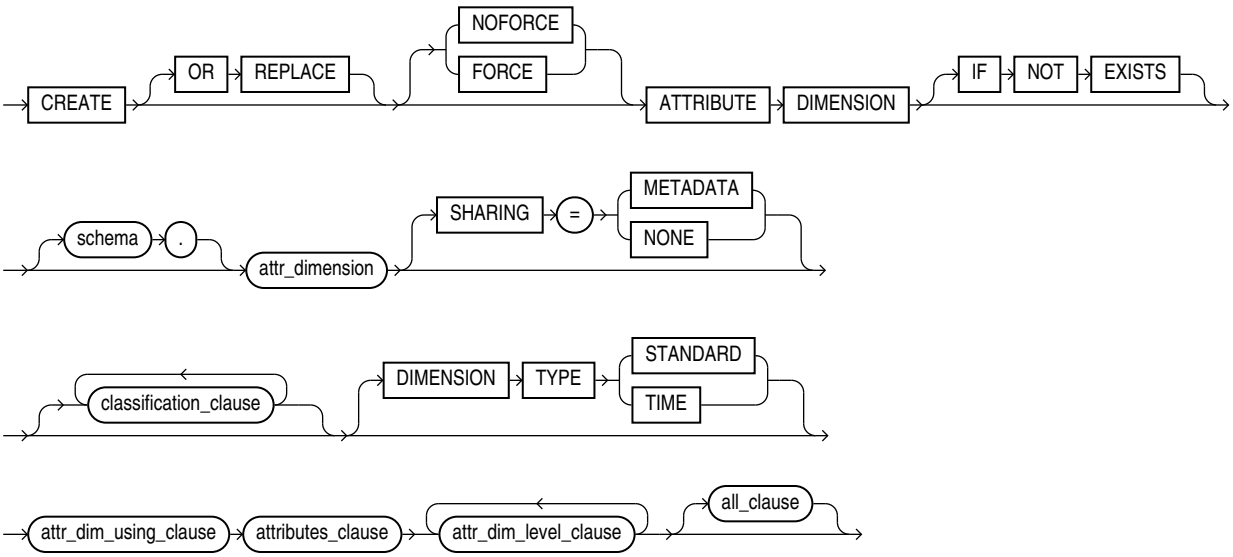
Use the `CREATE ATTRIBUTE DIMENSION` statement to create an attribute dimension. An attribute dimension specifies dimension members for one or more analytic view hierarchies. It specifies the data source it is using and the members it includes. It specifies levels for its members and determines attribute relationships between levels.

Prerequisites

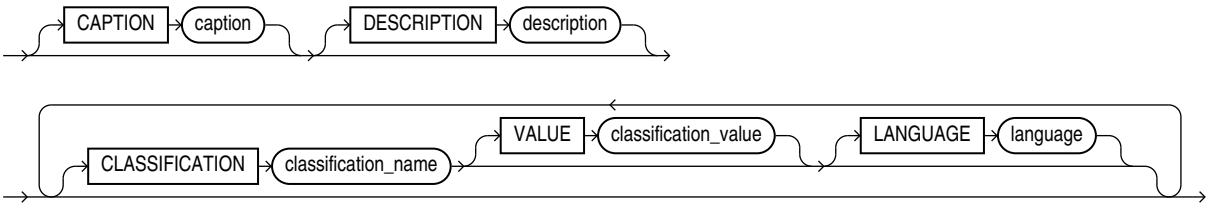
To create an attribute dimension in your own schema, you must have the `CREATE ATTRIBUTE DIMENSION` system privilege. To create an attribute dimension in another user's schema, you must have the `CREATE ANY ATTRIBUTE DIMENSION` system privilege.

Syntax

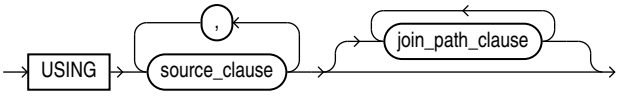
***create_attribute_dimension*::=**



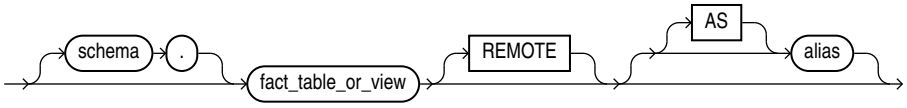
***classification_clause*::=**



***attr_dim_using_clause*::=**

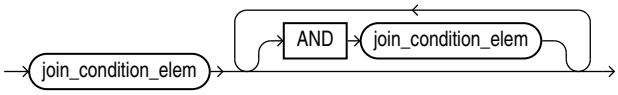


***source_clause*::=**

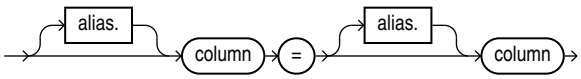


***join_path_clause*::=**

***join_condition*::=**

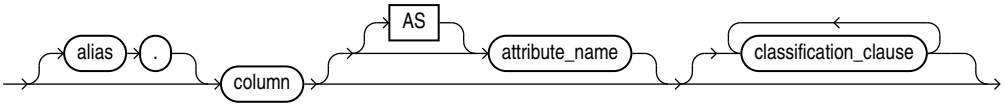


***join_condition_elem* ::=**

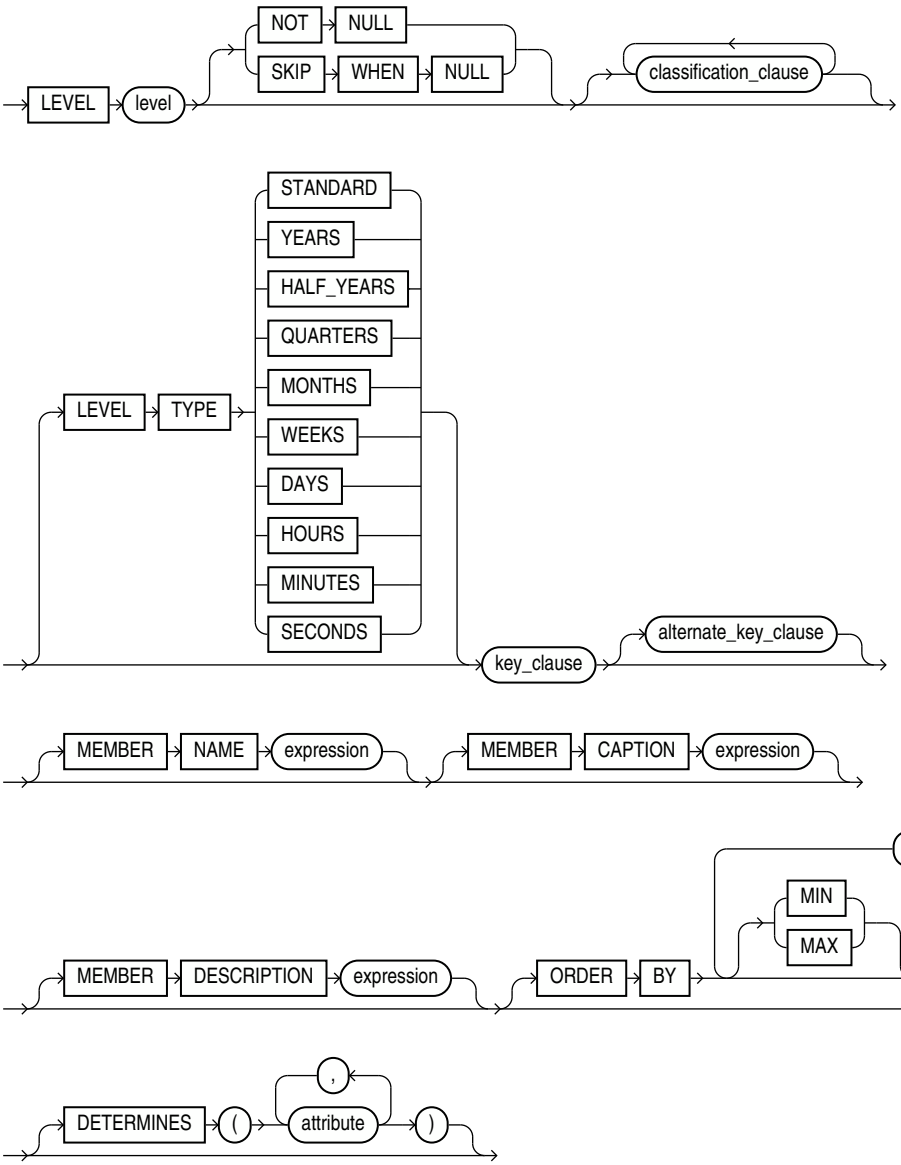


***attributes_clause*::=**

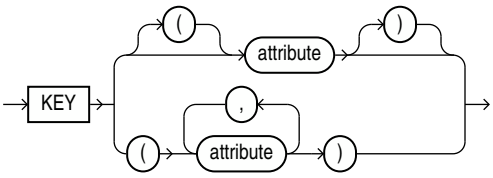
***attr_dim_attributes_clause*::=**



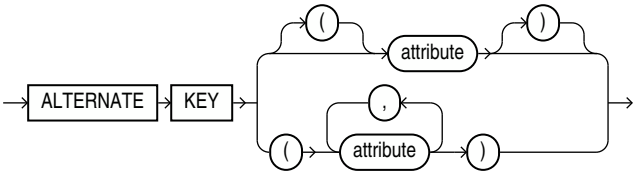
***attr_dim_level_clause*::=**



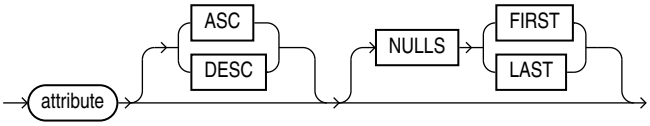
***key_clause*::=**



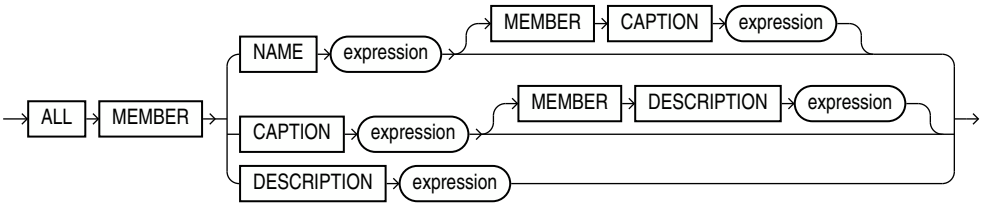
***alternate_key_clause*::=**



***dim_order_clause*::=**



***all_clause*::=**



Semantics

OR REPLACE

Specify `OR REPLACE` to replace an existing definition of an attribute dimension with a different definition.

FORCE and NOFORCE

Specify `FORCE` to force the creation of the attribute dimension even if it does not successfully compile. If you specify `NOFORCE`, then the attribute dimension must compile successfully, otherwise an error occurs. The default is `NOFORCE`.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the attribute dimension does not exist, a new attribute dimension is created at the end of the statement.
- If the attribute dimension exists, this is the attribute dimension you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement`.

schema

Specify the schema in which to create the attribute dimension. If you do not specify a schema, then Oracle Database creates the attribute dimension in your own schema.

attr_dimension

Specify a name for the attribute dimension.

SHARING

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- `METADATA` - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- `NONE` - The object is not shared and can only be accessed in the application root.

classification_clause

Use the classification clause to specify values for the `CAPTION` or `DESCRIPTION` classifications and to specify user-defined classifications. Classifications provide descriptive metadata that applications may use to provide information about analytic views and their components.

You may specify any number of classifications for the same object. A classification can have a maximum length of 4000 bytes.

For the `CAPTION` and `DESCRIPTION` classifications, you may use the DDL shortcuts `CAPTION 'caption'` and `DESCRIPTION 'description'` or the full classification syntax.

You may vary the classification values by language. To specify a language for the `CAPTION` or `DESCRIPTION` classification, you must use the full syntax. If you do not specify a language, then the language value for the classification is `NULL`. The language value must either be `NULL` or a valid `NLS_LANGUAGE` value.

DIMENSION TYPE

An attribute dimension may be either a `STANDARD` or a `TIME` type. A `STANDARD` type attribute dimension has `STANDARD` type levels. Each level of a `TIME` type attribute dimension is one of the time types. The default `DIMENSION TYPE` is `STANDARD`.

attr_dim_using_clause

Use this clause to declare the sources that you want to use to create the attribute dimension.

source_clause

You may specify the following sources:

- A table or a view.
- An alias for the table or the view by using the `AS` keyword.

- A join path. Use join paths to specify joins when the attribute dimension uses tables organized in a snowflake schema.

REMOTE

Specify `REMOTE` on a given source to indicate that the source is backed by remote data and should be optimized as remote data.

join_path_clause

The join path clause specifies a join condition between columns in different tables. The name for the join path specified by the *join_path_name* argument must be unique for each join path included in the `USING` clause.

join_condition

A join condition consists of one or more join condition elements; each additional join condition element is included by an `AND` operation.

join_condition_element

In a join condition element, the column references on the left-hand-side must come from a different table than the column references on the right-hand-side.

attributes_clause

Specify one or more *`attr_dim_attribute_clause`* clauses.

attr_dim_attribute_clause

Specify a column from the *`attr_dim_using_clause`* source. The attribute has the name of the column unless you specify an alias using the `AS` keyword. You may specify classifications for each attribute.

attr_dim_level_clause

Specify a level in the attribute dimension. A level specifies key and optional alternate key attributes that provide the members of the level.

If the key attribute has no `NULL` values, then you may specify `NOT NULL`, which is the default. If it does have one or more `NULL` values, then specify `SKIP WHEN NULL`.

LEVEL TYPE

A `STANDARD` type attribute dimension has `STANDARD` type levels. You do not need to specify a `LEVEL TYPE` for a `STANDARD` type attribute dimension.

In a `TIME` type attribute dimension, you must specify a level type. The type of the level may be one of the time types. You must specify a time type even if the values of the level members are not of that type. For example, you may have a SEASON level with values that are the names of seasons. In defining the level, you must specify any one of the time level types, such as `QUARTERS`. An application may use the level type designations for whatever purpose it chooses.

DETERMINES

With the `DETERMINES` keyword, you may specify other attributes of the attribute dimension that this level determines. If an attribute has only one value for each value of another attribute, then the value of the first attribute determines the value of the other attribute. For example, the QUARTER_ID attribute has only one value for each value of the MONTH_ID attribute, so you can include the the QUARTER_ID attribute in the `DETERMINES` phrase of the MONTHS level.

key_clause

Specify one or more attributes as the key for the level.

alternate_key_clause

Specify one or more attributes as the alternate key for the level.

dim_order_clause

Specify the ordering of the members of the level.

all_clause

Optionally specify `MEMBER NAME`, `MEMBER CAPTION`, and `MEMBER DESCRIPTION` values for the implicit ALL level. By default, the `MEMBER NAME` value is ALL.

Examples

The following example describes the TIME_DIM table:

```
desc TIME_DIM

Name               Null?   Type
------------------ -----   -------------
MONTH_ID                   VARCHAR2(10)
CATEGORY_ID                NUMBER(6)
STATE_PROVINCE_ID          VARCHAR2(120)
UNITS                      NUMBER(6)
SALES                      NUMBER(12,2)
YEAR_ID           NOT NULL VARCHAR2(30)
YEAR_NAME         NOT NULL VARCHAR2(40)
YEAR_END_DATE              DATE
QUARTER_ID        NOT NULL VARCHAR2(30)
QUARTER_NAME      NOT NULL VARCHAR2(40)
QUARTER_END_DATE           DATE
QUARTER_OF_YEAR            NUMBER
MONTH_ID          NOT NULL VARCHAR2(30)
MONTH_NAME        NOT NULL VARCHAR2(40)
MONTH_END_DATE             DATE
MONTH_OF_YEAR              NUMBER
MONTH_LONG_NAME            VARCHAR2(30)
SEASON                     VARCHAR2(10)
SEASON_ORDER               NUMBER(38)
MONTH_OF_QUARTER           NUMBER(38)
```

The following example creates a `TIME` type attribute dimension, using columns from the TIME_DIM table:

```
CREATE OR REPLACE ATTRIBUTE DIMENSION time_attr_dim
DIMENSION TYPE TIME
USING time_dim
ATTRIBUTES
 (year_id
   CLASSIFICATION caption VALUE 'YEAR_ID'
   CLASSIFICATION description VALUE 'YEAR ID',
```

```
  year_name
    CLASSIFICATION caption VALUE 'YEAR_NAME'
    CLASSIFICATION description VALUE 'Year',
  year_end_date
    CLASSIFICATION caption VALUE 'YEAR_END_DATE'
    CLASSIFICATION description VALUE 'Year End Date',
  quarter_id
    CLASSIFICATION caption VALUE 'QUARTER_ID'
    CLASSIFICATION description VALUE 'QUARTER ID',
  quarter_name
    CLASSIFICATION caption VALUE 'QUARTER_NAME'
    CLASSIFICATION description VALUE 'Quarter',
  quarter_end_date
    CLASSIFICATION caption VALUE 'QUARTER_END_DATE'
    CLASSIFICATION description VALUE 'Quarter End Date',
  quarter_of_year
    CLASSIFICATION caption VALUE 'QUARTER_OF_YEAR'
    CLASSIFICATION description VALUE 'Quarter of Year',
  month_id
    CLASSIFICATION caption VALUE 'MONTH_ID'
    CLASSIFICATION description VALUE 'MONTH ID',
  month_name
    CLASSIFICATION caption VALUE 'MONTH_NAME'
    CLASSIFICATION description VALUE 'Month',
  month_long_name
    CLASSIFICATION caption VALUE 'MONTH_LONG_NAME'
    CLASSIFICATION description VALUE 'Month Long Name',
  month_end_date
    CLASSIFICATION caption VALUE 'MONTH_END_DATE'
    CLASSIFICATION description VALUE 'Month End Date',
  month_of_quarter
    CLASSIFICATION caption VALUE 'MONTH_OF_QUARTER'
    CLASSIFICATION description VALUE 'Month of Quarter',
  month_of_year
    CLASSIFICATION caption VALUE 'MONTH_OF_YEAR'
    CLASSIFICATION description VALUE 'Month of Year',
  season
    CLASSIFICATION caption VALUE 'SEASON'
    CLASSIFICATION description VALUE 'Season',
  season_order
    CLASSIFICATION caption VALUE 'SEASON_ORDER'
    CLASSIFICATION description VALUE 'Season Order')
LEVEL month
  LEVEL TYPE MONTHS
  CLASSIFICATION caption VALUE 'MONTH'
  CLASSIFICATION description VALUE 'Month'
  KEY month_id
  MEMBER NAME month_name
  MEMBER CAPTION month_name
  MEMBER DESCRIPTION month_long_name
  ORDER BY month_end_date
  DETERMINES (month_end_date,
    quarter_id,
    season,
    season_order,
    month_of_year,
```

```
    month_of_quarter)
LEVEL quarter
  LEVEL TYPE QUARTERS
  CLASSIFICATION caption VALUE 'QUARTER'
  CLASSIFICATION description VALUE 'Quarter'
  KEY quarter_id
  MEMBER NAME quarter_name
  MEMBER CAPTION quarter_name
  MEMBER DESCRIPTION quarter_name
  ORDER BY quarter_end_date
  DETERMINES (quarter_end_date,
    quarter_of_year,
    year_id)
LEVEL year
  LEVEL TYPE YEARS
  CLASSIFICATION caption VALUE 'YEAR'
  CLASSIFICATION description VALUE 'Year'
  KEY year_id
  MEMBER NAME year_name
  MEMBER CAPTION year_name
  MEMBER DESCRIPTION year_name
  ORDER BY year_end_date
  DETERMINES (year_end_date)
LEVEL season
  LEVEL TYPE QUARTERS
  CLASSIFICATION caption VALUE 'SEASON'
  CLASSIFICATION description VALUE 'Season'
  KEY season
  MEMBER NAME season
  MEMBER CAPTION season
  MEMBER DESCRIPTION season
LEVEL month_of_quarter
  LEVEL TYPE MONTHS
  CLASSIFICATION caption VALUE 'MONTH_OF_QUARTER'
  CLASSIFICATION description VALUE 'Month of Quarter'
  KEY month_of_quarter;
```

The following example describes the PRODUCT_DIM table:

```
desc PRODUCT_DIM

Name            Null?    Type
--------------- -------- -------------
DEPARTMENT_ID   NOT NULL NUMBER
DEPARTMENT_NAME NOT NULL VARCHAR2(100)
CATEGORY_ID     NOT NULL NUMBER
CATEGORY_NAME   NOT NULL VARCHAR2(100)
```

The following example creates a `STANDARD` type attribute dimension, using columns from the PRODUCT_DIM table:

```
CREATE OR REPLACE ATTRIBUTE DIMENSION product_attr_dim
USING product_dim
ATTRIBUTES
 (department_id,
```

```
  department_name,
  category_id,
  category_name)
LEVEL DEPARTMENT
  KEY department_id
  ALTERNATE KEY department_name
  MEMBER NAME department_name
  MEMBER CAPTION department_name
  ORDER BY department_name
LEVEL CATEGORY
  KEY category_id
  ALTERNATE KEY category_name
  MEMBER NAME category_name
  MEMBER CAPTION category_name
  ORDER BY category_name
  DETERMINES(department_id)
ALL MEMBER NAME 'ALL PRODUCTS';
```

The following example describes the GEOGRAPHY_DIM table:

```
desc GEOGRAPHY_DIM

Name                Null?    Type
---------------     -------- -------------
DEPARTMENT_ID       NOT NULL NUMBER
DEPARTMENT_NAME     NOT NULL VARCHAR2(100)
CATEGORY_ID         NOT NULL NUMBER
CATEGORY_NAME       NOT NULL VARCHAR2(100)
REGION_ID           NOT NULL VARCHAR2(120)
REGION_NAME         NOT NULL VARCHAR2(100)
COUNTRY_ID          NOT NULL VARCHAR2(2)
COUNTRY_NAME        NOT NULL VARCHAR2(120)
STATE_PROVINCE_ID   NOT NULL VARCHAR2(120)
STATE_PROVINCE_NAME NOT NULL VARCHAR2(400)
```

The following example creates an `STANDARD` type attribute dimension, using columns from the GEOGRAPHY_DIM table:

```
CREATE OR REPLACE ATTRIBUTE DIMENSION geography_attr_dim
USING geography_dim
ATTRIBUTES
 (region_id,
  region_name,
  country_id,
  country_name,
  state_province_id,
  state_province_name)
LEVEL REGION
  KEY region_id
  ALTERNATE KEY region_name
  MEMBER NAME region_name
  MEMBER CAPTION region_name
  ORDER BY region_name
LEVEL COUNTRY
  KEY country_id
```

```
  ALTERNATE KEY country_name
  MEMBER NAME country_name
  MEMBER CAPTION country_name
  ORDER BY country_name
  DETERMINES(region_id)
LEVEL STATE_PROVINCE
  KEY state_province_id
  ALTERNATE KEY state_province_name
  MEMBER NAME state_province_name
  MEMBER CAPTION state_province_name
  ORDER BY state_province_name
  DETERMINES(country_id)
ALL MEMBER NAME 'ALL CUSTOMERS';
```

CREATE AUDIT POLICY (Unified Auditing)

This section describes the `CREATE AUDIT POLICY` statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12*c* and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

Purpose

Use the `CREATE AUDIT POLICY` statement to create a unified audit policy.

> **See Also:**
>
> - ALTER AUDIT POLICY (Unified Auditing)
> - DROP AUDIT POLICY (Unified Auditing)
> - AUDIT (Unified Auditing)
> - NOAUDIT (Unified Auditing)

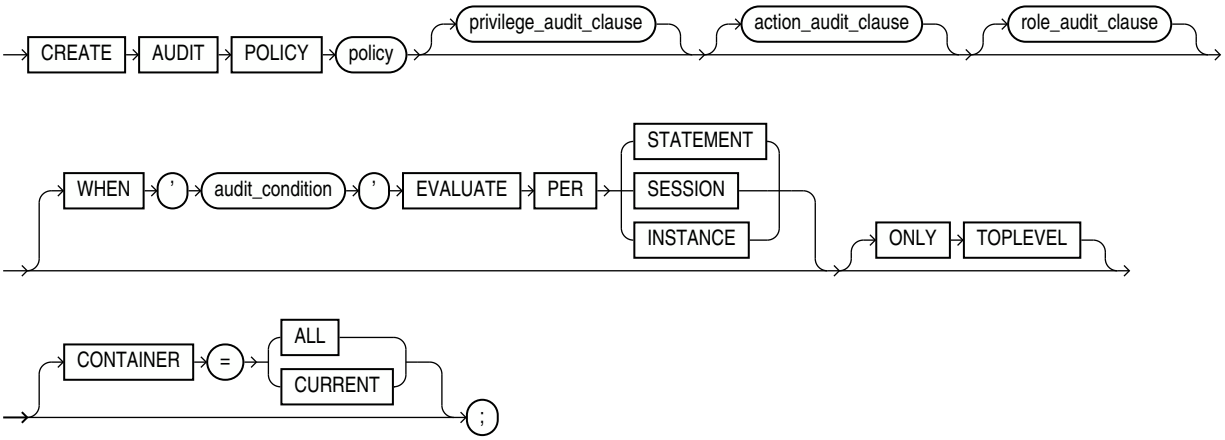
Prerequisites

You must have the `AUDIT SYSTEM` system privilege or the `AUDIT_ADMIN` role.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To create a common unified audit policy, you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role. To create a local unified audit policy, you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role, or you must have the locally granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` local role in the container to which you are connected.

Syntax

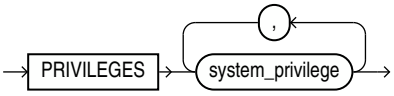
***create_audit_policy*::=**



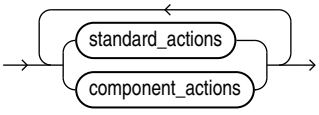
> **Note:**
>
> You must specify at least one of the clauses *privilege_audit_clause*, *action_audit_clause*, or *role_audit_clause*.

(*privilege_audit_clause*::=, *action_audit_clause*::=, *role_audit_clause*::=)

***privilege_audit_clause*::=**

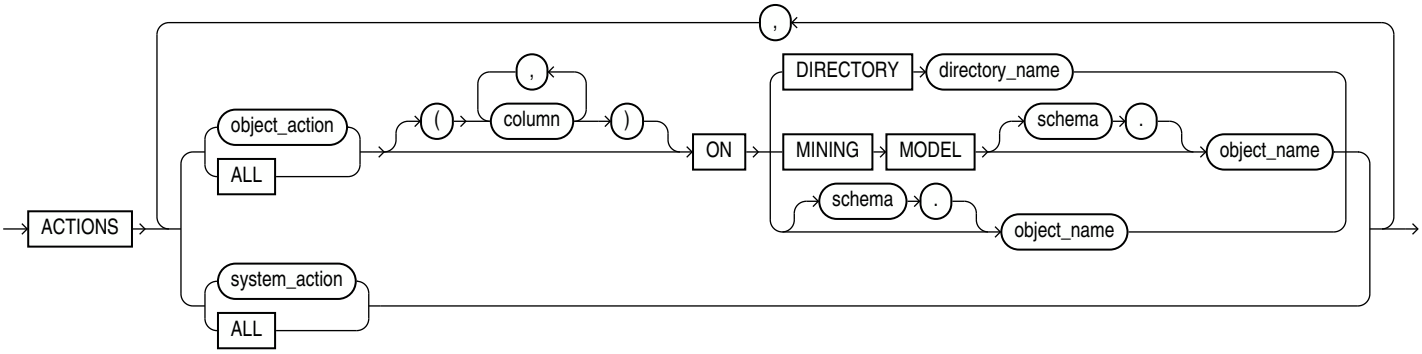


***action_audit_clause*::=**

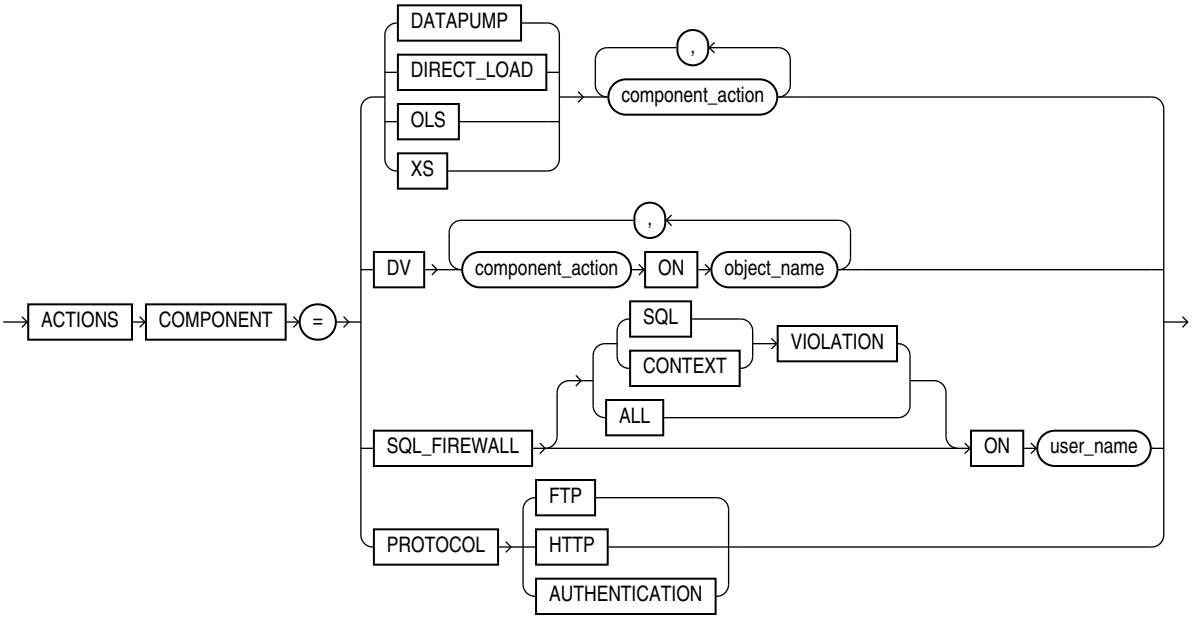


> **Note:**
>
> You can specify only the *standard_actions* clause, only the *component_actions* clause, or both clauses in either order, but you can specify each clause at most once.

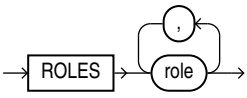
***standard_actions*::=**



***component_actions*::=**



***role_audit_clause*::=**



Semantics

policy

Specify the name of the unified audit policy to be created. The name of the policy must begin with the value of the `COMMON_USER_PREFIX` initialization parameter. The default value of the `COMMON_USER_PREFIX` parameter is `c##`.

The length of the audit policy name cannot exceed 128 bytes and must contain ASCII characters only.

These rules apply for application common audit policies as well. In this case, the value of the `COMMON_USER_PREFIX` is fetched from the application root. The default value in application root is an empty string.

The name must also satisfy the requirements listed in "Database Object Naming Rules ".

You can find the names of all unified audit policies by querying the `AUDIT_UNIFIED_POLICIES` view.

> **See Also:**
>
> *Oracle Database Reference* for more information on the `AUDIT_UNIFIED_POLICIES` view

privilege_audit_clause

Use this clause to audit one or more system privileges. For *`system_privilege`*, specify a valid system privilege. To view all valid system privileges, query the `NAME` column of the `SYSTEM_PRIVILEGE_MAP` view.

Only those SQL statements are audited, that successfully use system privileges. If a statement does not make use of a system privilege, it does not get audited with the *`privilege_audit_clause`*.

Restriction on Auditing System Privileges

You cannot audit the following system privileges: `INHERIT ANY PRIVILEGES`, `SYSASM`, `SYSBACKUP`, `SYSDBA`, `SYSDG`, `SYSKM`, `SYSRAC`, and `SYSOPER`.

action_audit_clause

Use this clause to specify one or more actions to be audited. Use the *`standard_actions`* clause to audit actions on standard RDBMS objects and to audit standard RDBMS system actions for the database. Use the *`component_actions`* clause to audit actions for components.

standard_actions

Use this clause to audit actions on standard RDBMS objects and to audit standard RDBMS system actions for the database.

You can also create unified audit policies to audit individual columns in tables and views. For examples on auditing columns see Examples

Note that column level audit policies generate audit records whenever the column is accessed.

***object_action* ON**

Use this clause to audit an action on the specified object. For *`object_action`*, specify the action to be audited. Table 13-1 lists the actions that can be audited on each type of object.

ALL ON

Use this clause to audit all actions on the specified object. All of the actions listed in Table 13-1 for the type of object that you specify in the `ON` clause will be audited.

ON Clause

Use the ON clause to specify the object to be audited. Directories and data mining models are identified separately because they reside in separate namespaces. To audit actions on a directory, specify ON DIRECTORY *directory_name*. To audit actions on a data mining model, specify ON MINING MODEL *object_name*. To audit actions on the other types of objects listed in Table 13-1, specify ON *object_name*. If you do not qualify *object_name* with *schema*, then the database assumes the object is in your own schema.

Table 13-1 Unified Auditing Objects and Actions

Type of Object	Actions
Directory	AUDIT, GRANT, READ
Function	AUDIT, EXECUTE (Notes 1 and 2), GRANT
Java Schema Objects (Source, Class, Resource)	AUDIT, EXECUTE, GRANT
Library	EXECUTE, GRANT
Materialized Views	ALTER, AUDIT, COMMENT, DELETE, INDEX, INSERT, LOCK, SELECT, UPDATE
Mining Model	AUDIT, COMMENT, GRANT, RENAME, SELECT
Object Type	ALTER, AUDIT, GRANT
Package	AUDIT, EXECUTE, GRANT
Procedure	AUDIT, EXECUTE (Notes 1 and 2), GRANT
Sequence	ALTER, AUDIT, GRANT, SELECT
Table	ALTER, AUDIT, COMMENT, DELETE, FLASHBACK, GRANT, INDEX, INSERT, LOCK, RENAME, SELECT, UPDATE, TRUNCATE
View	AUDIT, DELETE, FLASHBACK, GRANT, INSERT, LOCK, RENAME, SELECT, UPDATE

Note 1: When you audit the EXECUTE operation on a PL/SQL stored procedure or stored function, the database considers only its ability to find the procedure or function and authorize its execution when determining the success or failure of the operation for the purposes of auditing. Therefore, if you specify the WHENEVER NOT SUCCESSFUL clause, then only invalid object errors, non-existent object errors, and authorization failures are audited; errors encountered during the execution of the procedure or function are not audited. If you specify the WHENEVER SUCCESSFUL clause, then all executions that are not blocked by invalid object errors, non-existent object errors, or authorization failures are audited, regardless of whether errors are encountered during execution.

Note 2: To audit the failure of a recursive SQL operation inside a PL/SQL stored procedure or stored function, configure auditing for the SQL operation.

Note 3: The auditing of EXECUTE on a PL/SQL stored procedure, function, or package in the database happens during the instantiation phase of the procedure, function, or package.

Note 3: The auditing of the GRANT object audit option also audits the REVOKE audit option.

system_action

Use this clause to audit a system action for the database. To view the valid values for *system_action*, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is 'Standard'.

Example: Audit CHANGE PASSWORD in Unified Auditing

You can audit `CHANGE PASSWORD` system actions by configuring an audit policy to audit password changes. After you configure the audit policy, you must enable the audit policy.

Example: Create Audit Policy to Audit System Action Change Password

The following example creates an audit policy `mypolicy` to audit the action `CHANGE PASSWORD`:

```
CREATE AUDIT POLICY mypolicy ACTIONS CHANGE PASSWORD;
----------------------
Audit policy created.
```

Example: Enable Audit Policy Configured to Audit Password Changes

The following statement enables the audit policy `mypolicy`:

```
AUDIT POLICY mypolicy;
```

The audit policy `mypolicy` will now audit `CHANGE PASSWORD` actions for both successful and unsuccessful changes of password.

Example: Change Password

A user `hr_usr` with password `hr_pwd` can connect to PDB `hr_pdb` and change the password as follows:

```
CONNECT hr_usr/hr_pwd@hr_pdb;
PASSWORD
Changing password for hr_usr
Old password:
New password:
Retype new password:
Password changed.
```

In the SQL*Plus example above, the command `PASSWORD` run by user `hr_usr` initiates a `CHANGE PASSWORD` action that generates an audit record.

Example: Check Audit Trail for Password Changes

You can view the record by by querying the `UNIFIED_AUDIT_TRAIL` as follows:

```
SELECT ACTION_NAME, UNIFIED_AUDIT_POLICIES, OBJECT_NAME FROM UNIFIED_AUDIT_TRAIL;

ACTION_NAME
--------------------------------------------------------------------
UNIFIED_AUDIT_POLICIES
--------------------------------------------------------------------
OBJECT_NAME
--------------------------------------------------------------------
CHANGE PASSWORD
MYPOLICY
HR_USR
```

Note that the audit policy `mypolicy` will not capture password changes via the `ALTER USER` statement.

ALL

Use this clause to audit all system actions for the database.

component_actions

Use this clause to audit actions for the following components: Oracle Data Pump, Oracle SQL*Loader Direct Path Load, Oracle Label Security, Oracle Database Real Application Security, Oracle Database Vault, and the transmission protocol.

DATAPUMP

Use this clause to audit actions for Oracle Data Pump. For *component_action*, specify the action to be audited. To view the valid actions for Oracle Data Pump, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is Datapump. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'Datapump';
```

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Data Pump.

DIRECT_LOAD

Use this clause to audit actions for Oracle SQL*Loader Direct Path Load. For *component_action*, specify the action to be audited. To view the valid actions for Oracle SQL*Loader Direct Path Load, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is Direct path API. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'Direct path API';
```

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle SQL*Loader Direct Path Load.

OLS

Use this clause to audit actions for Oracle Label Security. For *component_action*, specify the action to be audited. To view the valid actions for Oracle Label Security, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is Label Security. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'Label Security';
```

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Label Security.

XS

Use this clause to audit actions for Oracle Database Real Application Security. For *component_action*, specify the action to be audited. To view the valid actions for Oracle Database Real Application Security, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is XS. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'XS';
```

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Database Real Application Security.

DV

Use this clause to audit actions for Oracle Database Vault. For *component_action*, specify the action to be audited. To view the valid actions for Oracle Database Vault, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is Database Vault. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'Database Vault';
```

For *object_name*, specify the name of the Database Vault object to be audited.

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Database Vault.

SQL_FIREWALL

Use this clause to set the unified audit policy to track SQL firewall violations.

PROTOCOL

Use the `PROTOCOL` component to audit FTP and HTTP messages.

Example 1: Audit all HTTP Messages

```
CREATE AUDIT POLICY mypolicy ACTIONS COMPONENT = PROTOCOL HTTP;
    AUDIT POLICY mypolicy;
```

Example 2: Audit Failed FTP Messages

```
CREATE AUDIT POLICY mypolicy ACTIONS COMPONENT = PROTOCOL FTP;
    AUDIT POLICY mypolicy WHENEVER NOT SUCCESSFUL;
```

Example 3: Audit HTTP Messages that had 401 AUTH Replies

```
CREATE AUDIT POLICY mypolicy ACTIONS COMPONENT = PROTOCOL AUTHENTICATION;
    AUDIT POLICY mypolicy;
```

role_audit_clause

Use this clause to specify one or more roles to be audited. When you audit a role, Oracle Database audits all system privileges that are granted directly to the role. SQL statements that require the system privileges in order to succeed are audited. For *role*, specify either a user-defined (local or external) or predefined role. For a list of predefined roles, refer to *Oracle Database Security Guide*.

WHEN Clause

Use this clause to control when the unified audit policy is enforced.

audit_condition

Specify a condition that determines if the unified audit policy is enforced. If *audit_condition* evaluates to `TRUE`, then the policy is enforced. If `FALSE`, then the policy is not enforced.

The *audit_condition* can have a maximum length of 4000 characters. It can contain expressions, as well as the following functions and conditions:

- Numeric functions: `BITAND`, `CEIL`, `FLOOR`, `POWER`
- Character functions returning character values: `CONCAT`, `LOWER`, `UPPER`
- Character functions returning number values: `INSTR`, `LENGTH`
- Environment and identifier functions: `SYS_CONTEXT`, `UID`
- Comparison conditions: `=`, `!=`, `<>`, `<`, `>`, `<=`, `>=`
- Logical conditions: `AND`, `OR`
- Null conditions: `IS [NOT] NULL`
- `[NOT] BETWEEN` condition
- `[NOT] IN` condition

The *audit_condition* must be enclosed in single quotation marks. If the *audit_condition* contains a single quotation mark, then specify two single quotation marks instead. For example, to specify the following condition:

```
SYS_CONTEXT('USERENV', 'CLIENT_IDENTIFIER') = 'myclient'
```

Specify the following for '*audit_condition*':

```
'SYS_CONTEXT(''USERENV'', ''CLIENT_IDENTIFIER'') = ''myclient'''
```

The EVALUATE PER clauses evaluate the audit condition per instance per container. For example, if a condition is evaluated in one container, it will be evaluated again in any other container even if the instance is same.

EVALUATE PER STATEMENT

Specify this clause to evaluate the *audit_condition* for each auditable statement for each instance in the container. If the *audit_condition* evaluates to TRUE, then the unified audit policy is enforced for the statement. If FALSE, then the unified audit policy is not enforced for the statement.

EVALUATE PER SESSION

Specify this clause to evaluate the *audit_condition* once during the session. The *audit_condition* is evaluated for the first auditable statement that is executed during the session. If the *audit_condition* evaluates to TRUE, then the unified audit policy is enforced for all applicable statements for the rest of the session. If FALSE, then the unified audit policy is not enforced for all applicable statements for the rest of the session.

EVALUATE PER INSTANCE

Specify this clause to evaluate the *audit_condition* once during the lifetime of the instance. The *audit_condition* is evaluated for the first auditable statement that is executed during the instance lifetime. If the *audit_condition* evaluates to TRUE, then the unified audit policy is enforced for all applicable statements for the rest of the lifetime of the instance. If FALSE, then the unified audit policy is not enforced for all applicable statements for the rest of the lifetime of the instance.

ONLY TOPLEVEL

Specify the ONLY TOPLEVEL clause when you want to audit the SQL statements issued directly by a user.

SQL statements that are run from within a PL/SQL procedure are not considered top-level statements. You can audit top-level statements from all users, including user SYS.

For more see *Database Security Guide*.

CONTAINER Clause

Use the CONTAINER clause to specify the scope of the unified audit policy.

- Specify CONTAINER = ALL to create a **common unified audit policy**. This type of policy is available to all pluggable databases (PDBs) in the CDB. The current container must be the root. If you specify the ACTIONS *object_action* ON or ACTIONS ALL ON clause, then you must specify a common object or an application common object.
- Specify CONTAINER = CURRENT to create a **local unified audit policy** in the current container. The current container can be the root or a PDB.

If you omit this clause, then CONTAINER = CURRENT is the default.

> **Note:**
>
> You cannot alter the scope of a unified audit policy after it has been created.

Examples

Auditing System Privileges: Example

The following statement creates unified audit policy `table_pol`, which audits the system privileges `CREATE ANY TABLE` and `DROP ANY TABLE`:

```
CREATE AUDIT POLICY table_pol
  PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE;
```

The following statement verifies that `table_pol` now appears in the `AUDIT_UNIFIED_POLICIES` view:

```
SELECT *
  FROM audit_unified_policies
  WHERE policy_name = 'TABLE_POL';
```

Auditing Actions on Objects: Examples

The following statement creates unified audit policy `dml_pol`, which audits `DELETE`, `INSERT`, and `UPDATE` actions on table `hr.employees`, and all auditable actions on table `hr.departments`:

```
CREATE AUDIT POLICY dml_pol
  ACTIONS DELETE on hr.employees,
          INSERT on hr.employees,
          UPDATE on hr.employees,
          ALL on hr.departments;
```

The following statement creates unified audit policy `read_dir_pol`, which audits `READ` actions on directory `bfile_dir` (created in "Creating a Directory: Examples"):

```
CREATE AUDIT POLICY read_dir_pol
  ACTIONS READ ON DIRECTORY bfile_dir;
```

Auditing System Actions: Examples

The following query displays the standard RDBMS system actions that can be audited for the database:

```
SELECT name FROM auditable_system_actions
  WHERE component = 'Standard'
  ORDER BY name;

NAME
----
ADMINISTER KEY MANAGEMENT
ALL
ALTER ASSEMBLY
ALTER AUDIT POLICY
ALTER CLUSTER
...
```

The following statement creates unified audit policy `security_pol`, which audits the system action `ADMINISTER KEY MANAGEMENT`:

```
CREATE AUDIT POLICY security_pol
  ACTIONS ADMINISTER KEY MANAGEMENT;
```

The following statement creates unified audit policy `dir_pol`, which audits all read, write, and execute operations on any directory:

```
CREATE AUDIT POLICY dir_pol
  ACTIONS READ DIRECTORY, WRITE DIRECTORY, EXECUTE DIRECTORY;
```

See *31.4.4.11 Example: Auditing All Actions in the Database* of the *Database Security Guide* for guidelines to audit database actions without generating a large volume of audit records.

Auditing Component Actions: Example

The following query displays the actions that can be audited for Oracle Data Pump:

```
SELECT name FROM auditable_system_actions
  WHERE component = 'Datapump';

NAME
----
EXPORT
IMPORT
ALL
```

The following statement creates unified audit policy `dp_actions_pol`, which audits `IMPORT` actions for Oracle Data Pump:

```
CREATE AUDIT POLICY dp_actions_pol
  ACTIONS COMPONENT = datapump IMPORT;
```

Auditing Roles: Example

The following statement creates unified audit policy `java_pol`, which audits the predefined roles `java_admin` and `java_deploy`:

```
CREATE AUDIT POLICY java_pol
  ROLES java_admin, java_deploy;
```

Auditing System Privileges, Actions, and Roles: Example

The following statement creates unified audit policy `hr_admin_pol`, which audits multiple system privileges, actions, and roles:

```
CREATE AUDIT POLICY hr_admin_pol
  PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
  ACTIONS DELETE on hr.employees,
          INSERT on hr.employees,
          UPDATE on hr.employees,
          ALL on hr.departments,
          LOCK TABLE
  ROLES audit_admin, audit_viewer;
```

Controlling When a Unified Audit Policy is Enforced: Examples

The following statement creates unified audit policy `order_updates_pol`, which audits `UPDATE` actions on table `oe.orders`. This policy is enforced only when the auditable statement is issued by an external user. The audit condition is checked once per session.

```
CREATE AUDIT POLICY order_updates_pol
  ACTIONS UPDATE ON oe.orders
  WHEN 'SYS_CONTEXT(''USERENV'', ''IDENTIFICATION_TYPE'') = ''EXTERNAL'''
  EVALUATE PER SESSION;
```

The following statement creates unified audit policy `emp_updates_pol`, which audits `DELETE`, `INSERT`, and `UPDATE` actions on table `hr.employees`. This policy is enforced only when the auditable statement is issued by a user who does not have a UID of 100, 105, or 107. The audit condition is checked for each auditable statement.

```
CREATE AUDIT POLICY emp_updates_pol
        ACTIONS DELETE on hr.employees,
          INSERT on hr.employees,
          UPDATE on hr.employees
        WHEN 'UID NOT IN (100, 105, 107)'
        EVALUATE PER STATEMENT;
```

Creating a Local Unified Audit Policy: Example

The following statement creates local unified audit policy `local_table_pol`, which audits the system privileges `CREATE ANY TABLE` and `DROP ANY TABLE` in the current container:

```
CREATE AUDIT POLICY local_table_pol
       PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
       CONTAINER = CURRENT;
```

Creating a Common Unified Audit Policy: Example

The following statement creates common unified audit policy `common_role1_pol`, which audits the common role `c##role1` (created in `CREATE ROLE` "Examples") across the entire CDB:

```
CREATE AUDIT POLICY c##common_role1_pol
      ROLES c##role1
      CONTAINER = ALL;
```

Creating an Audit Policy on Columns: Example

The audit policy `pol` generates an audit record when granting privileges on the column `job` in the `emp` table.

```
CREATE AUDIT POLICY pol ACTIONS GRANT(job) on scott.emp;
```

The audit policy `pol` generates an audit record when a new department number is inserted into the `dept` table.

```
CREATE AUDIT POLICY pol ACTIONS INSERT(deptno) on scott.dept;
```

CREATE CLUSTER

Purpose

Use the `CREATE CLUSTER` statement to create a cluster. A **cluster** is a schema object that contains data from one or more tables.

- An **indexed cluster** must contain more than one table, and all of the tables in the cluster have one or more columns in common. Oracle Database stores together all the rows from all the tables that share the same cluster key.
- In a **hash cluster**, which can contain one or more tables, Oracle Database stores together rows that have the same hash key value.

For information on existing clusters, query the `USER_CLUSTERS`, `ALL_CLUSTERS`, and `DBA_CLUSTERS` data dictionary views.

> **See Also:**
>
> - *Oracle Database Concepts* for general information on clusters
> - *Oracle Database SQL Tuning Guide* for suggestions on when to use clusters
> - *Oracle Database Reference* for information on the data dictionary views

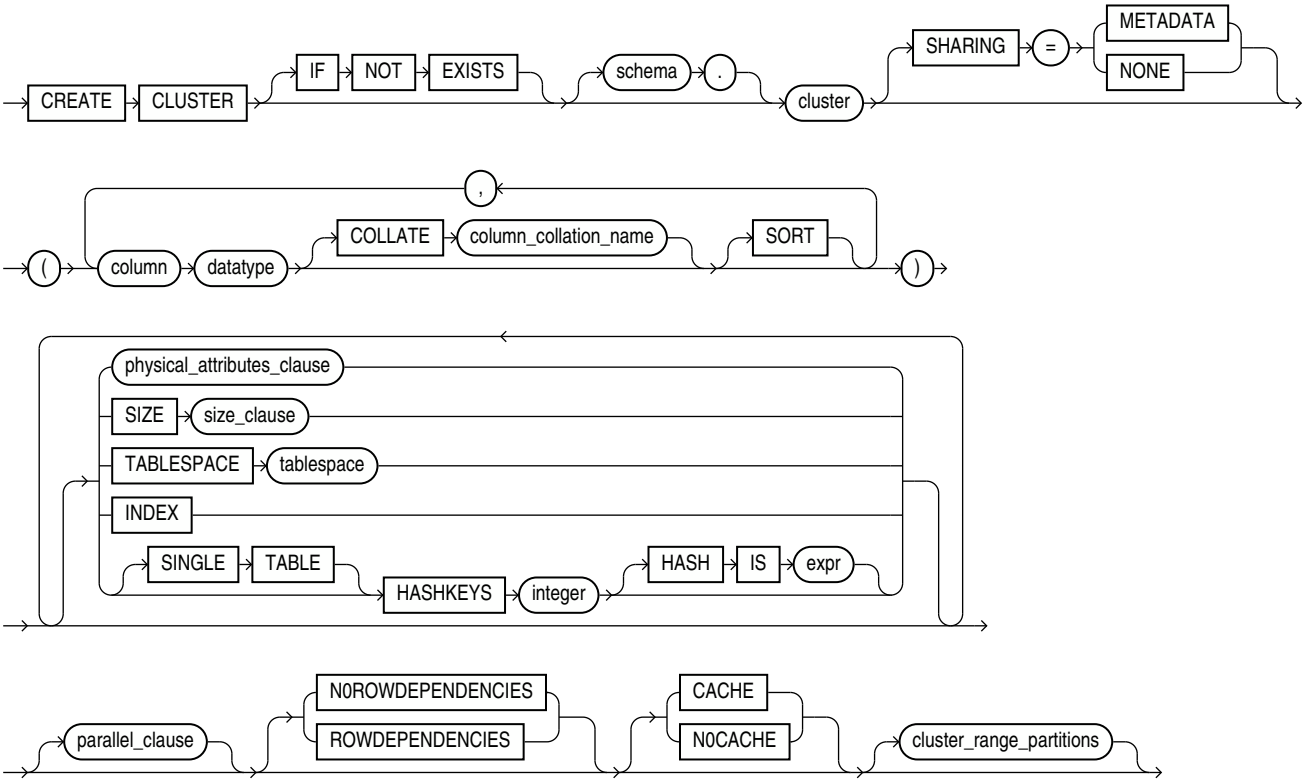
Prerequisites

To create a cluster in your own schema, you must have `CREATE CLUSTER` system privilege. To create a cluster in another user's schema, you must have `CREATE ANY CLUSTER` system privilege. Also, the owner of the schema to contain the cluster must have either space quota on the tablespace containing the cluster or the `UNLIMITED TABLESPACE` system privilege.

Oracle Database does not automatically create an index for a cluster when the cluster is initially created. Data manipulation language (DML) statements cannot be issued against cluster tables in an indexed cluster until you create a cluster index with a `CREATE INDEX` statement.

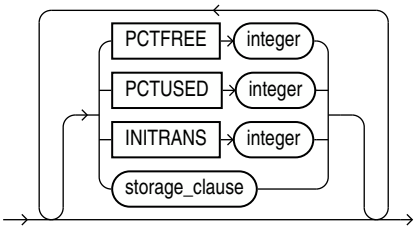
Syntax

***create_cluster*::=**



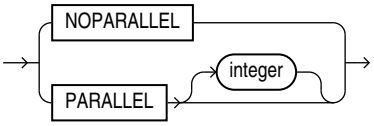
(*datatype*::=,*physical_attributes_clause*::=, *size_clause*::=, *cluster_range_partitions*::=)

***physical_attributes_clause*::=**

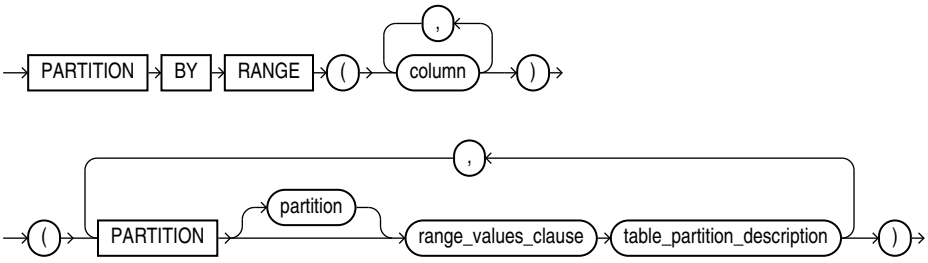


(*storage_clause*::=)

***parallel_clause*::=**



***cluster_range_partitions*::=**



(*range_values_clause*::=, *table_partition_description*::=)

Semantics

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the cluster does not exist, a new cluster is created at the end of the statement.
- If the cluster exists, this is the cluster you have at the end of the statement. A new one is not created because the older cluster is detected.

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

schema

Specify the schema to contain the cluster. If you omit *schema*, then Oracle Database creates the cluster in your current schema.

cluster

Specify is the name of the cluster to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

After you create a cluster, you add tables to it. A cluster can contain a maximum of 32 tables. Object tables and tables containing LOB columns or columns of the `Any*` Oracle-supplied types cannot be part of a cluster. After you create a cluster and add tables to it, the cluster is transparent. You can access clustered tables with SQL statements just as you can access nonclustered tables.

> **See Also:**
>
> CREATE TABLE for information on adding tables to a cluster, "Creating a Cluster: Example", and "Adding Tables to a Cluster: Example"

SHARING

Use the sharing clause if you want to create the cluster in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- `METADATA` - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- `NONE` - The object is not shared and can only be accessed in the application root.

column

Specify one or more names of columns in the cluster key. You can specify up to 16 cluster key columns. These columns must correspond in both data type and size to columns in each of the clustered tables, although they need not correspond in name.

You cannot specify integrity constraints as part of the definition of a cluster key column. Instead, you can associate integrity constraints with the tables that belong to the cluster.

> **See Also:**
>
> "Cluster Keys: Example"

datatype

Specify the data type of each cluster key column.

Restrictions on Cluster Data Types

Cluster data types are subject to the following restrictions:

- You cannot specify a cluster key column of data type `LONG`, `LONG RAW`, `REF`, nested table, varray, `BLOB`, `CLOB`, `BFILE`, the `Any*` Oracle-supplied types, or user-defined object type.
- You can specify a column of type `ROWID`, but Oracle Database does not guarantee that the values in such columns are valid rowids.

> **See Also:**
>
> "Data Types " for information on data types

COLLATE

Use this clause to specify the data-bound collation for character data type columns in the cluster key.

For *column_collation_name*, specify the collation as follows:

- When creating an indexed cluster or a sorted hash cluster, you can specify one of the following collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.
- When creating a hash cluster that is not sorted, you can specify any valid named collation or pseudo-collation.

If you omit this clause, then columns in the cluster key inherit the effective schema default collation of the schema containing the cluster. Refer to the DEFAULT_COLLATION clause of `ALTER SESSION` for more information on the effective schema default collation.

The collations of cluster key columns must match the collations of the corresponding columns in the tables created in the cluster.

You can specify the `COLLATE` clause only if the `COMPATIBLE` initialization parameter is set to `12.2` or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

To change the collation of a cluster key column, you must recreate the cluster.

SORT

The `SORT` keyword is valid only if you are creating a hash cluster. Table rows are hashed into buckets on cluster key columns without `SORT`, and then sorted in each bucket on the columns with this clause. This may improve response time during subsequent queries on the clustered data.

All columns without the `SORT` clause must come before all columns with the `SORT` clause in the `CREATE CLUSTER` statement.

Restriction on Sorted Hash Clusters

Row dependency is not supported for sorted hash clusters.

> **See Also:**
>
> - See "HASHKEYS Clause" for information on creating a hash cluster.
> - *Managing Hash Clusters* for more information.

physical_attributes_clause

The *physical_attributes_clause* lets you specify the storage characteristics of the cluster. Each table in the cluster uses these storage characteristics as well. If you do not specify values for these parameters, then Oracle Database uses the following defaults:

- PCTFREE: 10
- PCTUSED: 40
- INITRANS: 2 or the default value of the tablespace to contain the cluster, whichever is greater

> **See Also:**
>
> *physical_attributes_clause* and storage_clause for a complete description of these clauses

SIZE

Specify the amount of space in bytes reserved to store all rows with the same cluster key value or the same hash value. This space determines the maximum number of cluster or hash values stored in a data block. If SIZE is not a divisor of the data block size, then Oracle Database uses the next largest divisor. If SIZE is larger than the data block size, then the database uses the operating system block size, reserving at least one data block for each cluster or hash value.

The database also considers the length of the cluster key when determining how much space to reserve for the rows having a cluster key value. Larger cluster keys require larger sizes. To see the actual size, query the KEY_SIZE column of the USER_CLUSTERS data dictionary view. (This value does not apply to hash clusters, because hash values are not actually stored in the cluster.)

If you omit this parameter, then the database reserves one data block for each cluster key value or hash value.

TABLESPACE

Specify the tablespace in which the cluster is to be created.

INDEX Clause

Specify INDEX to create an **indexed cluster**. In an indexed cluster, Oracle Database stores together rows having the same cluster key value. Each distinct cluster key value is stored only once in each data block, regardless of the number of tables and rows in which it occurs. If you specify neither INDEX nor HASHKEYS, then Oracle Database creates an indexed cluster by default.

After you create an indexed cluster, you must create an index on the cluster key before you can issue any data manipulation language (DML) statements against a table in the cluster. This index is called the **cluster index**.

You cannot create a cluster index for a hash cluster, and you need not create an index on a hash cluster key.

> **See Also:**
>
> CREATE INDEX for information on creating a cluster index and *Oracle Database Concepts* for general information in indexed clusters

HASHKEYS Clause

Specify the `HASHKEYS` clause to create a **hash cluster** and specify the number of hash values for the hash cluster. In a hash cluster, Oracle Database stores together rows that have the same hash key value. The hash value for a row is the value returned by the hash function of the cluster.

Oracle Database rounds up the `HASHKEYS` value to the nearest prime number to obtain the actual number of hash values. The minimum value for this parameter is 2. If you omit both the `INDEX` clause and the `HASHKEYS` parameter, then the database creates an indexed cluster by default.

When you create a hash cluster, the database immediately allocates space for the cluster based on the values of the `SIZE` and `HASHKEYS` parameters.

> **See Also:**
>
> *Oracle Database Concepts* for more information on how Oracle Database allocates space for clusters and "Hash Clusters: Examples"

SINGLE TABLE

`SINGLE TABLE` indicates that the cluster is a type of hash cluster containing only one table. This clause can provide faster access to rows in the table.

Restriction on Single-table Clusters

Only one table can be present in the cluster at a time. However, you can drop the table and create a different table in the same cluster.

> **See Also:**
>
> "Single-Table Hash Clusters: Example"

HASH IS *expr*

Specify an expression to be used as the hash function for the hash cluster. The expression:

- Must evaluate to a positive value
- Must contain at least one column, with referenced columns of any data type as long as the entire expression evaluates to a number of scale 0. For example: *`number_column`* * `LENGTH`(*`varchar2_column`*)
- Cannot reference user-defined PL/SQL functions
- Cannot reference the pseudocolumns `LEVEL` or `ROWNUM`

- Cannot reference the user-related functions `USERENV`, `UID`, or `USER` or the datetime functions `CURRENT_DATE`, `CURRENT_TIMESTAMP`, `DBTIMEZONE`, `EXTRACT` (datetime), `FROM_TZ`, `LOCALTIMESTAMP`, `NUMTODSINTERVAL`, `NUMTOYMINTERVAL`, `SESSIONTIMEZONE`, `SYSDATE`, `SYSTIMESTAMP`, `TO_DSINTERVAL`, `TO_TIMESTAMP`, `TO_DATE`, `TO_TIMESTAMP_TZ`, `TO_YMINTERVAL`, and `TZ_OFFSET`.
- Cannot evaluate to a constant
- Cannot be a scalar subquery expression
- Cannot contain columns qualified with a schema or object name (other than the cluster name)

If you omit the `HASH IS` clause, then Oracle Database uses an internal hash function for the hash cluster.

For information on existing hash functions, query the `USER_`, `ALL_`, and `DBA_CLUSTER_HASH_EXPRESSIONS` data dictionary tables.

The cluster key of a hash column can have one or more columns of any data type. Hash clusters with composite cluster keys or cluster keys made up of noninteger columns must use the internal hash function.

> **See Also:**
>
> *Oracle Database Reference* for information on the data dictionary views

parallel_clause

The *parallel_clause* lets you parallelize the creation of the cluster.

For complete information on this clause, refer to *parallel_clause* in the documentation on `CREATE TABLE`.

NOROWDEPENDENCIES | ROWDEPENDENCIES

This clause has the same behavior for a cluster that it has for a table. Refer to "NOROWDEPENDENCIES | ROWDEPENDENCIES" in `CREATE TABLE` for information.

CACHE | NOCACHE

CACHE

Specify `CACHE` if you want the blocks retrieved for this cluster to be placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This clause is useful for small lookup tables.

NOCACHE

Specify `NOCACHE` if you want the blocks retrieved for this cluster to be placed at the least recently used end of the LRU list in the buffer cache when a full table scan is performed. This is the default behavior.

`NOCACHE` has no effect on clusters for which you specify `KEEP` in the *storage_clause*.

cluster_range_partitions

Specify the *cluster_range_partitions* clause to create a range-partitioned hash cluster. If you specify this clause, then you must also specify the HASHKEYS clause.

Use the *cluster_range_partitions* clause to partition the cluster on ranges of values from the column list. When you add a table to a range-partitioned hash cluster, it is automatically partitioned on the same columns, with the same number of partitions, and on the same partition bounds as the cluster. Oracle Database assigns system-generated names to the table partitions.

Each partitioning key column with a character data type must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

The *cluster_range_partitions* clause has the same semantics as the *range_partitions* clause of CREATE TABLE, except that here you cannot specify the INTERVAL clause. For complete information, refer to *range_partitions* in the documentation on CREATE TABLE.

> **See Also:**
>
> "Range-Partitioned Hash Clusters: Example"

Examples

Creating a Cluster: Example

The following statement creates a cluster named personnel with the cluster key column department, a cluster size of 512 bytes, and storage parameter values:

```
CREATE CLUSTER personnel
   (department NUMBER(4))
SIZE 512
STORAGE (initial 100K next 50K);
```

Cluster Keys: Example

The following statement creates the cluster index on the cluster key of personnel:

```
CREATE INDEX idx_personnel ON CLUSTER personnel;
```

After creating the cluster index, you can add tables to the index and perform DML operations on those tables.

Adding Tables to a Cluster: Example

The following statements create some departmental tables from the sample hr.employees table and add them to the personnel cluster created in the earlier example:

```
CREATE TABLE dept_10
   CLUSTER personnel (department_id)
   AS SELECT * FROM employees WHERE department_id = 10;

CREATE TABLE dept_20
   CLUSTER personnel (department_id)
   AS SELECT * FROM employees WHERE department_id = 20;
```

Hash Clusters: Examples

The following statement creates a hash cluster named `language` with the cluster key column `cust_language`, a maximum of 10 hash key values, each of which is allocated 512 bytes, and storage parameter values:

```
CREATE CLUSTER language (cust_language VARCHAR2(3))
   SIZE 512 HASHKEYS 10
   STORAGE (INITIAL 100k next 50k);
```

Because the preceding statement omits the `HASH IS` clause, Oracle Database uses the internal hash function for the cluster.

The following statement creates a hash cluster named `address` with the cluster key made up of the columns `postal_code` and `country_id`, and uses a SQL expression containing these columns for the hash function:

```
CREATE CLUSTER address
   (postal_code NUMBER, country_id CHAR(2))
   HASHKEYS 20
   HASH IS MOD(postal_code + country_id, 101);
```

Single-Table Hash Clusters: Example

The following statement creates a single-table hash cluster named `cust_orders` with the cluster key `customer_id` and a maximum of 100 hash key values, each of which is allocated 512 bytes:

```
CREATE CLUSTER cust_orders (customer_id NUMBER(6))
   SIZE 512 SINGLE TABLE HASHKEYS 100;
```

Range-Partitioned Hash Clusters: Example

The following statement creates a range-partitioned hash cluster named `sales` with five range partitions based on the amount sold. The cluster key is made up of the columns `amount_sold` and `prod_id`. The cluster uses the hash function `(amount_sold * 10 + prod_id)` and has a maximum of 100000 hash key values, each of which is allocated 300 bytes.

```
CREATE CLUSTER sales (amount_sold NUMBER, prod_id NUMBER)
  HASHKEYS 100000
  HASH IS (amount_sold * 10 + prod_id)
  SIZE 300
  TABLESPACE example
  PARTITION BY RANGE (amount_sold)
    (PARTITION p1 VALUES LESS THAN (2001),
     PARTITION p2 VALUES LESS THAN (4001),
     PARTITION p3 VALUES LESS THAN (6001),
     PARTITION p4 VALUES LESS THAN (8001),
     PARTITION p5 VALUES LESS THAN (MAXVALUE));
```

Create Cluster Tables: Example

The following statement creates a cluster named `emp_dept` with the default key size (600):

```
CREATE CLUSTER emp_dept (deptno NUMBER(3))
   SIZE 600
   TABLESPACE USERS
   STORAGE (INITIAL 200K
      NEXT 300K
      MINEXTENTS 2
      PCTINCREASE 33);
```

The following statement creates a cluster table named `dept` under `emp_dept` cluster:

```
CREATE TABLE dept (
   deptno NUMBER(3) PRIMARY KEY)
   CLUSTER emp_dept (deptno);
```

The following statement creates another cluster table named `empl` under `emp_dept` cluster:

```
CREATE TABLE empl (
   emplno NUMBER(5) PRIMARY KEY,
   emplname VARCHAR2(15) NOT NULL,
   deptno NUMBER(3) REFERENCES dept)
   CLUSTER emp_dept (deptno);
```

The following statement creates an index for the `emp_dept` cluster:

```
CREATE INDEX emp_dept_index
   ON CLUSTER emp_dept
   TABLESPACE USERS
   STORAGE (INITIAL 50K
      NEXT 50K
      MINEXTENTS 2
      MAXEXTENTS 10
      PCTINCREASE 33);
```

The following statement queries `USER_CLUSTERS` to display the cluster metadata:

```
SELECT CLUSTER_NAME, TABLESPACE_NAME, CLUSTER_TYPE, PCT_INCREASE,
MIN_EXTENTS, MAX_EXTENTS FROM USER_CLUSTERS;

CLUSTER_NAME    TABLESPACE CLUST PCT_INCREASE MIN_EXTENTS MAX_EXTENTS
--------------- ---------- ----- ------------ ----------- -----------
EMP_DEPT    USERS       INDEX            1  2147483645
```

The following statement queries `USER_CLU_COLUMNS` to display the cluster metadata:

```
SELECT * FROM USER_CLU_COLUMNS;

CLUSTER_NAME    CLU_COLUMN_NAME      TABLE_NAME TAB_COLUMN_NAME
--------------- -------------------- ---------- --------------------
EMP_DEPT    DEPTNO             DEPT    DEPTNO
EMP_DEPT    DEPTNO             EMPL    DEPTNO
```

The following statement queries `USER_INDEXES` to display the index attributes of the `emp_dept` cluster:

```
SELECT INDEX_NAME, INDEX_TYPE, PCT_INCREASE, MIN_EXTENTS, MAX_EXTENTS FROM
USER_INDEXES WHERE TABLE_NAME='EMP_DEPT';

INDEX_NAME    INDEX_TYPE    PCT_INCREASE MIN_EXTENTS MAX_EXTENTS
--------------- --------------- ------------ ----------- -----------
EMP_DEPT_INDEX    CLUSTER                   1  2147483645
```

CREATE CONTEXT

Purpose

Use the `CREATE CONTEXT` statement to:

- Create a namespace for a **context** (a set of application-defined attributes that validates and secures an application)
- Associate the namespace with the externally created package that sets the context

You can use the `DBMS_SESSION.SET_CONTEXT` procedure in your designated package to set or reset the attributes of the context.

> **See Also:**
>
> - *Oracle Database Security Guide* for a discussion of contexts
> - *Oracle Database PL/SQL Packages and Types Reference* for information on the `DBMS_SESSION.SET_CONTEXT` procedure

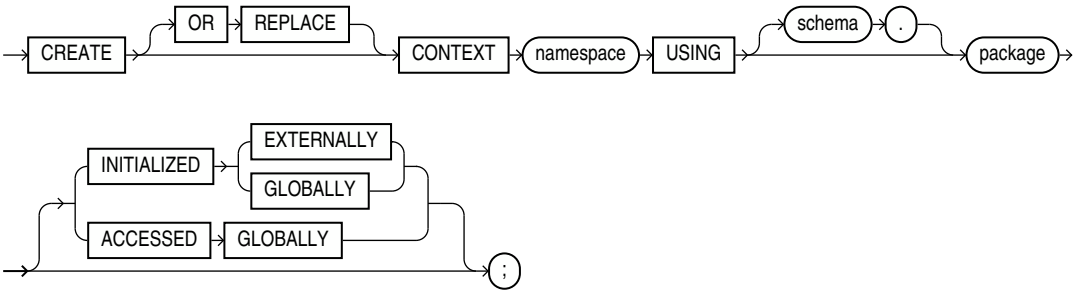
Prerequisites

To create a context namespace, you must have `CREATE ANY CONTEXT` system privilege.

Note that you cannot use a synonym for a package name in the `CREATE CONTEXT` command.

Syntax

***create_context*::=**



Semantics

OR REPLACE

Specify `OR REPLACE` to redefine an existing context namespace using a different package.

namespace

Specify the name of the context namespace to create or modify. The name must satisfy the requirements listed in "Database Object Naming Rules ". Context namespaces are always stored in the schema `SYS`.

> **See Also:**
>
> "Database Object Naming Rules " for guidelines on naming a context namespace

schema

Specify the schema owning *package*. If you omit *schema*, then Oracle Database uses the current schema.

package

Specify the PL/SQL package that sets or resets the context attributes under the namespace for a user session.

To provide some design flexibility, Oracle Database does not verify the existence of the schema or the validity of the package at the time you create the context.

SHARING

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- `METADATA` - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- `NONE` - The object is not shared and can only be accessed in the application root.

INITIALIZED Clause

The `INITIALIZED` clause lets you specify an entity other than Oracle Database that can initialize the context namespace.

EXTERNALLY

`EXTERNALLY` indicates that the namespace can be initialized using an OCI interface when establishing a session.

> **See Also:**
>
> *Oracle Call Interface Programmer's Guide* for information on using OCI to establish a session

GLOBALLY

`GLOBALLY` indicates that the namespace can be initialized by the LDAP directory when a global user connects to the database.

After the session is established, only the designated PL/SQL package can issue commands to write to any attributes inside the namespace.

> **See Also:**
>
> *Oracle Database Security Guide* for information on establishing globally initialized contexts

ACCESSED GLOBALLY

This clause indicates that any application context set in *namespace* is accessible throughout the entire instance. This setting lets multiple sessions share application attributes.

Examples

Creating an Application Context: Example

This example uses a PL/SQL package `emp_mgmt`, which validates and secures a human resources application. See *Oracle Database PL/SQL Language Reference* for the example that creates that package. The following statement creates the context namespace `hr_context` and associates it with the package `emp_mgmt`:

```
CREATE CONTEXT hr_context USING emp_mgmt;
```

You can control data access based on this context using the `SYS_CONTEXT` function. For example, the `emp_mgmt` package has defined an attribute `department_id` as a particular department identifier. You can secure the base table `employees` by creating a view that restricts access based on the value of `department_id`, as follows:

```
CREATE VIEW hr_org_secure_view AS
   SELECT * FROM employees
   WHERE department_id = SYS_CONTEXT('hr_context', 'department_id');
```

> **See Also:**
>
> SYS_CONTEXT and *Oracle Database Security Guide* for more information on using application contexts to retrieve user information

CREATE CONTROLFILE

> **Note:**
>
> Oracle recommends that you perform a full backup of all files in the database before using this statement. For more information, see *Oracle Database Backup and Recovery User's Guide*.

Purpose

The `CREATE CONTROLFILE` statement should be used in only a few cases. Use this statement to re-create a control file if all control files being used by the database are lost **and** no backup control file exists. You can also use this statement to change the maximum number of redo log

file groups, redo log file members, archived redo log files, data files, or instances that can concurrently have the database mounted and open.

To change the name of the database, Oracle recommends that you use the `DBNEWID` utility rather than the `CREATE CONTROLFILE` statement. `DBNEWID` is preferable because no `OPEN RESETLOGS` operation is required after changing the database name.

> **See Also:**
>
> - *Oracle Database Utilities* for more information about the `DBNEWID` utility
> - `ALTER DATABASE` "BACKUP CONTROLFILE Clause" for information creating a script based on an existing database control file

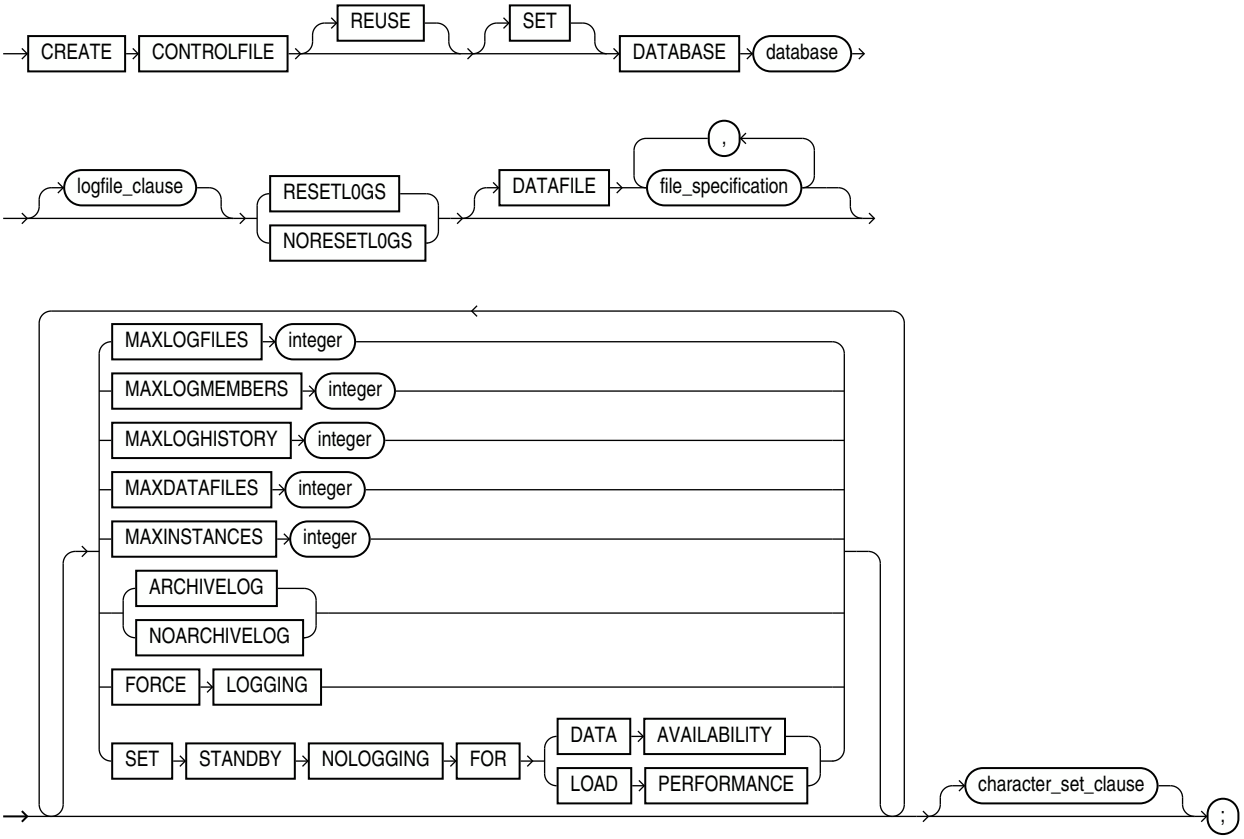
Prerequisites

To create a control file, you must have the `SYSDBA` or `SYSBACKUP` system privilege.

The database must not be mounted by any instance. After successfully creating the control file, Oracle mounts the database in the mode specified by the `CLUSTER_DATABASE` parameter. The DBA must then perform media recovery before opening the database. If you are using the database with Oracle Real Application Clusters (Oracle RAC), then you must then shut down and remount the database in `SHARED` mode (by setting the value of the `CLUSTER_DATABASE` initialization parameter to `TRUE`) before other instances can start up.

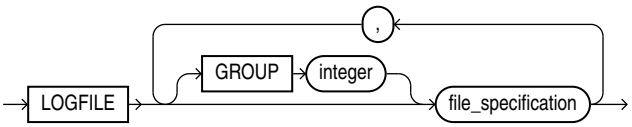
Syntax

***create_controlfile*::=**



(*storage_clause*::=)

***logfile_clause*::=**



(*file_specification*::=)

***character_set_clause*::=**

Semantics

When you issue a `CREATE CONTROLFILE` statement, Oracle Database creates a new control file based on the information you specify in the statement. The control file resides in the location

specified in the CONTROL_FILES initialization parameter. If that parameter does not have a value, then the database creates an Oracle-managed control file in the default control file destination, which is one of the following (in order of precedence):

1. One or more control files as specified in the DB_CREATE_ONLINE_LOG_DEST_*n* initialization parameter. The file in the first directory is the primary control file. When DB_CREATE_ONLINE_LOG_DEST_*n* is specified, the database does not create a control file in DB_CREATE_FILE_DEST or in DB_RECOVERY_FILE_DEST (the fast recovery area).
2. If no value is specified for DB_CREATE_ONLINE_LOG_DEST_*n*, but values are set for both the DB_CREATE_FILE_DEST and DB_RECOVERY_FILE_DEST, then the database creates one control file in each location. The location specified in DB_CREATE_FILE_DEST is the primary control file.
3. If a value is specified only for DB_CREATE_FILE_DEST, then the database creates one control file in that location.
4. If a value is specified only for DB_RECOVERY_FILE_DEST, then the database creates one control file in that location.

If no values are set for any of these parameters, then the database creates a control file in the default location for the operating system on which the database is running. This control file is not an Oracle Managed File.

If you omit any clauses, then Oracle Database uses the default values rather than the values for the previous control file. After successfully creating the control file, Oracle Database mounts the database in the mode specified by the initialization parameter CLUSTER_DATABASE. If that parameter is not set, then the default value is FALSE, and the database is mounted in EXCLUSIVE mode. Oracle recommends that you then shut down the instance and take a full backup of all files in the database.

> **See Also:**
>
> *Oracle Database Backup and Recovery User's Guide*

REUSE

Specify REUSE to indicate that existing control files identified by the initialization parameter CONTROL_FILES can be reused, overwriting any information they may currently contain. If you omit this clause and any of these control files already exists, then Oracle Database returns an error.

DATABASE Clause

Specify the name of the database. The value of this parameter must be the existing database name established by the previous CREATE DATABASE statement or CREATE CONTROLFILE statement.

SET DATABASE Clause

Use SET DATABASE to change the name of the database. The name of a database can be as long as eight bytes.

When you specify this clause, you must also specify RESETLOGS. If you want to rename the database and retain your existing log files, then after issuing this CREATE CONTROLFILE

statement you must complete a full database recovery using an `ALTER DATABASE RECOVER USING BACKUP CONTROLFILE` statement.

logfile_clause

Use the *logfile_clause* to specify the redo log files for your database. You must list all members of all redo log file groups.

Use the *redo_log_file_spec* form of *file_specification* (see *file_specification*) to list regular redo log files in an operating system file system or to list Oracle ASM disk group redo log files. When using a form of *ASM_filename*, you cannot specify the *autoextend_clause* of the *redo_log_file_spec*.

If you specify `RESETLOGS` in this clause, then you must use one of the file creation forms of *ASM_filename*. If you specify `NORESETLOGS`, then you must specify one of the reference forms of *ASM_filename*.

> **See Also:**
>
> *ASM_filename* for information on the different forms of syntax and *Oracle Automatic Storage Management Administrator's Guide* for general information about using Oracle ASM

GROUP *integer*

Specify the logfile group number. If you specify `GROUP` values, then Oracle Database verifies these values with the `GROUP` values when the database was last open.

If you omit this clause, then the database creates logfiles using system default values. In addition, if either the `DB_CREATE_ONLINE_LOG_DEST_n` or `DB_CREATE_FILE_DEST` initialization parameter has been set, and if you have specified `RESETLOGS`, then the database creates two logs in the default logfile destination specified in the `DB_CREATE_ONLINE_LOG_DEST_n` parameter, and if it is not set, then in the `DB_CREATE_FILE_DEST` parameter.

> **See Also:**
>
> *file_specification* for a full description of this clause

RESETLOGS

Specify `RESETLOGS` if you want Oracle Database to ignore the contents of the files listed in the `LOGFILE` clause. These files do not have to exist. You must specify this clause if you have specified the `SET DATABASE` clause.

Each *redo_log_file_spec* in the `LOGFILE` clause must specify the `SIZE` parameter. The database assigns all online redo log file groups to thread 1 and enables this thread for public use by any instance. After using this clause, you must open the database using the `RESETLOGS` clause of the `ALTER DATABASE` statement.

NORESETLOGS

Specify `NORESETLOGS` if you want Oracle Database to use all files in the `LOGFILE` clause as they were when the database was last open. These files must exist and must be the current online redo log files rather than restored backups. The database reassigns the redo log file groups to the threads to which they were previously assigned and reenables the threads as they were previously enabled.

You cannot specify `NORESETLOGS` if you have specified the `SET DATABASE` clause to change the name of the database. Refer to "SET DATABASE Clause" for more information.

DATAFILE Clause

Specify the data files of the database. You must list all data files. These files must all exist, although they may be restored backups that require media recovery.

Do not include in the `DATAFILE` clause any data files in read-only tablespaces. You can add these types of files to the database later. Also, do not include in this clause any temporary data files (temp files).

Use the *`datafile_tempfile_spec`* form of *`file_specification`* (see *file_specification*) to list regular data files and temp files in an operating system file system or to list Oracle ASM disk group files. When using a form of *`ASM_filename`*, you must use one of the reference forms of *`ASM_filename`*. Refer to *ASM_filename* for information on the different forms of syntax.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for general information about using Oracle ASM

Restriction on DATAFILE

You cannot specify the *`autoextend_clause`* of *`file_specification`* in this `DATAFILE` clause.

MAXLOGFILES Clause

Specify the maximum number of online redo log file groups that can ever be created for the database. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The default and maximum values depend on your operating system. The value that you specify should not be less than the greatest `GROUP` value for any redo log file group.

MAXLOGMEMBERS Clause

Specify the maximum number of members, or identical copies, for a redo log file group. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The minimum value is 1. The maximum and default values depend on your operating system.

MAXLOGHISTORY Clause

This parameter is useful only if you are using Oracle Database in `ARCHIVELOG` mode. Specify your current estimate of the maximum number of archived redo log file groups needed for automatic media recovery of the database. The database uses this value to determine how much space to allocate in the control file for the names of archived redo log files.

The minimum value is 0. The default value is a multiple of the MAXINSTANCES value and depends on your operating system. The maximum value is limited only by the maximum size of the control file. The database will continue to add additional space to the appropriate section of the control file as needed, so that you do not need to re-create the control file if your your original configuration is no longer adequate. As a result, the actual value of this parameter can eventually exceed the value you specify.

MAXDATAFILES Clause

Specify the initial sizing of the data files section of the control file at CREATE DATABASE or CREATE CONTROLFILE time. An attempt to add a file whose number is greater than MAXDATAFILES, but less than or equal to DB_FILES, causes the control file to expand automatically so that the data files section can accommodate more files.

The number of data files accessible to your instance is also limited by the initialization parameter DB_FILES.

MAXINSTANCES Clause

Specify the maximum number of instances that can simultaneously have the database mounted and open. This value takes precedence over the value of the initialization parameter INSTANCES. The minimum value is 1. The maximum and default values depend on your operating system.

ARCHIVELOG | NOARCHIVELOG

Specify ARCHIVELOG to archive the contents of redo log files before reusing them. This clause prepares for the possibility of media recovery as well as instance or system failure recovery.

If you omit both the ARCHIVELOG clause and NOARCHIVELOG clause, then Oracle Database chooses NOARCHIVELOG mode by default. After creating the control file, you can change between ARCHIVELOG mode and NOARCHIVELOG mode with the ALTER DATABASE statement.

FORCE LOGGING

Use this clause to put the database into FORCE LOGGING mode after control file creation. When the database is in this mode, Oracle Database logs all changes in the database except changes to temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any NOLOGGING or FORCE LOGGING settings you specify for individual tablespaces and any NOLOGGING settings you specify for individual database objects. If you omit this clause, then the database will not be in FORCE LOGGING mode after the control file is created.

> **Note:**
>
> FORCE LOGGING mode can have performance effects. Refer to *Oracle Database Administrator's Guide* for information on when to use this setting.

SET STANDBY NOLOGGING FOR DATA AVAILABILITY | LOAD PERFORMANCE

SET STANDBY NOLOGGING

The SET STANDBY NOLOGGING disables logging on the standby. You can specify it in two modes:

- **SET STANDBY NOLOGGING FOR DATA AVAILABILITY** guarantees full data replication to the standby database. The primary and standby databases are synchronized during the load. In cases of network congestion the primary database will throttle its load.
- **SET STANDBY NOLOGGING FOR LOAD PERFORMANCE** to maintain speed of primary database load and synchronize with the standby later.

Restrictions On SET STANDBY NOLOGGING

The `SET STANDBY NOLOGGING` clause cannot be used at the same time as `FORCE LOGGING`.

character_set_clause

If you specify a character set, then Oracle Database reconstructs character set information in the control file. If media recovery of the database is subsequently required, then this information will be available before the database is open, so that tablespace names can be correctly interpreted during recovery. This clause is required only if you are using a character set other than the default, which depends on your operating system. Oracle Database prints the current database character set to the alert log in `$ORACLE_HOME/log` during startup.

If you are re-creating your control file and you are using Recovery Manager for tablespace recovery, and if you specify a different character set from the one stored in the data dictionary, then tablespace recovery will not succeed. However, at database open, the control file character set will be updated with the correct character set from the data dictionary.

You cannot modify the character set of the database with this clause.

> **See Also:**
>
> *Oracle Database Backup and Recovery User's Guide* for more information on tablespace recovery

Examples

Creating a Controlfile: Example

This statement re-creates a control file. In this statement, database `demo` was created with the WE8DEC character set. The example uses the word *`path`* where you would normally insert the path on your system to the appropriate Oracle Database directories.

```
STARTUP NOMOUNT

CREATE CONTROLFILE REUSE DATABASE "demo" NORESETLOGS NOARCHIVELOG
    MAXLOGFILES 32
    MAXLOGMEMBERS 2
    MAXDATAFILES 32
    MAXINSTANCES 1
    MAXLOGHISTORY 449
LOGFILE
  GROUP 1 '/path/oracle/dbs/t_log1.f'  SIZE 500K,
  GROUP 2 '/path/oracle/dbs/t_log2.f'  SIZE 500K
# STANDBY LOGFILE
DATAFILE
  '/path/oracle/dbs/t_db1.f',
  '/path/oracle/dbs/dbu19i.dbf',
  '/path/oracle/dbs/tbs_11.f',
  '/path/oracle/dbs/smundo.dbf',
  '/path/oracle/dbs/demo.dbf'
```

```
CHARACTER SET WE8DEC
;
```

CREATE DATABASE

> **Note:**
>
> This statement prepares a database for initial use and erases any data currently in the specified files. Use this statement only when you understand its ramifications.

> **Note:**
>
> In this release of Oracle Database and in subsequent releases, several enhancements are being made to ensure the security of default database user accounts. You can find a security checklist for this release in *Oracle Database Security Guide*. Oracle recommends that you read this checklist and configure your database accordingly.

Purpose

Use the `CREATE DATABASE` statement to create a database, making it available for general use.

This statement erases all data in any specified data files that already exist in order to prepare them for initial database use. If you use the statement on an existing database, then all data in the data files is lost.

After creating the database, this statement mounts it in either exclusive or parallel mode, depending on the value of the `CLUSTER_DATABASE` initialization parameter and opens it, making it available for normal use. You can then create tablespaces for the database.

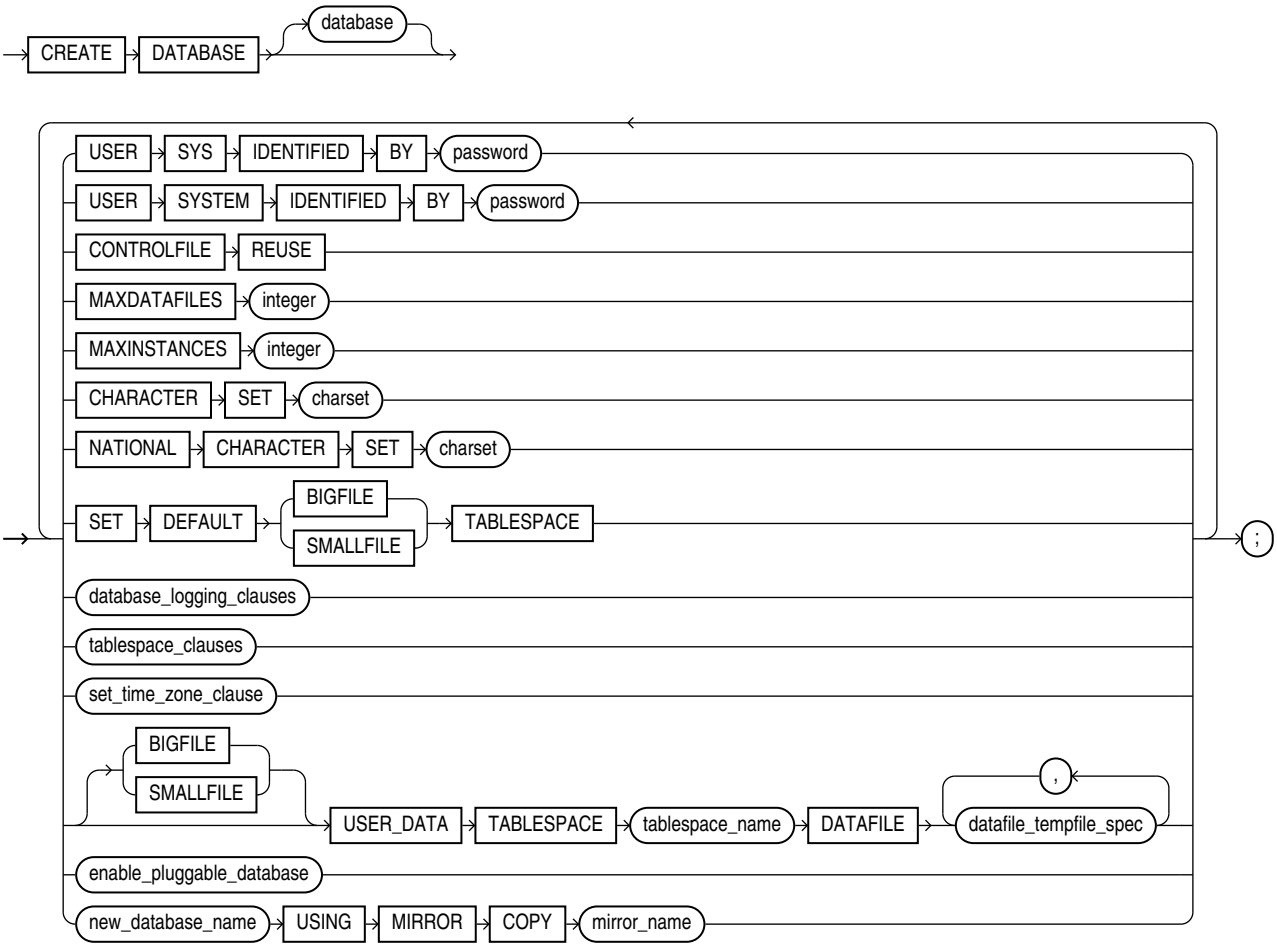
> **See Also:**
>
> - ALTER DATABASE for information on modifying a database
> - *Oracle Database Java Developer's Guide* for information on creating an Oracle Java virtual machine
> - CREATE TABLESPACE for information on creating tablespaces

Prerequisites

To create a database, you must have the `SYSDBA` system privilege. An initialization parameter file with the name of the database to be created must be available, and you must be in `STARTUP NOMOUNT` mode.

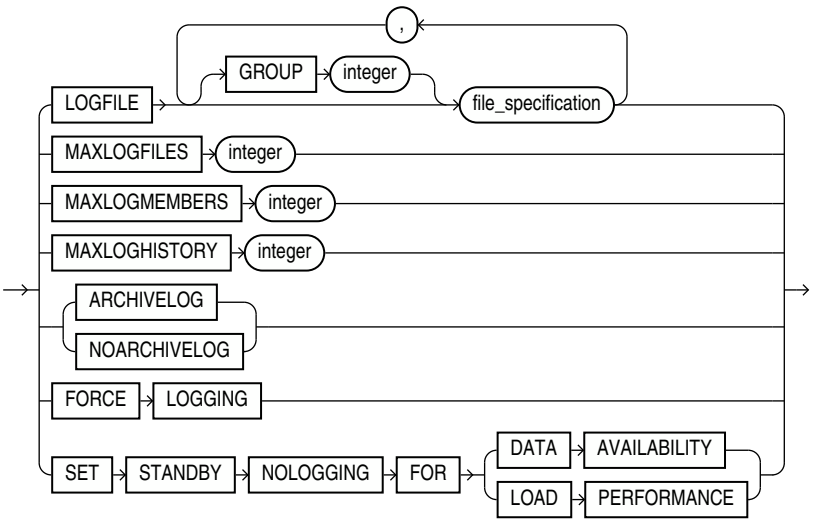
Syntax

***create_database*::=**



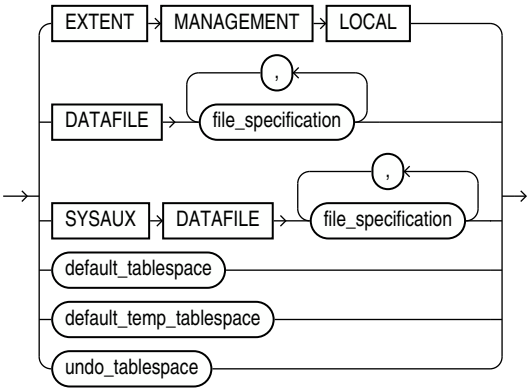
(*database_logging_clauses*::=, *tablespace_clauses*::=, *set_time_zone_clause*::=, *datafile_tempfile_spec*::=, *enable_pluggable_database*::=)

***database_logging_clauses*::=**



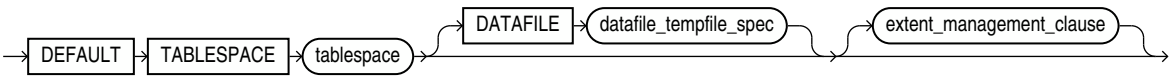
(*file_specification*::=)

***tablespace_clauses*::=**

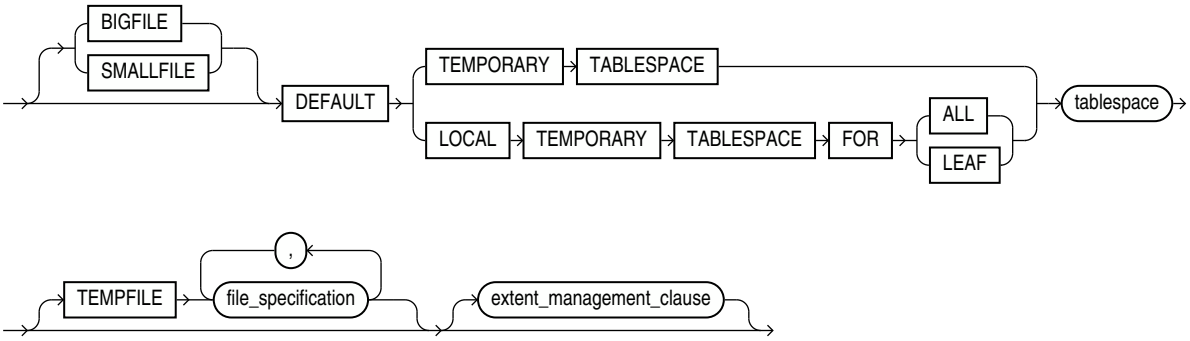


(*file_specification*::=, *default_tablespace*::=, *default_temp_tablespace*::=, *undo_tablespace*::=, *undo_tablespace*::=)

***default_tablespace*::=**

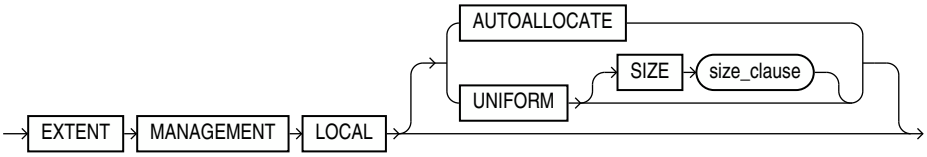


***default_temp_tablespace*::=**



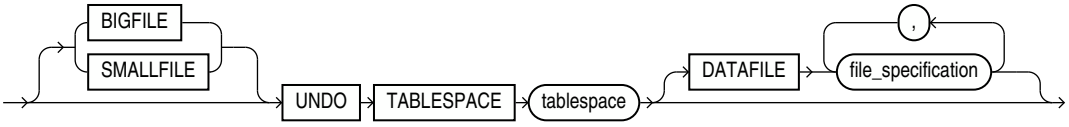
(*file_specification*::=)

***extent_management_clause*::=**



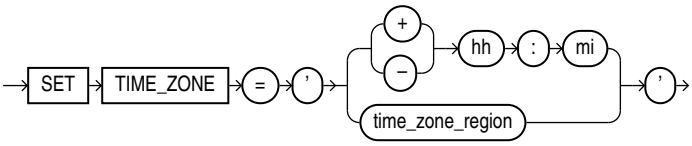
(*size_clause*::=)

***undo_tablespace*::=**

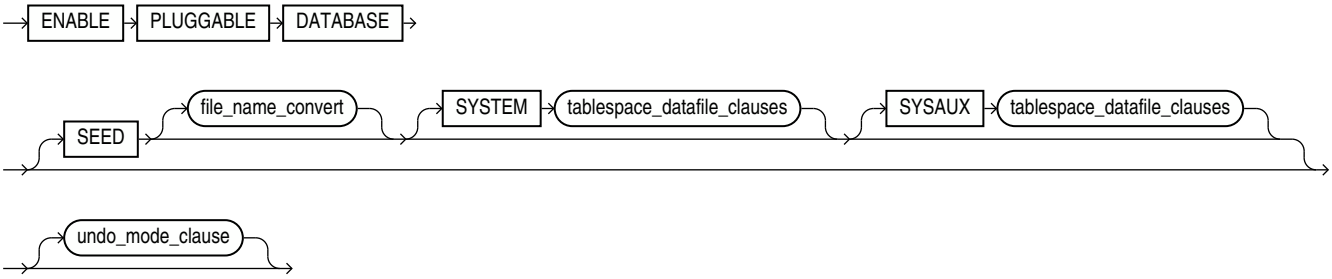


(*file_specification*::=)

***set_time_zone_clause*::=**

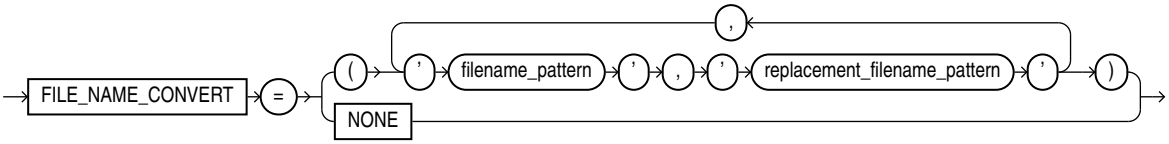


***enable_pluggable_database*::=**

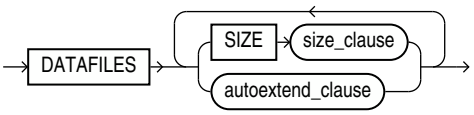


(*tablespace_datafile_clauses*::=, *undo_mode_clause*::=)

***file_name_convert*::=**

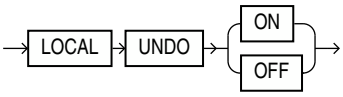


***tablespace_datafile_clauses*::=**



(*size_clause*::=, *autoextend_clause*::=)

***undo_mode_clause*::=**



Semantics

database

Specify the name of the database to be created. The name must match the value of the `DB_NAME` initialization parameter. The name can be up to 8 bytes long and can contain only ASCII characters. The following characters are valid in a database name: alphanumeric characters, underscore (_), number sign (#), and dollar sign ($). No other characters are valid. The database name must start with an alphabetic character. Oracle Database writes this name into the control file. If you subsequently issue an `ALTER DATABASE` statement that explicitly specifies a database name, then Oracle Database verifies that name with the name in the control file.

The database name is case insensitive and is stored in uppercase ASCII characters. If you specify the database name as a quoted identifier, then the quotation marks are silently ignored.

> **Note:**
>
> You cannot use special characters from European or Asian character sets in a database name. For example, characters with umlauts are not allowed.

If you omit the database name from a `CREATE DATABASE` statement, then Oracle Database uses the name specified by the initialization parameter `DB_NAME`. The `DB_NAME` initialization parameter must be set in the database initialization parameter file, and if you specify a different name from the value of that parameter, then the database returns an error. Refer to "Database Object Naming Rules " for additional rules to which database names should adhere.

USER SYS ..., USER SYSTEM ...

Use these clauses to establish passwords for the `SYS` and `SYSTEM` users. These clauses are not mandatory in this release. However, if you specify either clause, then you must specify both clauses.

If you do not specify these clauses, then Oracle Database creates the default password `change_on_install` for user `SYS` . You can change this password later with the `ALTER USER` statement.

> **See Also:**
>
> ALTER USER

CONTROLFILE REUSE Clause

Specify `CONTROLFILE REUSE` to reuse existing control files identified by the initialization parameter `CONTROL_FILES`, overwriting any information they currently contain. Normally you use this clause only when you are re-creating a database, rather than creating one for the first time. When you create a database for the first time, Oracle Database creates a control file in the default destination, which is dependent on the value or several initialization parameters. See `CREATE CONTROLFILE`, "Semantics".

You cannot use this clause if you also specify a parameter value that requires that the control file be larger than the existing files. These parameters are `MAXLOGFILES`, `MAXLOGMEMBERS`, `MAXLOGHISTORY`, `MAXDATAFILES`, and `MAXINSTANCES`.

If you omit this clause and any of the files specified by `CONTROL_FILES` already exist, then the database returns an error.

MAXDATAFILES Clause

Specify the initial sizing of the data files section of the control file at `CREATE DATABASE` or `CREATE CONTROLFILE` time. An attempt to add a file whose number is greater than `MAXDATAFILES`, but less than or equal to `DB_FILES`, causes the Oracle Database control file to expand automatically so that the data files section can accommodate more files.

The number of data files accessible to your instance is also limited by the initialization parameter DB_FILES.

MAXINSTANCES Clause

Specify the maximum number of instances that can simultaneously have this database mounted and open. This value takes precedence over the value of initialization parameter INSTANCES. The minimum value is 1. The maximum value is 1055. The default depends on your operating system.

CHARACTER SET Clause

Specify the character set the database uses to store data. The supported character sets and default value of this parameter depend on your operating system.

Restriction on CHARACTER SET

You cannot specify the AL16UTF16 character set as the database character set.

> **See Also:**
>
> *Oracle Database Globalization Support Guide* for more information about choosing a character set

NATIONAL CHARACTER SET Clause

Specify the national character set used to store data in columns specifically defined as NCHAR, NCLOB, or NVARCHAR2. Valid values are AL16UTF16 and UTF8. The default is AL16UTF16.

> **See Also:**
>
> *Oracle Database Globalization Support Guide* for information on Unicode data type support

SET DEFAULT TABLESPACE Clause

Use this clause to determine the default type of subsequently created tablespaces and of the SYSTEM and SYSAUX tablespaces. Specify either BIGFILE or SMALLFILE to set the default type of subsequently created tablespaces as a bigfile or smallfile tablespace, respectively.

- A **bigfile tablespace** contains only one data file or temp file, which can contain up to approximately 4 billion (2^{32}) blocks. The maximum size of the single data file or temp file is 128 terabytes (TB) for a tablespace with 32K blocks and 32TB for a tablespace with 8K blocks.
- A **smallfile tablespace** is a traditional Oracle tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million (2^{22}) blocks.

If you omit this clause, then Oracle Database creates bigfile tablespaces by default for SYSAUX, SYSTEM, and USER tablespaces .

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for more information about bigfile tablespaces
> - "Setting the Default Type of Tablespaces: Example" for an example using this syntax

database_logging_clauses

Use the *database_logging_clauses* to determine how Oracle Database will handle redo log files for this database.

LOGFILE Clause

Specify one or more files to be used as redo log files. Use the *redo_log_file_spec* form of *file_specification* to create regular redo log files in an operating system file system or to create Oracle ASM disk group redo log files. When using a form of *ASM_filename*, you cannot specify the *autoextend_clause* of *redo_log_file_spec*.

The *redo_log_file_spec* clause specifies a redo log file group containing one or more redo log file members (copies). All redo log files specified in a CREATE DATABASE statement are added to redo log thread number 1.

> **See Also:**
>
> *file_specification* for a full description of this clause

If you omit the LOGFILE clause, then Oracle Database creates an Oracle-managed log file member in the default destination, which is one of the following locations (in order of precedence):

- If DB_CREATE_ONLINE_LOG_DEST_*n* is set, then the database creates a log file member in each directory specified, up to the value of the MAXLOGMEMBERS initialization parameter.
- If the DB_CREATE_ONLINE_LOG_DEST_*n* parameter is not set, but both the DB_CREATE_FILE_DEST and DB_RECOVERY_FILE_DEST initialization parameters are set, then the database creates one Oracle-managed log file member in each of those locations. The log file in the DB_CREATE_FILE_DEST destination is the first member.
- If only the DB_CREATE_FILE_DEST initialization parameter is specified, then Oracle Database creates a log file member in that location.
- If only the DB_RECOVERY_FILE_DEST initialization parameter is specified, then Oracle Database creates a log file member in that location.

In all these cases, the parameter settings must correctly specify operating system filenames or creation form Oracle ASM filenames, as appropriate.

If no values are set for any of these parameters, then the database creates a log file in the default location for the operating system on which the database is running. This log file is not an Oracle Managed File.

GROUP *integer*

Specify the number that identifies the redo log file group. The value of *integer* can range from 1 to the value of the MAXLOGFILES parameter. A database must have at least two redo log file groups. You cannot specify multiple redo log file groups having the same GROUP value. If you omit this parameter, then Oracle Database generates its value automatically. You can examine the GROUP value for a redo log file group through the dynamic performance view V$LOG.

MAXLOGFILES Clause

Specify the maximum number of redo log file groups that can ever be created for the database. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The default, minimum, and maximum values depend on your operating system.

MAXLOGMEMBERS Clause

Specify the maximum number of members, or copies, for a redo log file group. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The minimum value is 1. The maximum and default values depend on your operating system.

MAXLOGHISTORY Clause

This parameter is useful only if you are using Oracle Database in ARCHIVELOG mode with Oracle Real Application Clusters (Oracle RAC). Specify the maximum number of archived redo log files for automatic media recovery of Oracle RAC. The database uses this value to determine how much space to allocate in the control file for the names of archived redo log files. The minimum value is 0. The default value is a multiple of the MAXINSTANCES value and depends on your operating system. The maximum value is limited only by the maximum size of the control file.

ARCHIVELOG

Specify ARCHIVELOG if you want the contents of a redo log file group to be archived before the group can be reused. This clause prepares for the possibility of media recovery.

NOARCHIVELOG

Specify NOARCHIVELOG if the contents of a redo log file group need not be archived before the group can be reused. This clause does not allow for the possibility of media recovery.

The default is NOARCHIVELOG mode. After creating the database, you can change between ARCHIVELOG mode and NOARCHIVELOG mode with the ALTER DATABASE statement.

FORCE LOGGING

Use this clause to put the database into FORCE LOGGING mode. Oracle Database will log all changes in the database except for changes in temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any NOLOGGING or FORCE LOGGING settings you specify for individual tablespaces and any NOLOGGING settings you specify for individual database objects.

FORCE LOGGING mode is persistent across instances of the database. If you shut down and restart the database, then the database is still in FORCE LOGGING mode. However, if you re-create the control file, then Oracle Database will take the database out of FORCE LOGGING mode unless you specify FORCE LOGGING in the CREATE CONTROLFILE statement.

> **Note:**
>
> `FORCE LOGGING` mode can have performance effects. Refer to *Oracle Database Administrator's Guide* for information on when to use this setting.

> **See Also:**
>
> CREATE CONTROLFILE

SET STANDBY NOLOGGING FOR DATA AVAILABILITY | LOAD PERFORMANCE

The `SET STANDBY NOLOGGING` disables logging on the standby. You can specify it in two modes:

- **SET STANDBY NOLOGGING FOR DATA AVAILABILITY** guarantees full data replication to the standby database. The primary and standby databases are synchronized during the load. In cases of network congestion the primary database will throttle its load.
- **SET STANDBY NOLOGGING FOR LOAD PERFORMANCE** to maintain speed of primary database load and synchronize with the standby later.

Restrictions SET STANDBY NOLOGGING

The`SET STANDBY NOLOGGING` clause cannot be used at the same time as `FORCE LOGGING`.

tablespace_clauses

Use the tablespace clauses to configure the `SYSTEM` and `SYSAUX` tablespaces and to specify a default temporary tablespace and an undo tablespace.

extent_management_clause

Use this clause to create a locally managed `SYSTEM` tablespace. If you omit this clause, then the `SYSTEM` tablespace will be dictionary managed.

> **Note:**
>
> When you create a locally managed `SYSTEM` tablespace, you cannot change it to be dictionary managed, nor can you create any other dictionary-managed tablespaces in this database.

If you specify this clause, then the database must have a default temporary tablespace, because a locally managed `SYSTEM` tablespace cannot store temporary segments.

- If you specify `EXTENT MANAGEMENT LOCAL` but you do not specify the `DATAFILE` clause, then you can omit the *`default_temp_tablespace`* clause. Oracle Database will create a default temporary tablespace called `TEMP` with one data file of size 10M with autoextend disabled.
- If you specify both `EXTENT MANAGEMENT LOCAL` and the `DATAFILE` clause, then you must also specify the *`default_temp_tablespace`* clause and explicitly specify a temp file for that temporary tablespace.

If you have opened the instance in automatic undo mode, similar requirements exist for the database undo tablespace:

- If you specify `EXTENT MANAGEMENT LOCAL` but you do not specify the `DATAFILE` clause, then you can omit the *undo_tablespace* clause. Oracle Database will create an undo tablespace named `SYS_UNDOTBS`.
- If you specify both `EXTENT MANAGEMENT LOCAL` and the `DATAFILE` clause, then you must also specify the *undo_tablespace* clause and explicitly specify a data file for that tablespace.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information on locally managed and dictionary-managed tablespaces

DATAFILE Clause

Specify one or more files to be used as data files. All these files become part of the `SYSTEM` tablespace. Use the data *file_tempfile_spec* form of *file_specification* to create regular data files and temp files in an operating system file system or to create Oracle ASM disk group files.

> **Note:**
>
> This clause is optional, as is the `DATAFILE` clause of the *undo_tablespace* clause. Therefore, to avoid ambiguity, if your intention is to specify a data file for the `SYSTEM` tablespace with this clause, then do *not* specify it immediately after an *undo_tablespace* clause that does not include the optional `DATAFILE` clause. If you do so, then Oracle Database will interpret the `DATAFILE` clause to be part of the *undo_tablespace* clause.

The syntax for specifying data files for the `SYSTEM` tablespace is the same as that for specifying data files during tablespace creation using the `CREATE TABLESPACE` statement, whether you are storing files using Oracle ASM or in a file system.

> **See Also:**
>
> CREATE TABLESPACE for information on specifying data files

If you are running the database in automatic undo mode and you specify a data file name for the `SYSTEM` tablespace, then Oracle Database expects to generate data files for all tablespaces. Oracle Database does this automatically if you are using Oracle Managed Files—you have set a value for the `DB_CREATE_FILE_DEST` initialization parameter. However, if you are not using Oracle Managed Files and you specify this clause, then you must also specify the *undo_tablespace* clause and the *default_temp_tablespace* clause.

If you omit this clause, then:

- If the DB_CREATE_FILE_DEST initialization parameter is set, then Oracle Database creates a 100 MB Oracle-managed data file with a system-generated name in the default file destination specified in the parameter.
- If the DB_CREATE_FILE_DEST initialization parameter is not set, then Oracle Database creates one data file whose name and size depend on your operating system.

> **See Also:**
>
> *file_specification* for syntax

SYSAUX Clause

Oracle Database creates both the SYSTEM and SYSAUX tablespaces as part of every database. Use this clause if you are not using Oracle Managed Files and you want to specify one or more data files for the SYSAUX tablespace.

You must specify this clause if you have specified one or more data files for the SYSTEM tablespace using the DATAFILE clause. If you are using Oracle Managed Files and you omit this clause, then the database creates the SYSAUX data files in the default location set up for Oracle Managed Files.

If you have enabled Oracle Managed Files and you omit the SYSAUX clause, then the database creates the SYSAUX tablespace as an online, permanent, locally managed tablespace with one data file of 100 MB, with logging enabled and automatic segment-space management.

The syntax for specifying data files for the SYSAUX tablespace is the same as that for specifying data files during tablespace creation using the CREATE TABLESPACE statement, whether you are storing files using Oracle ASM or in a file system.

> **See Also:**
>
> - CREATE TABLESPACE for information on creating the SYSAUX tablespace during database upgrade and for information on specifying data files in a tablespace
> - *Oracle Database Administrator's Guide* for more information on creating the SYSAUX tablespace

default_tablespace

Specify this clause to create a default permanent tablespace for the database. Oracle Database creates a smallfile tablespace and subsequently will assign to this tablespace any non-SYSTEM users for whom you do not specify a different permanent tablespace. If you do not specify this clause, then the SYSTEM tablespace is the default permanent tablespace for non-SYSTEM users.

The DATAFILE clause and *extent_management_clause* have the same semantics they have in a CREATE TABLESPACE statement. Refer to "DATAFILE | TEMPFILE Clause" and *extent_management_clause* for information on these clauses.

default_temp_tablespace

Use this clause to create a default shared temporary tablespace or a default local temporary tablespace. Oracle Database will assign to these temporary tablespaces any users for whom you do not specify different temporary tablespaces.

- Specify `DEFAULT TEMPORARY TABLESPACE` to create a default shared temporary tablespace for the database. Shared temporary tablespaces were available in prior releases of Oracle Database and were called "temporary tablespaces." Elsewhere in this guide, the term "temporary tablespace" refers to a shared temporary tablespace unless specified otherwise. If you do not specify this clause, and if the database does not create a default shared temporary tablespace automatically in the process of creating a locally managed `SYSTEM` tablespace, then the `SYSTEM` tablespace is the default shared temporary tablespace.
- Starting with Oracle Database 12*c* Release 2 (12.2), you can specify `DEFAULT LOCAL TEMPORARY TABLESPACE` to create a default local temporary tablespace. Local temporary tablespaces are useful for Oracle Real Application Clusters and Oracle Flex Clusters. They store a separate, nonshared temp file for each database instance, which can improve I/O performance. A local temporary tablespace must be a `BIGFILE` tablespace.
  - Specify `FOR ALL` to instruct the database to create separate, nonshared temp files for all HUB and LEAF nodes.
  - Specify `FOR LEAF` to instruct the database to create separate nonshared temp files for only LEAF nodes. If you specify this clause, then HUB nodes will use the default shared temporary tablespace. For SQL operations that span both HUB and LEAF nodes, HUB nodes will use the default shared temporary tablespace and LEAF nodes will use the default local temporary tablespace.

  If you do not create a local temporary tablespace, then HUB and LEAF nodes will use the default shared temporary tablespace.

Specify `BIGFILE` or `SMALLFILE` to determine whether the default temporary tablespace is a bigfile or smallfile tablespace. These clauses have the same semantics as in the "SET DEFAULT TABLESPACE Clause ".

The `TEMPFILE` clause part of this clause is optional if you have enabled Oracle Managed Files by setting the `DB_CREATE_FILE_DEST` initialization parameter. If you have not specified a value for this parameter, then the `TEMPFILE` clause is required. If you have specified `BIGFILE`, then you can specify only one temp file in this clause.

The syntax for specifying temp files for the default temporary tablespace is the same as that for specifying temp files during temporary tablespace creation using the `CREATE TABLESPACE` statement, whether you are storing files using Oracle ASM or in a file system.

The *`extent_management_clause`* clause has the same semantics in `CREATE DATABASE` and `CREATE TABLESPACE` statements. For complete information, refer to the `CREATE TABLESPACE` ... *extent_management_clause* .

> **See Also:**
>
> CREATE TABLESPACE for information on specifying temp files

> **Note:**
>
> On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

Restrictions on Default Temporary Tablespaces

Default temporary tablespaces are subject to the following restrictions:

- You cannot specify the `SYSTEM` tablespace in this clause.
- The default temporary tablespace must have a standard block size.

undo_tablespace

If you have opened the instance in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `AUTO`, which is the default), then you can specify the *`undo_tablespace`* to create a tablespace to be used for undo data. Oracle strongly recommends that you use automatic undo mode. However, if you want undo space management to be handled by way of rollback segments, then you must omit this clause. You can also omit this clause if you have set a value for the `UNDO_TABLESPACE` initialization parameter. If that parameter has been set, and if you specify this clause, then *`tablespace`* must be the same as that parameter value.

- Specify `BIGFILE` if you want the undo tablespace to be a bigfile tablespace. A **bigfile tablespace** contains only one data file, which can be up to 8 exabytes (8 million terabytes) in size.

  Tablespaces `SYSAUX`, `SYSTEM`, and `USER` are `BIGFILE` by default.
- Specify `SMALLFILE` if you want the undo tablespace to be a smallfile tablespace. A **smallfile tablespace** is a traditional Oracle Database tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million (2^{22}) blocks.
- The `DATAFILE` clause part of this clause is optional if you have enabled Oracle Managed Files by setting the `DB_CREATE_FILE_DEST` initialization parameter. If you have not specified a value for this parameter, then the `DATAFILE` clause is required. If you have specified `BIGFILE`, then you can specify only one data file in this clause.

The syntax for specifying data files for the undo tablespace is the same as that for specifying data files during tablespace creation using the `CREATE TABLESPACE` statement, whether you are storing files using Oracle ASM or in a file system.

> **See Also:**
>
> CREATE TABLESPACE for information on specifying data files

If you specify this clause, then Oracle Database creates an undo tablespace named *tablespace*, creates the specified data file(s) as part of the undo tablespace, and assigns this tablespace as the undo tablespace of the instance. Oracle Database will manage undo data using this undo tablespace. The DATAFILE clause of this clause has the same behavior as described in "DATAFILE Clause".

If you have specified a value for the UNDO_TABLESPACE initialization parameter in your initialization parameter file before mounting the database, then you must specify the same name in this clause. If these names differ, then Oracle Database will return an error when you open the database.

If you omit this clause, then Oracle Database creates a default database with a default smallfile undo tablespace named SYS_UNDOTBS and assigns this default tablespace as the undo tablespace of the instance. This undo tablespace allocates disk space from the default files used by the CREATE DATABASE statement, and it has an initial extent of 10M. Oracle Database handles the system-generated data file as described in "DATAFILE Clause". If Oracle Database is unable to create the undo tablespace, then the entire CREATE DATABASE operation fails.

See Also:

- *Oracle Database Administrator's Guide* for information on automatic undo management and undo tablespaces
- CREATE TABLESPACE for information on creating an undo tablespace after database creation

set_time_zone_clause

Use the SET TIME_ZONE clause to set the time zone of the database. You can specify the time zone in two ways:

- By specifying a displacement from UTC (Coordinated Universal Time—formerly Greenwich Mean Time). The valid range of *hh:mi* is -12:00 to +14:00.
- By specifying a time zone region. To see a listing of valid time zone region names, query the TZNAME column of the V$TIMEZONE_NAMES dynamic performance view.

Note:

Oracle recommends that you set the database time zone to UTC (0:00). Doing so can improve performance, especially across databases, as no conversion of time zones will be required.

See Also:

Oracle Database Reference for information on the dynamic performance views

Oracle Database normalizes all TIMESTAMP WITH LOCAL TIME ZONE data to the time zone of the database when the data is stored on disk. If you do not specify the SET TIME_ZONE clause, then

the database uses the operating system time zone of the server. If the operating system time zone is not a valid Oracle Database time zone, then the database time zone defaults to UTC.

USER_DATA TABLESPACE Clause

This clause lets you create a tablespace that is used for storing user data and database options such as Oracle XML DB.

If you specify this clause when creating a multitenant container database (CDB), then the tablespace is created as part of the seed. Pluggable databases (PDBs) subsequently created using the seed will include this tablespace and its data file. The tablespace and data file specified in this clause are not used by the root.

Specify `BIGFILE` or `SMALLFILE` to determine whether the tablespace is a bigfile or smallfile tablespace. If you omit these clauses, then Oracle Database creates a tablespace of the type that you specify with the `SET DEFAULT TABLESPACE` clause. If you do not specify the `SET DEFAULT TABLESPACE` clause, then Oracle Database creates a smallfile tablespace. These clauses have the same semantics as in the "SET DEFAULT TABLESPACE Clause ".

Use the *`datafile_tempfile_spec`* clause to specify one or more data files for the tablespace. Refer to datafile_tempfile_spec for the full semantics of this clause.

enable_pluggable_database

Starting with Oracle Database 21c, the `ENABLE_PLUGGABLE_DATABASE` initialization parameter is set to `TRUE` by default. If you set the `ENABLE_PLUGGABLE_DATABASE` initialization parameter to `FALSE`, the command will fail.

The `CREATE DATABASE` *`enable_pluggable_database`* statement creates a CDB that contains a root and a seed container. You then create PDBs in the CDB by using the `CREATE PLUGGABLE DATABASE` statement.

> **See Also:**
>
> - Creating and configuring a cdb.
> - CREATE PLUGGABLE DATABASE
> - "Creating a CDB: Example"

file_name_convert

Use the *`file_name_convert`* clause to determine how the database generates the names of files (such as data files and wallet files) associated with the seed by using the names of files associated with the root.

- For *`filename_pattern`*, specify a string found in file names associated with the root.
- For *`replacement_filename_pattern`*, specify a replacement string.

Oracle Database will replace *`filename_pattern`* with *`replacement_filename_pattern`* when generating the names of files associated with the seed.

File name patterns cannot match files or directories managed by Oracle Managed Files.

You can specify `FILE_NAME_CONVERT = NONE`, which is the same as omitting this clause. If you omit this clause, then the database first attempts to use Oracle Managed Files to generate seed file names. If you are not using Oracle Managed Files, then the database uses the

PDB_FILE_NAME_CONVERT initialization parameter to generate file names. If this parameter is not set, then an error occurs.

tablespace_datafile_clauses

Use these clauses to specify attributes for all data files comprising the SYSTEM and SYSAUX tablespaces in the seed PDB. If you do not specify SIZE *size_clause*, then the data file size for a given tablespace will be set to a predetermined fraction of the size of the corresponding root data file. If you do not specify the *autoextend_clause*, then those values are inherited from the root.

Refer to *size_clause* and *autoextend_clause* for the full semantics of these clauses.

undo_mode_clause

This clause lets you specify local undo mode or shared undo mode for the CDB.

- Use LOCAL UNDO ON to specify local undo mode for the CDB. In this mode, every container in the CDB uses local undo.
- Use LOCAL UNDO OFF to specify shared undo mode for the CDB. In this mode, there is one active undo tablespace for a single-instance CDB, or for an Oracle RAC CDB, there is one active undo tablespace for each instance.

If you omit this clause, then the default is LOCAL UNDO OFF.

USING MIRROR COPY

Use this clause to create a database with *new_database_name* using the prepared files of the mirror copy, identified by *mirror_name*.

Examples

Creating a Database: Example

The following statement creates a database and fully specifies each argument:

```
CREATE DATABASE sample
   CONTROLFILE REUSE
   LOGFILE
      GROUP 1 ('diskx:log1.log', 'disky:log1.log') SIZE 50K,
      GROUP 2 ('diskx:log2.log', 'disky:log2.log') SIZE 50K
   MAXLOGFILES 5
   MAXLOGHISTORY 100
   MAXDATAFILES 10
   MAXINSTANCES 2
   ARCHIVELOG
   CHARACTER SET AL32UTF8
   NATIONAL CHARACTER SET AL16UTF16
   DATAFILE
      'disk1:df1.dbf' AUTOEXTEND ON,
      'disk2:df2.dbf' AUTOEXTEND ON NEXT 10M MAXSIZE UNLIMITED
   DEFAULT TEMPORARY TABLESPACE temp_ts
   UNDO TABLESPACE undo_ts
   SET TIME_ZONE = '+02:00';
```

This example assumes that you have enabled Oracle Managed Files by specifying a value for the DB_CREATE_FILE_DEST parameter in your initialization parameter file. Therefore no file specification is needed for the DEFAULT TEMPORARY TABLESPACE and UNDO TABLESPACE clauses.

Creating a CDB: Example

The following statement creates a CDB `newcdb`. The `ENABLE PLUGGABLE DATABASE` clause indicates that a CDB is being created. The CDB will contain a root (`CDB$ROOT`) and a seed (`PDB$SEED`). The `FILE_NAME_CONVERT` clause specifies that names of files for the seed will be generated by replacing `/u01/app/oracle/oradata/newcdb` in the names of files associated with the root with `/u01/app/oracle/oradata/pdbseed`.

```
CREATE DATABASE newcdb
  USER SYS IDENTIFIED BY sys_password
  USER SYSTEM IDENTIFIED BY system_password
  LOGFILE GROUP 1 ('/u01/logs/my/redo01a.log','/u02/logs/my/redo01b.log')
             SIZE 100M BLOCKSIZE 512,
          GROUP 2 ('/u01/logs/my/redo02a.log','/u02/logs/my/redo02b.log')
             SIZE 100M BLOCKSIZE 512,
          GROUP 3 ('/u01/logs/my/redo03a.log','/u02/logs/my/redo03b.log')
             SIZE 100M BLOCKSIZE 512
  MAXLOGHISTORY 1
  MAXLOGFILES 16
  MAXLOGMEMBERS 3
  MAXDATAFILES 1024
  CHARACTER SET AL32UTF8
  NATIONAL CHARACTER SET AL16UTF16
  EXTENT MANAGEMENT LOCAL
  DATAFILE '/u01/app/oracle/oradata/newcdb/system01.dbf'
    SIZE 700M REUSE AUTOEXTEND ON NEXT 10240K MAXSIZE UNLIMITED
  SYSAUX DATAFILE '/u01/app/oracle/oradata/newcdb/sysaux01.dbf'
    SIZE 550M REUSE AUTOEXTEND ON NEXT 10240K MAXSIZE UNLIMITED
  DEFAULT TABLESPACE deftbs
    DATAFILE '/u01/app/oracle/oradata/newcdb/deftbs01.dbf'
    SIZE 500M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED
  DEFAULT TEMPORARY TABLESPACE tempts1
    TEMPFILE '/u01/app/oracle/oradata/newcdb/temp01.dbf'
    SIZE 20M REUSE AUTOEXTEND ON NEXT 640K MAXSIZE UNLIMITED
  UNDO TABLESPACE undotbs1
    DATAFILE '/u01/app/oracle/oradata/newcdb/undotbs01.dbf'
    SIZE 200M REUSE AUTOEXTEND ON NEXT 5120K MAXSIZE UNLIMITED
  ENABLE PLUGGABLE DATABASE
    SEED
    FILE_NAME_CONVERT = ('/u01/app/oracle/oradata/newcdb/',
                         '/u01/app/oracle/oradata/pdbseed/')
    SYSTEM DATAFILES SIZE 125M AUTOEXTEND ON NEXT 10M MAXSIZE UNLIMITED
    SYSAUX DATAFILES SIZE 100M
  USER_DATA TABLESPACE usertbs
    DATAFILE '/u01/app/oracle/oradata/pdbseed/usertbs01.dbf'
    SIZE 200M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED;
```

CREATE DATABASE LINK

Purpose

Use the `CREATE DATABASE LINK` statement to create a database link. A **database link** is a schema object in one database that enables you to access objects on another database. The other database need not be an Oracle Database system. However, to access non-Oracle systems you must use Oracle Heterogeneous Services.

After you have created a database link, you can use it in SQL statements to refer to tables, views, and PL/SQL objects in the other database by appending *`@dblink`* to the table, view, or PL/SQL object name. You can query a table or view in the other database with the `SELECT` statement. You can also access remote tables and views using any `INSERT`, `UPDATE`, `DELETE`, or `LOCK TABLE` statement.

See Also:

- *Oracle Database Development Guide* for information about accessing remote tables or views with PL/SQL functions, procedures, packages, and data types
- *Oracle Database Administrator's Guide* for information on distributed database systems
- *Oracle Database Reference* for descriptions of existing database links in the `ALL_DB_LINKS`, `DBA_DB_LINKS`, and `USER_DB_LINKS` data dictionary views and for information on monitoring the performance of existing links through the `V$DBLINK` dynamic performance view
- ALTER DATABASE LINK for information on altering a database link when the password of a connection or authentication user changes.
- DROP DATABASE LINK for information on dropping existing database links
- INSERT , UPDATE , DELETE , and LOCK TABLE for using links in DML operations

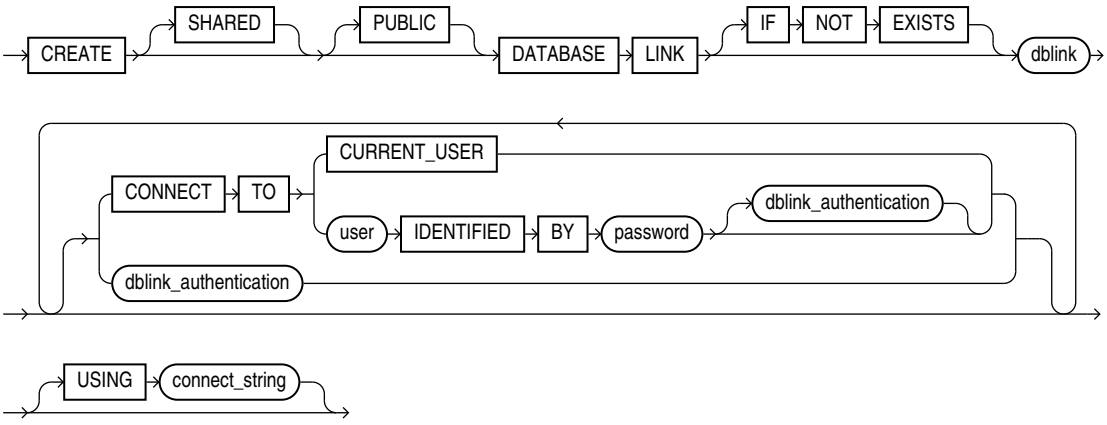
Prerequisites

To create a private database link, you must have the `CREATE DATABASE LINK` system privilege. To create a public database link, you must have the `CREATE PUBLIC DATABASE LINK` system privilege. Also, you must have the `CREATE SESSION` system privilege on the remote Oracle Database.

Oracle Net must be installed on both the local and remote Oracle Databases.

Syntax

***create_database_link*::=**



(*dblink*::=)

***dblink_authentication*::=**

Semantics

SHARED

Specify `SHARED` to create a database link that can be shared by multiple sessions using a single network connection from the source database to the target database. In a shared server configuration, shared database links can keep the number of connections into the remote database from becoming too large. Shared links are typically also public database links. However, a shared private database link can be useful when many clients access the same local schema, and therefore use the same private database link.

In a shared database link, multiple sessions in the source database share the same connection to the target database. Once a session is established on the target database, that session is disassociated from the connection, to make the connection available to another session on the source database. To prevent an unauthorized session from attempting to connect through the database link, when you specify `SHARED` you must also specify the *`dblink_authentication`* clause for the users authorized to use the database link.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information about shared database links

PUBLIC

Specify `PUBLIC` to create a public database link visible to all users. If you omit this clause, then the database link is private and is available only to you.

The data accessible on the remote database depends on the identity the database link uses when connecting to the remote database:

- If you specify `CONNECT TO` *`user`* `IDENTIFIED BY` *`password`*, then the database link connects with the specified user and password.
- If you specify `CONNECT TO CURRENT_USER`, then the database link connects with the user in effect based on the scope in which the link is used.
- If you omit both of those clauses, then the database link connects to the remote database as the locally connected user.

> **See Also:**
>
> "Defining a Public Database Link: Example"

dblink

Specify the complete or partial name of the database link. If you specify only the database name, then Oracle Database implicitly appends the database domain of the local database.

Use only ASCII characters for *`dblink`*. Multibyte characters are not supported. The database link name is case insensitive and is stored in uppercase ASCII characters. If you specify the database name as a quoted identifier, then the quotation marks are silently ignored.

If the value of the GLOBAL_NAMES initialization parameter is TRUE, then the database link must have the same name as the database to which it connects. If the value of GLOBAL_NAMES is FALSE, and if you have changed the global name of the database, then you can specify the global name.

The maximum number of database links that can be open in one session or one instance of an Oracle RAC configuration depends on the value of the OPEN_LINKS and OPEN_LINKS_PER_INSTANCE initialization parameters.

Restriction on Creating Database Links

You cannot create a database link in another user's schema, and you cannot qualify *dblink* with the name of a schema. Periods are permitted in names of database links, so Oracle Database interprets the entire name, such as ralph.linktosales, as the name of a database link in your schema rather than as a database link named linktosales in the schema ralph.

> **See Also:**
>
> - "References to Objects in Remote Databases " for guidelines for naming database links
> - *Oracle Database Reference* for information on the GLOBAL_NAMES, OPEN_LINKS, and OPEN_LINKS_PER_INSTANCE initialization parameters
> - "RENAME GLOBAL_NAME Clause" (an ALTER DATABASE clause) for information on changing the database global name

IF NOT EXISTS

Specifying IF NOT EXISTS has the following effects:

- If the database link does not exist, a new database link is created at the end of the statement.
- If the database link exists, this is the database link you have at the end of the statement. A new one is not created because the older database link is detected.

Using IF EXISTS with CREATE results in ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.

CONNECT TO Clause

The CONNECT TO clause lets you specify the user and credentials, if any, to be used to connect to the remote database.

CURRENT_USER Clause

Specify CURRENT_USER to create a **current user database link**. The current user must be a global user with a valid account on the remote database.

If the database link is used directly rather than from within a stored object, then the current user is the same as the connected user.

When executing a stored object (such as a procedure, view, or trigger) that initiates a database link, CURRENT_USER is the name of the user that owns the stored object, and not the name of the user that called the object. For example, if the database link appears inside procedure scott.p (created by scott), and user jane calls procedure scott.p, then the current user is scott.

However, if the stored object is an invoker-rights function, procedure, or package, then the invoker's authorization ID is used to connect as a remote user. For example, if the privileged database link appears inside procedure `scott.p` (an invoker-rights procedure created by `scott`), and user Jane calls procedure `scott.p`, then `CURRENT_USER` is `jane` and the procedure executes with Jane's privileges.

> **See Also:**
>
> - CREATE FUNCTION for more information on invoker-rights functions
> - "Defining a CURRENT_USER Database Link: Example"

user* IDENTIFIED BY *password

Specify the user name and password used to connect to the remote database using a **fixed user database link**. If you omit this clause, then the database link uses the user name and password of each user who is connected to the database. This is called a **connected user database link**.

You can set the password to a maximum length of 1024 bytes.

> **See Also:**
>
> "Defining a Fixed-User Database Link: Example"

dblink_authentication

You can specify this clause only if you are creating a shared database link—that is, you have specified the `SHARED` clause. Specify the username and password on the target instance. This clause authenticates the user to the remote server and is required for security. The specified username and password must be a valid username and password on the remote instance. The username and password are used only for authentication. No other operations are performed on behalf of this user.

CONNECT WITH Clause

Use `CONNECT WITH` to specify the credential object that stores the username and password to connect to the remote database.

You can create, update, or drop the credential using the `DBMS_CREDENTIAL` package.

You can use a credential object belonging to another user, if that user has granted you execute privileges on the credential object.

USING '*connect string*'

Specify the service name of a remote database. If you specify only the database name, then Oracle Database implicitly appends the database domain to the connect string to create a complete service name. Therefore, if the database domain of the remote database is different from that of the current database, then you must specify the complete service name.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information on specifying remote databases

Examples

The examples that follow assume two databases, one with the database name `local` and the other with the database name `remote`. The examples use the Oracle Database domain. Your database domain will be different.

Defining a Public Database Link: Example

The following statement defines a shared public database link named `remote` that refers to the database specified by the service name `remote`:

```
CREATE PUBLIC DATABASE LINK remote
   USING 'remote';
```

This database link allows user `hr` on the `local` database to update a table on the `remote` database (assuming `hr` has appropriate privileges):

```
UPDATE employees@remote
   SET salary=salary*1.1
   WHERE last_name = 'Baer';
```

Defining a Fixed-User Database Link: Example

In the following statement, user `hr` on the `remote` database defines a fixed-user database link named `local` to the `hr` schema on the `local` database:

```
CREATE DATABASE LINK local
   CONNECT TO hr IDENTIFIED BY password
   USING 'local';
```

After this database link is created, `hr` can query tables in the schema `hr` on the `local` database in this manner:

```
SELECT * FROM employees@local;
```

User `hr` can also use DML statements to modify data on the `local` database:

```
INSERT INTO employees@local
   (employee_id, last_name, email, hire_date, job_id)
   VALUES (999, 'Claus', 'sclaus@example.com', SYSDATE, 'SH_CLERK');

UPDATE jobs@local SET min_salary = 3000
   WHERE job_id = 'SH_CLERK';

DELETE FROM employees@local
   WHERE employee_id = 999;
```

Using this fixed database link, user hr on the `remote` database can also access tables owned by other users on the same database. This statement assumes that user `hr` has the `READ` or `SELECT` privilege on the `oe.customers` table. The statement connects to the user `hr` on the `local` database and then queries the `oe.customers` table:

```
SELECT * FROM oe.customers@local;
```

Defining a CURRENT_USER Database Link: Example

The following statement defines a current-user database link to the `remote` database, using the entire service name as the link name:

```
CREATE DATABASE LINK remote.us.example.com
   CONNECT TO CURRENT_USER
   USING 'remote';
```

The user who issues this statement must be a global user registered with the LDAP directory service.

You can create a synonym to hide the fact that a particular table is on the `remote` database. The following statement causes all future references to `emp_table` to access the `employees` table owned by `hr` on the `remote` database:

```
CREATE SYNONYM emp_table
   FOR oe.employees@remote.us.example.com;
```

CREATE DIMENSION

Purpose

Use the `CREATE DIMENSION` statement to create a **dimension**. A dimension defines a parent-child relationship between pairs of column sets, where all the columns of a column set must come from the same table. However, columns in one column set (called a **level**) can come from a different table than columns in another set. The optimizer uses these relationships with materialized views to perform **query rewrite**. The SQL Access Advisor uses these relationships to recommend creation of specific materialized views.

> **Note:**
>
> Oracle Database does not automatically validate the relationships you declare when creating a dimension. To validate the relationships specified in the *`hierarchy_clause`* and the *`dimension_join_clause`* of `CREATE DIMENSION`, you must run the `DBMS_OLAP.VALIDATE_DIMENSION` procedure.

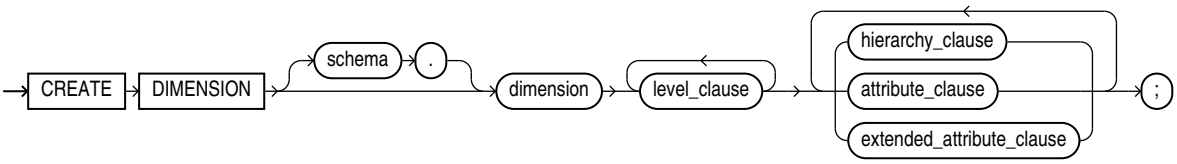
> **See Also:**
>
> - CREATE MATERIALIZED VIEW for more information on materialized views
> - *Oracle Database SQL Tuning Guide* for more information on query rewrite, the optimizer and the SQL Access Advisor

Prerequisites

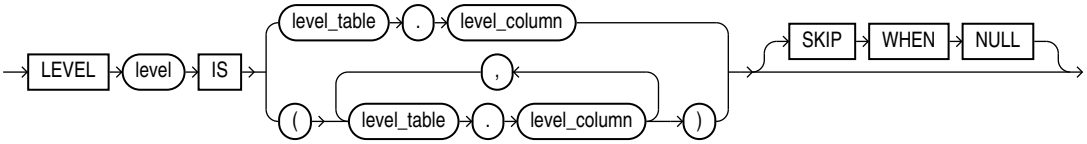
To create a dimension in your own schema, you must have the `CREATE DIMENSION` system privilege. To create a dimension in another user's schema, you must have the `CREATE ANY DIMENSION` system privilege. In either case, you must have the `READ` or `SELECT` object privilege on any objects referenced in the dimension.

Syntax

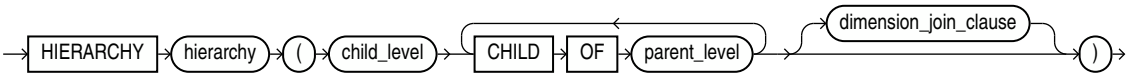
***create_dimension*::=**



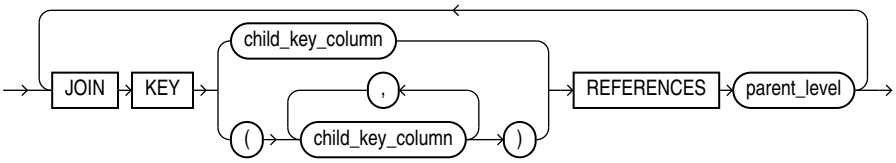
***level_clause*::=**



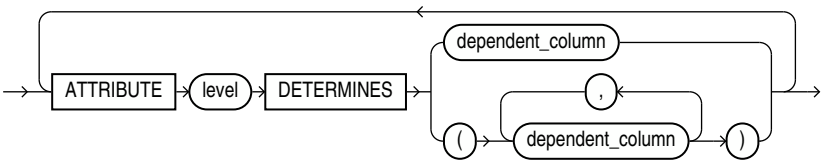
***hierarchy_clause*::=**



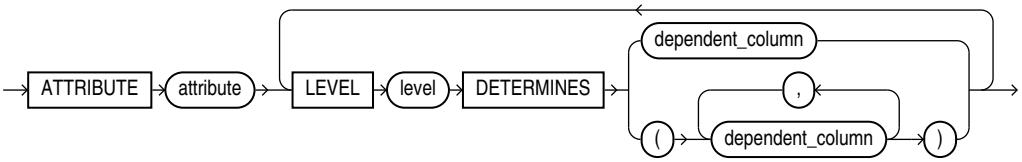
***dimension_join_clause*::=**



***attribute_clause*::=**



***extended_attribute_clause*::=**



Semantics

schema

Specify the schema in which the dimension will be created. If you do not specify *schema*, then Oracle Database creates the dimension in your own schema.

dimension

Specify the name of the dimension. The name must satisfy the requirements listed in "Database Object Naming Rules ".

level_clause

The *level_clause* defines a level in the dimension. A level defines dimension hierarchies and attributes.

level

Specify the name of the level.

level_table . level_column

Specify the columns in the level. You can specify up to 32 columns. The tables you specify in this clause must already exist.

SKIP WHEN NULL

Specify this clause to indicate that if the specified level is `NULL`, then the level is to be skipped. This clause lets you preserve the hierarchical chain of parent-child relationship by an alternative path that skips over the specified level. See *hierarchy_clause*.

Restrictions on Dimension Level Columns

Dimension level columns are subject to the following restrictions:

- All of the columns in a level must come from the same table.
- If columns in different levels come from different tables, then you must specify the *dimension_join_clause*.
- The set of columns you specify must be unique to this level.
- The columns you specify cannot be specified in any other dimension.
- Each `level_column` must be non-null unless the level is specified with `SKIP WHEN NULL`. The non-null columns need not have `NOT NULL` constraints. The column for which you specify `SKIP WHEN NULL` cannot have a `NOT NULL` constraint).

hierarchy_clause

The *hierarchy_clause* defines a linear hierarchy of levels in the dimension. Each hierarchy forms a chain of parent-child relationships among the levels in the dimension. Hierarchies in a dimension are independent of each other. They may, but need not, have columns in common.

Each level in the dimension should be specified at most once in this clause, and each level must already have been named in the *level_clause*.

hierarchy

Specify the name of the hierarchy. This name must be unique in the dimension.

child_level

Specify the name of a level that has an n:1 relationship with a parent level. The *level_columns* of *child_level* cannot be null, and each *child_level* value uniquely determines the value of the next named *parent_level*.

If the child *level_table* is different from the parent *level_table*, then you must specify a join relationship between them in the *dimension_join_clause*.

parent_level

Specify the name of a level.

dimension_join_clause

The *dimension_join_clause* lets you specify an inner equijoin relationship for a dimension whose columns are contained in multiple tables. This clause is required and permitted only when the columns specified in the hierarchy are not all in the same table.

child_key_column

Specify one or more columns that are join-compatible with columns in the parent level.

If you do not specify the schema and table of each *child_column*, then the schema and table are inferred from the `CHILD OF` relationship in the *hierarchy_clause*. If you do specify the schema and column of a *child_key_column*, then the schema and table must match the schema and table of columns in the child of *parent_level* in the *hierarchy_clause*.

parent_level

Specify the name of a level.

Restrictions on Join Dimensions

Join dimensions are subject to the following restrictions:

- You can specify only one *dimension_join_clause* for a given pair of levels in the same hierarchy.
- The *child_key_columns* must be non-null, and the parent key must be unique and non-null. You need not define constraints to enforce these conditions, but queries may return incorrect results if these conditions are not true.
- Each child key must join with a key in the *parent_level* table.
- Self-joins are not permitted. The *child_key_columns* cannot be in the same table as *parent_level*.

- All of the child key columns must come from the same table.
- The number of child key columns must match the number of columns in *parent_level*, and the columns must be joinable.
- You cannot specify multiple child key columns unless the parent level consists of multiple columns.

attribute_clause

The *attribute_clause* lets you specify the columns that are uniquely determined by a hierarchy level. The columns in *level* must all come from the same table as the *dependent_columns*. The *dependent_columns* need not have been specified in the *level_clause*.

For example, if the hierarchy levels are `city`, `state`, and `country`, then `city` might determine `mayor`, `state` might determine `governor`, and `country` might determine `president`.

extended_attribute_clause

This clause lets you specify an attribute name for one or more level-to-column relations. The type of attribute you create with this clause is not different from the type of attribute created using the *attribute_clause*. The only difference is that this clause lets you assign a name to the attribute that is different from the level name.

Examples

Creating a Dimension: Examples

This statement was used to create the `customers_dim` dimension in the sample schema `sh`:

```
CREATE DIMENSION customers_dim
   LEVEL customer   IS (customers.cust_id)
   LEVEL city       IS (customers.cust_city)
   LEVEL state      IS (customers.cust_state_province)
   LEVEL country    IS (countries.country_id)
   LEVEL subregion  IS (countries.country_subregion)
   LEVEL region     IS (countries.country_region)
   HIERARCHY geog_rollup (
      customer      CHILD OF
      city          CHILD OF
      state         CHILD OF
      country       CHILD OF
      subregion     CHILD OF
      region
   JOIN KEY (customers.country_id) REFERENCES country
   )
   ATTRIBUTE customer DETERMINES
   (cust_first_name, cust_last_name, cust_gender,
    cust_marital_status, cust_year_of_birth,
    cust_income_level, cust_credit_limit)
   ATTRIBUTE country DETERMINES (countries.country_name)
;
```

Creating a Dimension with Extended Attributes: Example

Alternatively, the *extended_attribute_clause* could have been used instead of the *attribute_clause*, as shown in the following example:

```
CREATE DIMENSION customers_dim
   LEVEL customer   IS (customers.cust_id)
   LEVEL city       IS (customers.cust_city)
```

```
   LEVEL state      IS (customers.cust_state_province)
   LEVEL country    IS (countries.country_id)
   LEVEL subregion  IS (countries.country_subregion)
   LEVEL region     IS (countries.country_region)
   HIERARCHY geog_rollup (
      customer      CHILD OF
      city          CHILD OF
      state         CHILD OF
      country       CHILD OF
      subregion     CHILD OF
      region
   JOIN KEY (customers.country_id) REFERENCES country
   )
   ATTRIBUTE customer_info LEVEL customer DETERMINES
   (cust_first_name, cust_last_name, cust_gender,
    cust_marital_status, cust_year_of_birth,
    cust_income_level, cust_credit_limit)
   ATTRIBUTE country DETERMINES (countries.country_name);
```

Creating a Dimension with NULL Column Values: Example

The following example shows how to create the dimension if one of the level columns is null and you want to preserve the hierarchical chain. The example uses the `cust_marital_status` column for simplicity because it is not a `NOT NULL` column. If it had such a constraint, then you would have to disable the constraint before using the `SKIP WHEN NULL` clause.

```
CREATE DIMENSION customers_dim
   LEVEL customer IS (customers.cust_id)
   LEVEL status IS (customers.cust_marital_status) SKIP WHEN NULL
   LEVEL city IS (customers.cust_city)
   LEVEL state IS (customers.cust_state_province)
   LEVEL country IS (countries.country_id)
   LEVEL subregion IS (countries.country_subregion) SKIP WHEN NULL
   LEVEL region IS (countries.country_region)
   HIERARCHY geog_rollup (
      customer CHILD OF
      city CHILD OF
      state CHILD OF
      country CHILD OF
      subregion CHILD OF
      region
   JOIN KEY (customers.country_id) REFERENCES country
   )
   ATTRIBUTE customer DETERMINES
   (cust_first_name, cust_last_name, cust_gender,
    cust_marital_status, cust_year_of_birth,
    cust_income_level, cust_credit_limit)
   ATTRIBUTE country DETERMINES (countries.country_name)
;
```

CREATE DIRECTORY

Purpose

Use the `CREATE DIRECTORY` statement to create a directory object. A directory object specifies an alias for a directory on the server file system where external binary file LOBs (`BFILE`s) and external table data are located. You can use directory names when referring to `BFILE`s in your PL/SQL code and OCI calls, rather than hard coding the operating system path name, for management flexibility.

All directories are created in a single namespace and are not owned by an individual schema. You can secure access to the BFILEs stored within the directory structure by granting object privileges on the directories to specific users.

> **See Also:**
>
> - "Large Object (LOB) Data Types " for more information on BFILE objects
> - GRANT for more information on granting object privileges
> - *external_table_clause*::= of CREATE TABLE

Prerequisites

You must have the CREATE ANY DIRECTORY system privilege to create directories.

When you create a directory, you are automatically granted the READ, WRITE, and EXECUTE object privileges on the directory, and you can grant these privileges to other users and roles. The DBA can also grant these privileges to other users and roles.

WRITE privileges on a directory are useful in connection with external tables. They let the grantee determine whether the external table agent can write a log file or a bad file to the directory.

For file storage, you must also create a corresponding operating system directory, an Oracle Automatic Storage Management (Oracle ASM) disk group, or a directory within an Oracle ASM disk group. Your system or database administrator must ensure that the operating system directory has the correct read and write permissions for Oracle Database processes.

Privileges granted for the directory are created independently of the permissions defined for the operating system directory, and the two may or may not correspond exactly. For example, an error occurs if sample user hr is granted READ privilege on the directory object but the corresponding operating system directory does not have READ permission defined for Oracle Database processes.

Restrictions

Symbolic links are not allowed in the directory object paths or filenames when opening BFILE objects. The entire directory path and filename is checked and the following error is returned if any symbolic link is found:

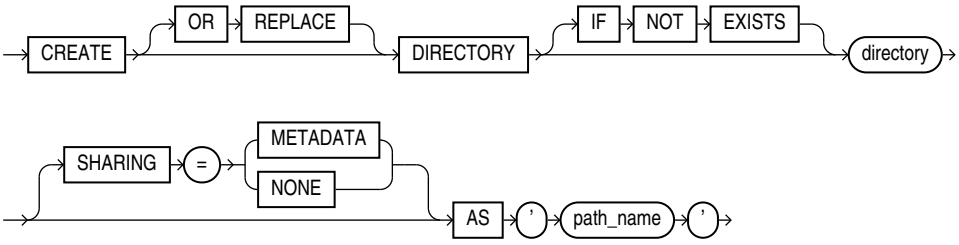
```
ORA-22288: file or LOB operation FILEOPEN failed soft link in path
```

Workaround

If the database directory object or filename you are trying to open contains symbolic links, change it to provide the real path and filename.

Syntax

***create_directory*::=**



Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the directory database object if it already exists. You can use this clause to change the definition of an existing directory without dropping, re-creating, and regranting database object privileges previously granted on the directory.

Users who had previously been granted privileges on a redefined directory can still access the directory without being regranted the privileges.

> **See Also:**
>
> DROP DIRECTORY for information on removing a directory from the database

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the directory does not exist, a new directory is created at the end of the statement.
- If the directory exists, this is the directory you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

SHARING

This clause applies only when creating a directory in an application root. This type of directory is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the directory is shared, specify one of the following sharing attributes:

- `METADATA` - A metadata link shares the directory's metadata, but its data is unique to each container. This type of directory is referred to as a **metadata-linked application common object**.

- `NONE` - The directory is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the directory. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

You cannot change the sharing attribute of a directory after it is created.

> **See Also:**
>
> - *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
> - *Oracle Database Administrator's Guide* for complete information on creating application common objects

directory

Specify the name of the directory object to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

Oracle Database does not verify that the directory you specify actually exists. Therefore, take care that you specify a valid directory in your operating system. In addition, if your operating system uses case-sensitive path names, then be sure you specify the directory in the correct format. You need not include a trailing slash at the end of the path name.

Do not refer to a parent directory in the directory name. For example, the following syntax is valid:

```
CREATE DIRECTORY mydir AS '/scratch/data/file_data';
```

However, the following syntax is not valid:

```
CREATE DIRECTORY mydir AS '/scratch/../file_data';
```

path_name

Specify the full path name of the operating system directory of the server where the files are located. The single quotation marks are required, with the result that the path name is case sensitive.

Examples

Creating a Directory: Examples

The following statement creates a directory database object that points to a directory on the server:

```
CREATE DIRECTORY admin AS '/disk1/oracle/admin';
```

The following statement redefines directory database object `bfile_dir` to enable access to `BFILE`s stored in the operating system directory /`usr/bin/bfile_dir`:

```
CREATE OR REPLACE DIRECTORY bfile_dir AS '/usr/bin/bfile_dir';
```

CREATE DISKGROUP

> **Note:**
>
> This SQL statement is valid only if you are using Oracle ASM and you have started an Oracle ASM instance. You must issue this statement from within the Oracle ASM instance, not from a normal database instance. For information on starting an Oracle ASM instance, refer to *Oracle Automatic Storage Management Administrator's Guide*.

Purpose

Use the `CREATE DISKGROUP` clause to name a group of disks and specify that Oracle Database should manage the group for you. Oracle Database manages a disk group as a logical unit and evenly spreads each file across the disks to balance I/O. Oracle Database also automatically distributes database files across all available disks in disk groups and rebalances storage automatically whenever the storage configuration changes.

This statement creates a disk group, assigns one or more disks to the disk group, and mounts the disk group for the first time. Note that `CREATE DISKGROUP` only mounts a disk group on the local node. If you want Oracle ASM to mount the disk group automatically in subsequent instances, then you must add the disk group name to the value of the `ASM_DISKGROUPS` initialization parameter in the initialization parameter file. If you use an `SPFILE`, then the disk group is added to the initialization parameter automatically.

> **See Also:**
>
> - ALTER DISKGROUP for information on modifying disk groups
> - *Oracle Automatic Storage Management Administrator's Guide* for information on Oracle ASM and using disk groups to simplify database administration
> - `ASM_DISKGROUPS` for more information about adding disk group names to the initialization parameter file
> - `V$ASM_OPERATION` for information on monitoring Oracle ASM operations
> - DROP DISKGROUP for information on dropping a disk group

Prerequisites

You must have the `SYSASM` system privilege to issue this statement.

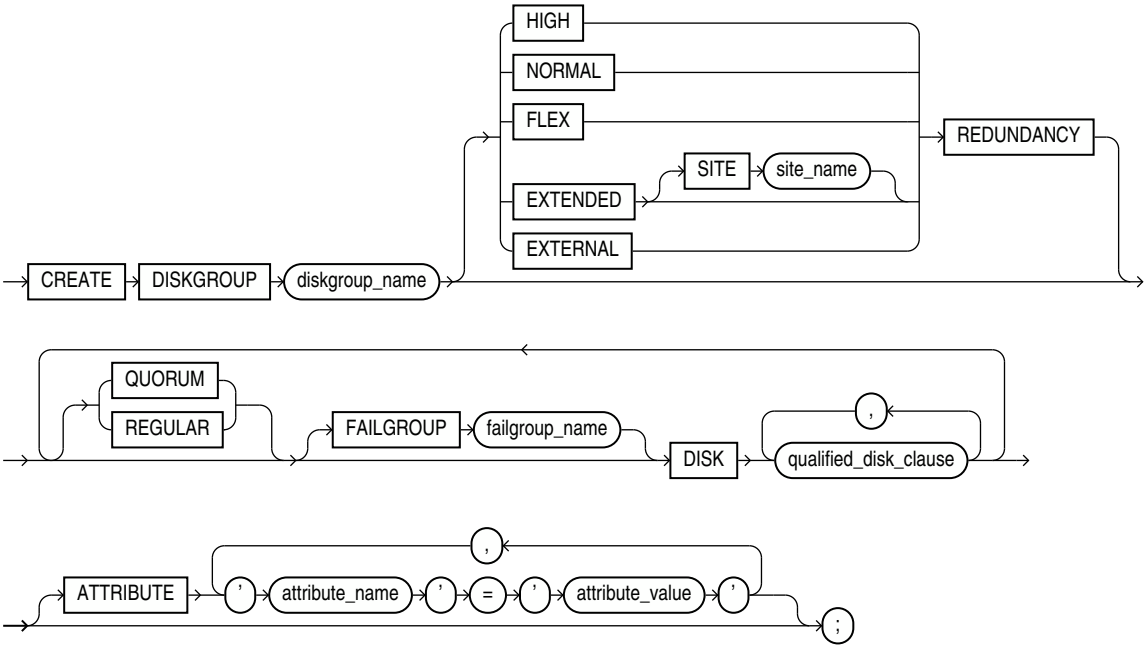
Before issuing this statement, you must format the disks using an operating system format utility. Also ensure that the Oracle Database user has read/write permission and the disks can be discovered using the `ASM_DISKSTRING`.

When you store your database files in Oracle ASM disk groups, rather than in a file system, before the database instance can access your files in the disk groups, you must configure and start up an Oracle ASM instance to manage the disk groups.

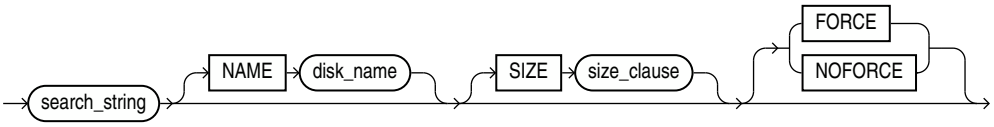
Each database instance communicates with a single Oracle ASM instance on the same node as the database. Multiple database instances on the same node can communicate with a single Oracle ASM instance.

Syntax

***create_diskgroup*::=**



***qualified_disk_clause*::=**



(*size_clause*::=)

diskgroup_name

Specify the name of the disk group. The name must satisfy the requirements listed in "Database Object Naming Rules ". However, disk groups are not schema objects.

> **Note:**
>
> Oracle does not recommend using quoted identifiers for disk group names. These quoted identifiers are accepted when issuing the `CREATE DISKGROUP` statement in SQL*Plus, but they may not be valid when using other tools that manage disk groups.

REDUNDANCY Clause

The REDUNDANCY clause lets you specify the redundancy level of the disk group.

- NORMAL REDUNDANCY requires the existence of at least two failure groups (see the FAILGROUP clause that follows). Oracle ASM provides redundancy for all files in the disk group according to the attributes specified in the disk group templates. NORMAL REDUNDANCY disk groups can tolerate the loss of one group. Refer to ALTER DISKGROUP ... *diskgroup_template_clauses* for more information on disk group templates.

  NORMAL REDUNDANCY is the default if you omit the REDUNDANCY clause. Therefore, if you omit this clause, you must create at least two failure groups, or the create operation will fail.
- HIGH REDUNDANCY requires the existence of at least three failure groups. Oracle ASM fixes mirroring at 3-way mirroring, with each extent getting two mirrored copies. HIGH REDUNDANCY disk groups can tolerate the loss of two failure groups.
- FLEX REDUNDANCY is a type of disk group that allows a database to specify its own redundancy after the disk group is created. A file's redundancy can also be changed after its creation. This type of disk group supports Oracle ASM file groups and quota groups. A flex disk group requires the existence of at least three failure groups. If a flex disk group has fewer than five failure groups, then it can tolerate the loss of one; otherwise, it can tolerate the loss of two failure groups. To create a flex disk group, the COMPATIBLE.ASM and COMPATIBLE.RDBMS disk group attributes must be set to 12.2 or greater.
- EXTENDED REDUNDANCY is a disk group that has all the features of a flex disk group in addition to being highly available in an extended cluster environment. The cluster contains nodes that span multiple physically separated sites. For more see About Oracle ASM Extended Disk Groups

  You can use the SITE keyword to specify the redundancy of files and file groups in an extended disk group for each site, rather than for each disk group.
- EXTERNAL REDUNDANCY indicates that Oracle ASM does not provide any redundancy for the disk group. The disks within the disk group must provide redundancy (for example, using a storage array), or you must be willing to tolerate loss of the disk group if a disk fails (for example, in a test environment). You cannot specify the FAILGROUP clause if you specify EXTERNAL REDUNDANCY.

You cannot change the redundancy level after the disk group has been created, with the following exception: You can convert a normal or high redundancy disk group to a flex disk group. For more information, see the *convert_redundancy_clause* of ALTER DISKGROUP.

QUORUM | REGULAR

Use these keywords to qualify either failure group or disk specifications.

- REGULAR disks, or disks in non-quorum failure groups, can contain any files.
- QUORUM disks, or disks in quorum failure groups, cannot contain any database files, the Oracle Cluster Registry (OCR), or dynamic volumes. However, QUORUM disks can contain the voting file for Cluster Synchronization Services (CSS). Oracle ASM uses quorum disks or disks in quorum failure groups for voting files whenever possible.

  A quorum failure group is not considered when determining redundancy requirements with respect to storing user data.

If you specify neither keyword, then REGULAR is the default.

Specify either `QUORUM` or `REGULAR` before the keyword `FAILGROUP` if you are explicitly specifying the failure group. If you are creating a disk group with implicitly created failure groups, then specify these keywords before the keyword `DISK`.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for more information about quorum and regular disks and failure groups

FAILGROUP Clause

Use this clause to specify a name for one or more failure groups. If you omit this clause, and you have specified `NORMAL` or `HIGH REDUNDANCY`, then Oracle Database automatically adds each disk in the disk group to its own failure group. The implicit name of the failure group is the same as the operating system independent disk name (see "NAME Clause").

You cannot specify this clause if you are creating an `EXTERNAL REDUNDANCY` disk group.

qualified_disk_clause

Specify `DISK` *`qualified_disk_clause`* to add a disk to a disk group.

search_string

For each disk you are adding to the disk group, specify the operating system dependent search string that Oracle ASM will use to find the disk. The *`search_string`* must point to a subset of the disks returned by discovery using the strings in the `ASM_DISKSTRING` initialization parameter. If *`search_string`* does not point to any disks the Oracle Database user has read/write access to, then Oracle ASM returns an error. If it points to one or more disks that have already been assigned to a different disk group, then Oracle Database returns an error unless you also specify `FORCE`.

For each valid candidate disk, Oracle ASM formats the disk header to indicate that it is a member of the new disk group.

> **See Also:**
>
> The `ASM_DISKSTRING` initialization parameter for more information on specifying the search string

NAME Clause

The `NAME` clause is valid only if the *`search_string`* points to a single disk. This clause lets you specify an operating system independent name for the disk. The name can be up to 30 characters long and can contain only alphanumeric characters. The first character must be alphabetic. If you omit this clause and you assigned a label to a disk through ASMLIB, then that label is used as the disk name. If you omit this clause and you did not assign a label through ASMLIB, then Oracle ASM creates a default name of the form *`diskgroupname_####`*, where *`####`* is the disk number. You use this name to refer to the disk in subsequent Oracle ASM operations.

SIZE Clause

Use this clause to specify in bytes the size of the disk. If you specify a size greater than the capacity of the disk, then Oracle ASM returns an error. If you specify a size less than the capacity of the disk, then you limit the disk space Oracle ASM will use. The size value must be identical for all disks in a disk group. If you omit this clause, then Oracle ASM attempts programmatically to determine the size of the disk.

FORCE

Specify `FORCE` if you want Oracle ASM to add the disk to the disk group even if the disk is already a member of a different disk group.

> **Note:**
>
> Using `FORCE` in this way may destroy existing disk groups.

For this clause to be valid, the disk must already be a member of a disk group and the disk cannot be part of a mounted disk group.

NOFORCE

Specify `NOFORCE` if you want Oracle ASM to return an error if the disk is already a member of a different disk group. `NOFORCE` is the default.

ATTRIBUTE Clause

Use this clause to set attribute values for the disk group. You can view the current attribute values by querying the `V$ASM_ATTRIBUTE` view. Table 13-2 lists the attributes you can set with this clause. All attribute values are strings.

Table 13-2 Disk Group Attributes

Attribute	Valid Values	Description
`ACCESS_CONTROL.ENABLED`	`true` or `false`	Specifies whether Oracle ASM File Access Control is enabled for a disk group. If set to `true`, accessing Oracle ASM files is subject to access control. If `false`, any user can access every file in the disk group. All other operations behave independently of this attribute. The default value is `false`. If both the `compatible.rdbms` and `compatible.asm` attributes are set to at least 11.2, you can set this attribute in an `ALTER DISKGROUP ... SET ATTRIBUTE` statement. You cannot set this attribute when creating a disk group. When you set up file access control on an existing disk group, the files previously created remain accessible by everyone, unless you run the `ALTER DISKGROUP SET PERMISSION` statement to restrict the permissions. **Note**: This attribute is used in conjunction with `ACCESS_CONTROL.UMASK` to manage Oracle ASM File Access Control. After setting the `ACCESS_CONTROL.ENABLED` disk attribute, you must set permissions with the `ACCESS_CONTROL.UMASK` attribute.

Table 13-2 (Cont.) Disk Group Attributes

Attribute	Valid Values	Description
ACCESS_CONTROL.UMASK	A three-digit number where each digit is 0, 2, or 6.	Determines which permissions are masked out on the creation of an Oracle ASM file for the user that owns the file (first digit), users in the same user group (second digit), and others not in the user group (third digit). This attribute applies to all files on a disk group. Setting to 0 masks out nothing. Setting to 2 masks out write permission. Setting to 6 masks out both read and write permissions. The default value is 066. If both the compatible.rdbms and compatible.asm attributes are set to at least 11.2, you can set this attribute in an ALTER DISKGROUP ... SET ATTRIBUTE statement. You cannot set this attribute when creating a disk group. When you set up file access control on an existing disk group, the files previously created remain accessible by everyone, unless you run the ALTER DISKGROUP SET PERMISSION statement to restrict the permissions. **Note**: This attribute is used in conjunction with ACCESS_CONTROL.ENABLED to manage Oracle ASM File Access Control. Before setting ACCESS_CONTROL.UMASK, you must set ACCESS_CONTROL.ENABLED to true.
AU_SIZE	Size in bytes. Valid values are powers of 2 from 1M to 64M. Examples '4M', '4194304'.	Specifies the allocation unit size. This attribute can be set only during disk group creation; it cannot be modified with an ALTER DISKGROUP statement.
COMPATIBLE.ADVM	Valid Oracle Database version number[1]	Determines whether the disk group can contain Oracle ADVM volumes. The value must be set to 11.2 or higher. Before setting this attribute, the COMPATIBLE.ASM value must be 11.2 or higher. Also, the Oracle ADVM volume drivers must be loaded. By default, the value of the COMPATIBLE.ADVM attribute is empty until set.
COMPATIBLE.ASM	Valid Oracle Database version number[1]	Determines the minimum software version for an Oracle ASM instance that can use the disk group. This setting also affects the format of the data structures for the Oracle ASM metadata on the disk. For Oracle ASM in Oracle Database 11*g*, 10.1 is the default setting for the COMPATIBLE.ASM attribute when using the SQL CREATE DISKGROUP statement, the ASMCMD mkdg command, and Oracle Enterprise Manager **Create Disk Group** page. When creating a disk group with ASMCA, the default setting is 11.2.

Table 13-2 (Cont.) Disk Group Attributes

Attribute	Valid Values	Description
COMPATIBLE.RDBMS	Valid Oracle Database version number[1]	Determines the minimum COMPATIBLE database initialization parameter setting for any database instance that is allowed to use the disk group. Before advancing the COMPATIBLE.RDBMS attribute, ensure that the values for the COMPATIBLE initialization parameter for all of the databases that access the disk group are set to at least the value of the new setting for COMPATIBLE.RDBMS. For example, if the COMPATIBLE initialization parameters of the databases are set to either 11.1 or 11.2, then COMPATIBLE.RDBMS can be set to any value between 10.1 and 11.1 inclusively. For Oracle ASM in Oracle Database 11*g*, 10.1 is the default setting for the COMPATIBLE.RDBMS attribute when using the SQL CREATE DISKGROUP statement, the ASMCMD mkdg command, ASMCA **Create Disk Group** page, and Oracle Enterprise Manager **Create Disk Group** page.
CONTENT.CHECK	true or false	Enables (true) or disables (false) content checking when performing data copy operations for rebalancing a disk group. You cannot set this attribute when creating a disk group. The default value is dependent on the COMPATIBLE.ASM attribute and follows this rule: • If COMPATIBLE.ASM > = 19.0.0.0.0, then CONTENT.CHECK defaults to true. • If COMPATIBLE.ASM < 19.0.0.0.0, then CONTENT.CHECK defaults to false. **Note**: This rule is ONLY true for the creation of new diskgroups. If the COMPATIBLE.ASM attribute of an existing diskgroup is updated to 19.0.0.0.0 or above, the CONTENT.CHECK attribute remains at its current value.
DISK_REPAIR_TIME	0 to 136 years	When disks are taken offline, Oracle ASM drops them after a default period of time. If both the compatible.rdbms and compatible.asm attributes are set to at least 11.1, you can set the disk_repair_time attribute in an ALTER DISKGROUP ... SET ATTRIBUTE statement to change that default period of time so that the disk can be repaired and brought back online. You cannot set this attribute when creating a disk group. The time can be specified in units of minute (M) or hour (H). The specified time elapses only when the disk group is mounted. If you omit the unit, then the default is H. If you omit this attribute, and both compatible.rdbms and compatible.asm are set to at least 11.1, then the default is 12 H. Otherwise the disk is dropped immediately. You can override this attribute with an ALTER DISKGROUP ... OFFLINE DISK statement and the DROP AFTER clause. **Note**: If a disk is taken offline using the current value of disk_repair_time, and the value of this attribute is subsequently changed, then the changed value is used by Oracle ASM in the disk offline logic. **See Also**: The ALTER DISKGROUP ... *disk_offline_clause* and *Oracle Automatic Storage Management Administrator's Guide* for more information

Table 13-2 (Cont.) Disk Group Attributes

Attribute	Valid Values	Description
FAILGROUP_REPAIR_TIME	<number>m (number of minutes) or <number>h (number of hours)	Specifies a default repair time for the failure groups in the disk group. The failure group repair time is used if Oracle ASM determines that an entire failure group has failed. The default value is 24 hours (24h). If there is a repair time specified for a disk, such as with the DROP AFTER clause of the ALTER DISKGROUP OFFLINE DISK statement, then that disk repair time overrides the failure group repair time. This attribute can only be set when altering a disk group and is only applicable to normal and high redundancy disk groups.
LOGICAL_SECTOR_SIZE	512, 4096, or 4K	Sets the logical sector size of a disk group. This value specifies the smallest possible I/O that the disk group can accept. The default value is estimated from the disks that join the disk group. To set this disk group attribute during the creation of a disk group or to alter it after a disk group has been created, the COMPATIBLE.ASM disk group attribute must be set to 12.2 or higher.
PHYS_META_REPLICATED	true or false	Tracks the replication status of a disk group. When the Oracle ASM compatibility of a disk group is advanced to 12.0 or higher, the physical metadata of each disk, including its disk header, free space table blocks and allocation table blocks, is replicated. The replication is performed online asynchronously. PHYS_META_REPLICATED is set to true by Oracle ASM if the physical metadata of every disk in the disk group has been replicated. This disk group attribute is only defined in a disk group with the Oracle ASM disk group compatibility (COMPATIBLE.ASM) set to 12.0 and higher. This attribute is read-only and is intended for information only. You cannot set or change its value.
PREFERRED_READ.ENABLED	true or false	In an Oracle extended cluster, which contains nodes that span multiple physically separated sites, the PREFERRED_READ.ENABLED disk group attribute controls whether preferred read functionality is enabled for a disk group. If preferred read functionality is enabled, then this functionality enables an instance to determine and read from disks at the same site as itself, which can improve performance. For extended clusters, the default value is true. For clusters that are not extended (only one physical site), preferred read is disabled (false). Preferred read status applies to extended, normal, high, and flex redundancy disk groups. This disk group attribute is only defined in a disk group with the Oracle ASM disk group compatibility (COMPATIBLE.ASM) set to 12.2 and higher.
SECTOR_SIZE	512, 4096, or 4K	Sets the physical sector size of a disk group. All disks in the disk group must have this physical sector size. The default value is obtained from the disks that join the disk group. To set this disk group attribute during the creation of a disk group, the COMPATIBLE.ASM and COMPATIBLE.RDBMS disk group attributes must be set to 11.2 or higher. To alter this disk group attribute after a disk group has been created, the COMPATIBLE.ASM disk group attribute must be set to 12.2 or higher.
THIN_PROVISIONED	true or false	Enables (true) or disables (false) the functionality to discard unused storage space after a disk group rebalance is completed. The default value is false.

Table 13-2 (Cont.) Disk Group Attributes

Attribute	Valid Values	Description
CONTENT_HARDCHECK	true or false	CONTENT_HARDCHECK enables or disables Hardware Assisted Resilient Data (HARD) checking when performing data copy operations for rebalancing a disk group. This attribute can only be set when altering a disk group.

[1] Specify at least the first two digits of a valid Oracle Database release number. Refer to *Oracle Database Administrator's Guide* for information on specifying valid version numbers. For example, you can specify compatibility as '11.2' or '12.1'.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for more information on managing these attribute settings

Examples

The following example assumes that the ASM_DISKSTRING parameter is a superset of /devices/disks/c*, /devices/disks/c* points to at least one device to be used as an Oracle ASM disk, and the Oracle Database user has read/write permission to the disks.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide* for information on Oracle ASM and using disk groups to simplify database administration

Creating a Diskgroup: Example

The following statement creates an Oracle ASM disk group dgroup_01 where no redundancy for the disk group is provided by Oracle ASM and includes all disks that match the *search_string*:

```
CREATE DISKGROUP dgroup_01
  EXTERNAL REDUNDANCY
  DISK '/devices/disks/c*';
```

CREATE DOMAIN

Purpose

Use CREATE DOMAIN to create a data use case domain. A use case domain is high-level dictionary object that belongs to a schema and encapsulates a set of optional properties and constraints.

You can define table columns to be associated with a domain, thereby explicitly applying the domain's optional properties and constraints to the columns.

At minimum, a domain must specify a built-in Oracle data type. The qualified domain name should not collide with the qualified user-defined data types, or with Oracle built-in data types.

The domain data type must be a single Oracle data type. For Oracle character data type you must specify a maximum length, one of `VARCHAR2(L [CHAR|BYTE])`, `NVARCHAR2(L)`, `CHAR(L [CHAR|BYTE])`, or `NCHAR(L)`.

Domain-Specific Expressions and Conditions

A domain expression can be one of *simple*, *datetime*, *interval*, *CASE*, *compound*, or *list domain expression* :

- A *simple domain expression* is one of `string`, `number`, `sequence.CURRVAL`, `sequence.NEXTVAL`, `NULL`, or `schema.domain`. It is similar to simple expressions, except that it references domain names instead of column names. It references domain names as qualified names, names of Oracle built-in domains or uses a `PUBLIC` synonym to a domain.
- A *datetime domain expression* is a datetime expression that references domain expressions only.
- An *interval domain expression* is defined just as a regular interval expression, except that it references domain expressions. For example, `(SYSTIMESTAMP - day_of_week) DAY(9) TO SECOND` is an interval domain expression.
- A *compound domain expression* is any of: `(expr)`, `expr op expr` with op `+`, `-`, `*`, `/`, `||`, or `expr COLLATE collation_name`, where `expr` is a domain expression.

  Examples of valid compound domain expressions

  ```
  'email: ' || EmailAddress

  day_of_week + INTERVAL '1' DAY

  TO_CHAR(LastFour(SSN))
  ```

- A *case domain expression* is a like a regular case expression except that it references domain expressions only.

  Examples of valid case domain expressions

  ```
  CASE
    WHEN UPPER(DOMAIN_DISPLAY(day_of_week)) IN ('SAT','SUN')
    THEN 'weekend'
    ELSE 'week day'
  END
  ```

- Similar to the definition of use case domain expressions, a domain condition is like a regular SQL condition, except that it references only domain expressions. You can use the keyword `VALUE` in domain expressions instead of the domain name. For example:

  ```
  CREATE DOMAIN day_of_week AS CHAR(3 CHAR)
     CONSTRAINT day_of_week_c
       CHECK (UPPER(VALUE) IN ('MON', 'TUE', 'WED', 'THU', 'FRI', 'SAT', 'SUN'))
     DEFERRABLE INITIALLY DEFERRED
     DISPLAY SUBSTR(VALUE, 1, 2);
  ```

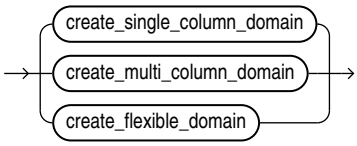
Prerequisites

To create a domain in your own schema, you must have the `CREATE DOMAIN` system privilege.

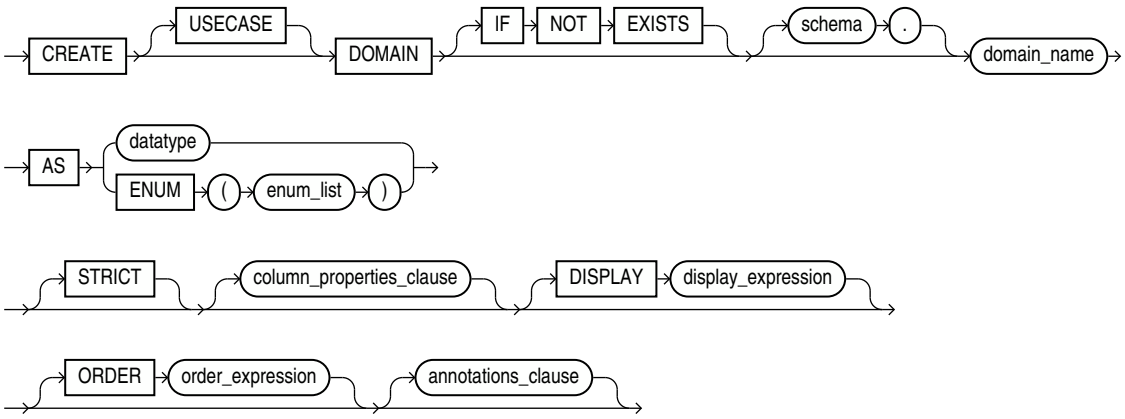
To create a domain in another user's schema, you must have the `CREATE ANY DOMAIN` system privilege.

Syntax

***create_domain*::=**

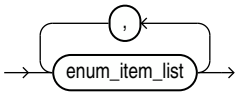


***create_single_column_domain*::=**



(*datatype*::=)

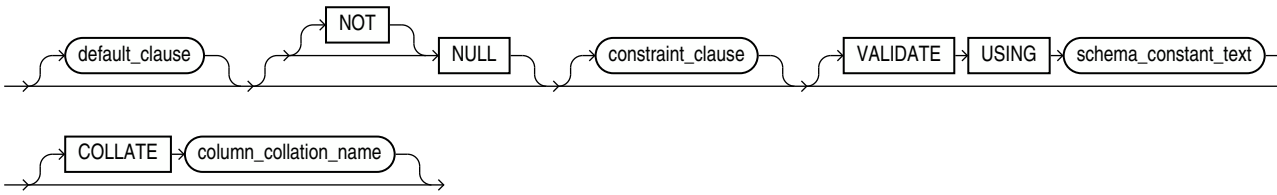
***enum_list*::=**



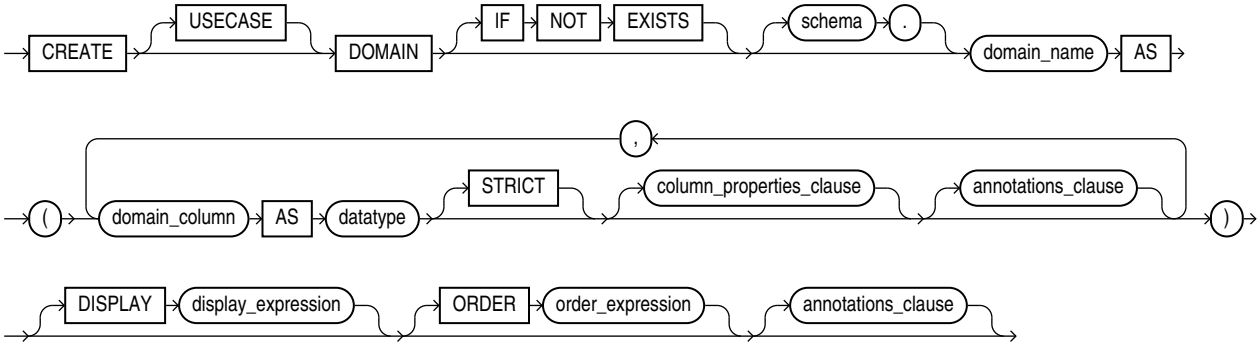
***enum_item_list*::=**

***enum_alias_list*::=**

***column_properties_clause*::=**

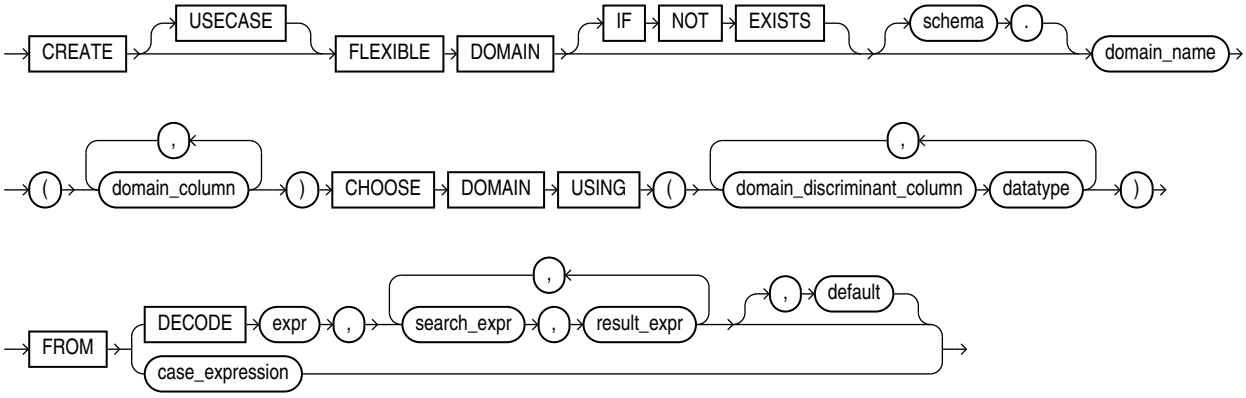


***create_multi_column_domain*::=**



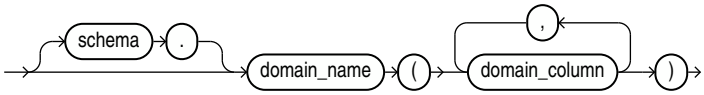
(*datatype*::=)

***create_flexible_domain*::=**

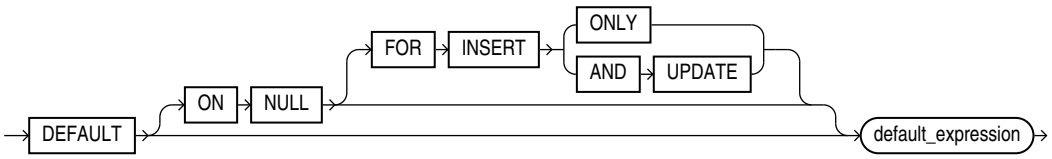


datatype::=,CASE Expressions

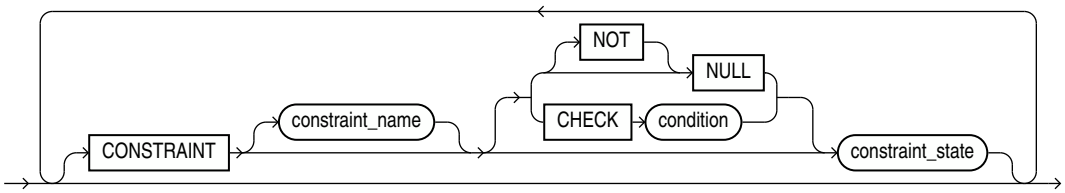
***result_expr*::=**



***default_clause*::=**



***constraint_clause*::=**



***annotations_clause*::=**

For the full syntax and semantics of the *annotations_clause* see *annotations_clause*.

Semantics

USECASE

This keyword is optional and is provided for semantic clarity. It indicates that the domain is to describe a data use case.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the domain does not exist, a new domain is created at the end of the statement.
- If the domain exists, a new one is not created because the older one is detected.

Using `IF EXISTS` with `CREATE` results in the following error: `Incorrect IF NOT EXISTS clause for CREATE statement.`

domain_name

domain_name follows the same restrictions as any type name and must not collide with the name of any object in the domain schema, any Oracle supplied data type, and any Oracle supplied domain.

These restrictions apply at a PDB-level in a CDB environment.

Note that domains are schema-level catalog objects, and therefore subject to schema-level object restrictions.

datatype

datatype must be an Oracle built-in data type like:

- `CHAR(L [CHAR|BYTE])`, `NCHAR(L)`, `VARCHAR(L [CHAR|BYTE])`, `VARCHAR2(L [CHAR|BYTE])`, `NVARCHAR2(L)`
- `NUMBER[p, [s]]`, `FLOAT`, `BINARY_FLOAT`, `BINARY_DOUBLE`
- `RAW`, `LONG RAW` (extended included)
- `DATE`, `TIMESTAMP (WITH (LOCAL) TIME ZONE)`, `INTERVAL`
- `BFILE`, `BLOB`, `CLOB`, `NCLOB`
- `JSON` native data type
- `BOOLEAN`

ENUM

Specify `ENUM` to create an enumeration domain. An enumeration domain consists of a set of names and, optionally, a value corresponding to name. The name has to be a valid SQL identifier and every specified value must be a literal or a constant expression. The values can be of any data type that are supported for a data use case domain, but all of them must agree on that data type.

An enumeration domain has a default check-constraint, a display-expression, and an order-expression. This check-constraint cannot be dropped using `ALTER DOMAIN`.

The names inside a enumeration domain can be used wherever a literal is allowed in a scalar SQL expression, and the domain itself can be used in the `FROM` clause of a `SELECT` statement as if it were a table.

The collection of names (*`name`*) in an enumeration domain must be unique. There is no limit on number of names (or their aliases) in a enumeration, besides whatever limits already exist in Oracle SQL.

The data type of all the values (*`value`*) must match. If you do not specify a value, the default value of the first name is 1, and the value of every other unspecified name is one more than the previous value.

The expression defining the default must be one of the enumeration names without any expression besides that.

STRICT

When you specify `STRICT`, table columns linked with the domain must have the same data type limits as the corresponding domain columns. For example, if the data type of a domain column is `NUMBER(10)`, you can only associate it with columns declared as `NUMBER(10)`. Applying the domain to columns of `NUMBER(9)` or `NUMBER(11)` will raise a type error.

If you omit `STRICT`, you can link the domain to columns with type limits greater than or equal to the domain's limit. For example, you can apply a non-strict domain with the data type `NUMBER(10)` to columns with the data type `NUMBER(20)`.

If you associate a column with a domain without specifying the column's data type, then it uses `STRICT` semantics.

default_clause

If you specify the `ON NULL` clause, an implicit `NOT NULL` constraint is added.

default_expression

default_expression must be a domain expression and must conform to all the restrictions on default column expressions of the given data type, when applied to domain expressions:

- *default_expression* cannot contain a SQL function that returns a domain reference, or a nested function invocation, and it cannot be a subquery expression.
- The datatype of *default_expression* must match the domain's specified data type.
- As a domain expression, *default_expression* cannot refer to any table or column. It cannot refer to any other domain name.
- *default_expression* may refer to NEXTVAL and CURRVAL for a sequence. It cannot reference a PL/SQL function.

constraint_clause

Note that domain constraints can have optional names. They are NOT NULL, NULL or CHECK constraints. Multiple such constraint clauses can be specified both at the column and domain level.

The CHECK conditions as well as expressions in ALTER DOMAIN can only refer to domain columns. If the domain has a single column, the column name is either the domain name or the keyword VALUE, but the same expression cannot contain both domain name and VALUE as column name.

constraint_name is optional. When specified, it must not collide with a name of any other constraint in the domain's schema (in the given PDB if in a CDB environment). When not specified, a system-generated name will be used. Domain constraints follow the same rules as table and column-level constraints: a named table or column-level constraint cannot coincide with the name of any other constraint in the same schema. Domain constraints can share names with tables, even in the same schema. They can share names with columns, and it is possible for a constraint to have the same name as the table or column it is defined on.

The CHECK condition must be a domain logical condition and must conform to all the restrictions on CHECK constraints translated to domain expressions:

- It can only refer to *domain_name*, like a CHECK constraint on a column can only refer to a column. It cannot refer to any columns in any table or view, even within the domain schema.
- Subquery or scalar query expressions cannot be used.
- Condition cannot refer to non-deterministic functions (like CURRENT_DATE), or user-defined PL/SQL functions.
- CHECK IS JSON (STRICT) constraints are allowed.

  CHECK IS JSON(VALIDATE USING schema_constant_text) is allowed. You can specify the JSON schema and use it to validate that the JSON column respects the schema definition that is specified. *schema_constant_text* can be a constant literal with the JSON schema text, or a bind variable for the JSON schema text. The bind must be a runtime constant. It cannot be a domain.

  If you use the IS JSON constraint without specifying VALIDATE USING schema_constraint, any JSON value will be accepted. But when you specify a JSON Schema with VALIDATE USING schema_constraint , and the entered input data into the table column does not follow the schema, a JSON schema validation error is raised.

You can use shorthand syntax to specify the JSON schema with `VALIDATE USING schema_constant_text`.

Just as for table and column-level constraints, you can specify only one JSON constraint for a given table column

- The `CHECK` constraint condition is applied to one value at a time, and it is satisfied if the `CHECK` condition, with *`domain_name`* substituted by the value, evaluates to `TRUE` or `UNKNOWN`.

Domain constraints may be enforced in any order.

NULL constraint means that values of the domain are allowed to be NULL, and this is the default.

When *`constraint_state`* is not specified, the constraint is `NOT DEFERABLE INITIALLY IMMEDIATE`.

COLLATE

When collation is specified, it conforms to all the restrictions of column-level or schema-level collation. The data type must be a character data type if collation is specified.

You must ensure that all columns of a domain with a collation specified have the same collation as that of their domain.

If no collation is specified, and the data type is collatable, then the column's collation is used if specified. Otherwise the underlying default data type collation in the domain's schema is used.

An error is raised in the following cases:

- If you create a table with a column in a domain with a collation different than the column's collation.
- If you alter a column to have a collation different than the collation of the column's domain.
- If you alter a domain to add or modify the domain's collation to a value different than the collation of any column marked of the given domain.

You can specify the `COLLATE` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

display_expression

Use *`display_expression`* to format the data according to domain specifications. It can be of any data type allowed as a domain data type. *`display_expression`* must be a domain expression that does not contain table or view columns, subqueries, non-deterministic functions, or PL/SQL functions. It can refer to *`domain_name`*. If you do not specify collation for the expression, then *`display_expression`* uses the domain's collation, if it is specified.

order_expression

Use *`order_expression`* to order and compare values for domain specifications.

`order_expression` must conform to the same restrictions as display_expressions, and additionally must be of a byte or char-comparable data type. It returns *`order_expression`* with *`domain_name`* replaced by expression, if *`order_expression`* is specified for the expression's domain, or expression otherwise

annotations_clause

For examples of the *`annotations_clause`* see the examples at the end.

For the full semantics of the annotations clause see *annotations_clause*.

FROM Clause of Create Flexible Domain

expr and *comparison_expr* reference domain discriminant columns in the list *domain_discriminant_column*.

The `FROM` clause for flexible domain is either a `DECODE` or a `CASE` expression that refers only to discriminant column names (in the list following `CHOOSE DOMAIN USING`) in the search expressions and has only domain name followed by a list of columns in the result expressions. The columns in the result expression must be only columns in the domain column list (following `CREATE FLEXIBLE DOMAIN`).

Examples

Create Domain year_of_birth

The following example creates the single column domain `year_of_birth`. The check constraint ensures that the column's value is an integer with a value greater than or equal to 1900. The display clause formats the output of calls to `domain_display` to either `19-YY` or `20-YY`, where `YY` is the last two digits of the value. The order clause sorts calls to `domain_order` in order by the column value minus 1900.

```
CREATE DOMAIN year_of_birth AS NUMBER(4)
      CONSTRAINT CHECK ( (trunc(year_of_birth) = year_of_birth) and (year_of_birth >=
1900) )
      DISPLAY (CASE WHEN year_of_birth < 2000 THEN '19-' ELSE '20-' END) ||
MOD(year_of_birth, 100)
      ORDER year_of_birth-1900 ;
```

Create Domain day_of_week

The following statement creates the single column domain `day_of_week`. The check constraint ensures that its values are one of `MON`, `TUE`, `WED`, `THU`, `FRI`, `SAT`, `SUN`. The initially deferred clause delays validation of these values until commit time. The order clause ensures the values are sorted by day of week instead of alphabetically when calling `domain_order`.

```
CREATE DOMAIN day_of_week AS CHAR(3 CHAR)
   CONSTRAINT day_of_week_c
     CHECK (day_of_week IN ('MON', 'TUE', 'WED', 'THU', 'FRI', 'SAT', 'SUN'))
   INITIALLY DEFERRED
   ORDER CASE day_of_week
      WHEN 'MON' THEN 0
      WHEN 'TUE' THEN 1
      WHEN 'WED' THEN 2
      WHEN 'THU' THEN 3
      WHEN 'FRI' THEN 4
      WHEN 'SAT' THEN 5
      WHEN 'SUN' THEN 6
      ELSE 7
  END;
```

From 23.3 you can associate columns of data type `CHAR(L CHAR)` with the domain with any value for `L`.

Create Domain email

The following example creates the sequence `email_seq`. It then creates the single column domain `email`. This uses the sequence to generate email addresses in the form

nnn@domain.com when you insert null into columns with this domain, where nnn are the numbers generated by the sequence. The constrains ensures that email addresses are of the form sss@sss.sss, where sss is any nonwhitespace character.

The display clause formats the output of calls to domain_display to ---sss.sss, where sss is the nonwhitespace characters after the @ sign.

```
CREATE SEQUENCE IF NOT EXISTS email_seq;

CREATE DOMAIN email AS VARCHAR2(30)
    DEFAULT ON NULL email_seq.NEXTVAL || '@domain.com'
    CONSTRAINT EMAIL_C CHECK (REGEXP_LIKE (email, '^(\S+)\@(\S+)\.(\S+)$'))
    DISPLAY '---' || SUBSTR(email, INSTR(email, '@') + 1);
```

Create a Strict Domain dept_codes

The following statement creates the domain dept_codes. The check constraint ensures its values are greater than 99 excluding 200. It adds the annotation Title with the value "Domain Annotation". You can only link this domain with columns of type NUMBER(3).

```
CREATE DOMAIN dept_codes AS NUMBER(3) STRICT
      CONSTRAINT dept_chk CHECK (dept_codes > 99 AND dept_codes != 200)
      ANNOTATIONS (Title 'Domain Annotation');
```

Create Domain hourly_wages

The following statement creates the single column domain hourly_wages. It defaults to 15 when inserting null into columns with this domain. The check constraint ensures the values are between 7 and 1,000.

The display clause returns its value in the format $999.99 when calling domain_display. The order clause multiplies its value by negative one, so sorting by domain_order sorts from high to low. It has the annotation Title with the value "Domain Annotation".

```
CREATE DOMAIN hourly_wages AS NUMBER(10)
       DEFAULT ON NULL 15
       CONSTRAINT minimal_wage_c
         CHECK (hourly_wages >= 7 and hourly_wages <=1000) ENABLE
       DISPLAY TO_CHAR(hourly_wages, '$999.99')
       ORDER ( -1*hourly_wages )
       ANNOTATIONS (Title 'Domain Annotation');
```

Add Annotations to a Multi Column Domain US_City at Column and Domain Levels

The following statement creates the multicolumn domain US_city. This has three columns: name, state, and zip. All columns have the Address annotation.

The check constraint ensures that the permitted values for state are CA, AZ, and TX and zip is less than 100000. The display clause returns calls to domain_display in the format name ||', '|| state ||', '||TO_CHAR(zip).

The order clause sorts calls to domain_order by the concatenation of state, then zip, then name. The domain has an object level annotation Title with the value "Domain Annotation" and and three column level annotations Address without a value, one for each column.

```
CREATE DOMAIN US_city AS
  (
    name  AS VARCHAR2(30) ANNOTATIONS (Address),
    state AS VARCHAR2(2) ANNOTATIONS (Address),
```

```
    zip AS NUMBER ANNOTATIONS (Address)
  )
  CONSTRAINT City_CK CHECK(state in ('CA','AZ','TX') and zip < 100000)
  DISPLAY name||', '|| state ||', '||TO_CHAR(zip)
  ORDER state||', '||TO_CHAR(zip)||', '||name
  ANNOTATIONS (Title 'Domain Annotation');
```

Create a Flexible Domain

The following examples create the flexible domain `expense_details`. To do this, you must first create the domains `flight_details`, `meals_details`, and `lodging_details`. These are multicolumn domains with check constraints to ensure the domain columns store appropriate values for the expense type.

For `flight_details`, this means the `flight_num` are two strings separated by a dash, and the origin and destination are both three character strings.

For `meals_details`, the restaurant is mandatory, the `meal_type` one of `Breakfast`, `Lunch` or `Dinner`, and `diner_count` is non-null.

For `lodging_details`, the hotel must be non-null and the `nights_count` greater than zero.

The flexible domain `expense_details` then chooses between these based on the value in the typ column.

In the `FROM DECODE` example:

- if `typ` = `Flight`, it uses the `flight_details` domain. The flexible domain columns `val1`, `val2`, and `val3` map to `flight_num`, `origin`, and `destination` in the `flight_details` domain.
- if `typ` = `Meals`, it uses the `meals_details` domain. The flexible domain columns `val1`, `val2`, and `val4` map to `restaurant`, `meal_type`, and `diner_count` respectively in the `meals_details` domain.
- if `typ` = `Lodging`, it uses the `lodging_details` domain. The flexible domain columns `val1` and `val4` map to `hotel` and `nights_count` respectively in the `lodging_details` domain.

In the `FROM CASE` flexible domain:

- If `typ` starts with letters `A-G`, it uses the `flight_details` domain.
- If `typ` = `Meals`, it uses the `meals_details` domain.
- If typ starts with `Lodg`, it uses the `lodging_details` domain.

The column mappings are the same as in the `FROM DECODE` example.

Create Domain flight_details

```
CREATE DOMAIN flight_details AS
  (
   flight_num AS VARCHAR2(100) NOT NULL,
   origin AS VARCHAR2(200)
     CONSTRAINT origin_3_char_c CHECK (LENGTH(origin) = 3),
   destination AS VARCHAR2(200)
     CONSTRAINT dest_3_char_c CHECK (LENGTH(destination) = 3)
  )
  CONSTRAINT flight_c
    CHECK
      (
        flight_num LIKE '%-%' AND
        origin IS NOT NULL AND
```

```
        destination IS NOT NULL
      )
  CONSTRAINT origin_dest_different_c
    CHECK (origin <> destination)
  DISPLAY flight_num||', '||origin||', '||destination
  ORDER flight_num||destination;
```

Create Domain meals_details

```
CREATE DOMAIN meals_details AS
    (
       restaurant AS VARCHAR2(100) NOT NULL,
       meal_type AS VARCHAR2(200),
       diner_count AS NUMBER
    )
    CONSTRAINT meals_c
      CHECK
       (
         restaurant IS NOT NULL AND
         meal_type IN ('Breakfast', 'Lunch', 'Dinner') AND
         diner_count IS NOT NULL
       )
    DISPLAY meal_type||', '||restaurant||', '||diner_count;
```

Create Domain lodging_details

```
 CREATE DOMAIN lodging_details AS
    (
      hotel AS VARCHAR2(100) NOT NULL,
      nights_count AS NUMBER
    )
    CONSTRAINT lodging_c
     CHECK (hotel IS NOT NULL AND nights_count > 0)
    DISPLAY hotel||', '||nights_count;
```

Create a Flexible Domain expense_details Using FROM DECODE

```
CREATE FLEXIBLE DOMAIN expense_details (val1, val2, val3, val4)
    CHOOSE DOMAIN USING (typ VARCHAR2(10))
    FROM DECODE(typ,
              'Flight', flight_details(val1, val2, val3),
              'Meals', meals_details(val1, val2, val4),
              'Lodging', lodging_details(val1, val4));
```

Create a Flexible Domain expense_details Using FROM CASE

```
CREATE FLEXIBLE DOMAIN expense_details (val1, val2, val3, val4)
    CHOOSE DOMAIN USING(typ VARCHAR2(10))
    FROM CASE
        WHEN typ BETWEEN 'A' AND 'G' THEN flight_details(val1, val2, val3)
        WHEN typ = 'Meals' THEN meals_details(val1, val2, val4)
        WHEN typ LIKE 'Lodg%' THEN lodging_details(val1, val4)
      END;
```

Create Domain Specifying a JSON Schema for Validation

The following example creates domain `w2_form` of type `JSON` with a constraint that checks that the value is a JSON object that complies with the provided JSON Schema. The check constraint uses `IS JSON VALIDATE USING` *`schema_constant_text`*:

```
CREATE DOMAIN w2_form AS JSON
  CONSTRAINT CHECK (VALUE IS JSON VALIDATE USING '{
```

```
    "title": "W2_form",
    "type": "object",
    "properties": {
    "social_security_number": {
    "type": "string",
    "description": "The person social security number."
   },
   "wages": {
     "description": "total wages",
     "type": "number",
     "minimum": 0
   },
   "social_security_wages": {
     "type": "number",
     "description": "wages subject to social security tax"
   },
   "Federal Income Tax Withheld": {
     "type": "number",
     "description": "withheld of tax to federal income tax"
   },
   "Social Security Tax Withheld": {
     "type": "number",
     "description": "withheld of social security tax"
   }
   },
   "required": [
     "social_security_number",
     "wages",
     "Federal Income Tax Withheld"
    ]
   }'
 );
```

The following statement creates table `tax_report` where column `w2_form` is associated with domain `w2_form` to ensure that its content conforms to the schema defined in the domain`w2_form`:

```
CREATE TABLE tax_report(id NUMBER, income JSON DOMAIN w2_form);
```

Before the data is inserted into the income column, it is checked against the JSON Schema. If the data is not valid, an error is raised.

Example of valid data:

```
INSERT INTO tax_report VALUES
  (1, '{"wages": 100, "social_security_number": "111", "Federal Income Tax Withheld":10}'
   );
1 row created
```

Example of invalid data:

```
INSERT INTO tax_report VALUES
  (2, '{"wages": 100}'
   );
ERROR at line 1:
ORA-40875: JSON schema validation error
```

Create a Domain Specifying a JSON Schema Using Shorthand Syntax

```
CREATE DOMAIN w2_form AS JSON VALIDATE USING '{
```

```
  "title": "W2_form",
  "type": "object",
  "properties": {
    "social_security_number": {
    "type": "string",
    "description": "The person social security number."
  },
  "wages": {
    "description": "total wages",
    "type": "number",
    "minimum": 0
  },
  "social_security_wages": {
    "type": "number",
    "description": "wages subject to social security tax"
  },
  "Federal Income Tax Withheld": {
    "type": "number",
    "description": "withheld of tax to federal income tax"
  },
  "Social Security Tax Withheld": {
    "type": "number",
    "description": "withheld of social security tax"
  }
 },
 "required": [
   "social_security_number",
   "wages",
   "Federal Income Tax Withheld"
  ]
 }';
```

Example: Create a Domain with an Annotation Stored as JSON and Query its Value

The following example creates a domain with an annotation `allowed_operations` specified as a JSON string which contains a nested JSON object:

```
CREATE DOMAIN email AS VARCHAR2(30)
    CONSTRAINT EMAIL_C CHECK (REGEXP_LIKE (email, '^(\S+)\@(\S+)\.(\S+)$'))
    DISPLAY '---' || SUBSTR(email, INSTR(email, '@') + 1)
    ANNOTATIONS(allowed_operations
'{
    "allowed_operations": {
        "title": "Allowed operations",
        "operations": [
            "Sort",
            "Group By",
            "Picklist"
        ]
    }
}');
```

Now you can run the following query to retrieve values for the annotation `allowed_operations`:

```
SELECT jt.* FROM user_annotations_usage a,
  JSON_TABLE (annotation_value,
    '$.allowed_operations.operations[*]'
    COLUMNS (value VARCHAR2(50 CHAR) PATH '$')) jt
  WHERE annotation_name = 'ALLOWED_OPERATIONS'
  AND object_name = 'EMAIL' ;
```

The output is:

```
VALUE
----------------------------------------
Sort
Group By
Picklist
```

Example: Create a Domain with an Annotation Stored as JSON and Query its Value

The following example creates a domain with the annotation `display_units` specified as a JSON string containg an array to store the possible display units:

```
CREATE DOMAIN temperature AS NUMBER(3)
ANNOTATIONS (display_units '{ "units": ["celsius", "fahrenheit"] }');
```

Now you can query for the values of the annotation:

```
SELECT jt.* FROM user_annotations_usage,
  JSON_TABLE(annotation_value, '$.units[*]'
    COLUMNS (value VARCHAR2(30 CHAR) PATH '$')) jt
  WHERE annotation_name = 'DISPLAY_UNITS'
  AND object_name = 'TEMPERATURE';
```

The output is:

```
VALUE
-------------------------------------------
celsius
fahrenheit
```

Example: JSON Schema Using a Use Case Domain

You can register a JSON schema as a use case domain.

The following example creates domain `dj5` as a JSON schema object:

```
CREATE DOMAIN dj5 AS JSON CONSTRAINT dj5chk
    CHECK (dj5 IS JSON validate
          '{
           "type": "object",
           "properties": {
             "a": {
               "type": "number"
              }
           }
         }'
    );
```

You can then create a table `jtab` and associate column `jcol` with the domain `dj5`:

```
CREATE TABLE jtab(
      id   NUMBER PRIMARY KEY,
     jcol JSON DOMAIN dj5
    );
```

Examples for ENUM Domains

Example: Create ENUM Domain order_status

The following example creates an enumeration domain `order_status` with a collection of names `New`, `Open`, `Shipped`, `Closed`, `Cancelled`:

```
CREATE DOMAIN order_status AS
  ENUM (
    New ,
    Open ,
    Shipped ,
    Closed ,
    Cancelled
  );
```

Example: Query Enumeration Domain order_status

Unlike a regular domain, the enumeration domain `order_status` can be treated as a table and queried via `SELECT` as follows:

```
SELECT * FROM order_status;
```

The result is:

```
ENUM_NAME     ENUM_VALUE
- - - - -    - - - - - -
NEW                    1
OPEN                   2
SHIPPED                3
CLOSED                 4
CANCELLED              5
```

Example: Enumeration Domain order_status as data type of Column:

Like a regular single-column domain, an enumeration domain can be used to define the data type of a column in a table. In the example below, the enumeration domain `order_status` is used as the data type of column `status` in table `orders`:

```
CREATE TABLE orders (
     id      NUMBER,
     cust    VARCHAR2(100),
     status  ORDER_STATUS
);
```

Using `DESCRIBE` on the `orders` table shows the `status` column as a numeric column with a single column domain `order_status`:

```
DESCRIBE orders;
```

The result is:

```
Name    Null ?  Type
----    ------  ----
ID              NUMBER
CUST            VARCHAR2 (100)
STATUS          NUMBER SCOTT.ORDER_STATUS
```

You can construct each row to insert into the the `orders` table using the appropriate `order_status`:

```
INSERT INTO orders VALUES
  (1, 'Costco', order_status.open ),
  (2, 'BMW', order_status.closed ),
  (3, 'Nestle', order_status.shipped );

 3 rows created .
```

Use the `domain_display` function to list the rows in the `orders` table:

```
SELECT ID, DOMAIN_DISPLAY(STATUS) FROM orders;
```

The result is:

```
ID        STATUS
---       ------
1         OPEN
2         CLOSED
3         SHIPPED
```

The actual values stored in the status column are the values you associated with the status when you created the enumerated domain `order_status`, 2 for `OPEN`, 4 for `CLOSED`, and 3 for `SHIPPED`:

```
SELECT ID, STATUS FROM orders;
```

The result is:

```
ID        STATUS
---       ------
1         2
2         4
3         3
```

Since the underlying data type of the status column is a number, you can directly update the column with a numeric value as long as is passes the domain check-constraint:

```
UPDATE orders SET STATUS = 2 WHERE STATUS = 5;

1 ROW UPDATED.
```

Since enumeration names are placeholds for literal values, you can use them anywhere where SQL allows literals:

```
SELECT 2 * ORDER_STATUS.CANCELLED;
```

The result is:

```
2*ORDER_STATUS.CANCELLED
------------------------
                      10
```

Example: Create ENUM Domain days_of_week

The following example creates an enumeration domain `days_of_week` with a collection of names that comprises the days of the week.

Each value has a pair of names, only the first name of the pair has an assigned value. There are two names for each value, the full day name and the first two letters of the day's name. The names `Sunday` and `Su` both have the value zero. The value then increases by one for each pair of names. So `Monday` and `Mo` have the value 1, `Tuesday` and `Tu` have the value 2 and so on up to `Saturday` and `Sa` which have the value 6.

```
CREATE DOMAIN days_of_week AS
  ENUM (
    Sunday     = Su  = 0,
    Monday     = Mo,
    Tuesday    = Tu,
    Wednesday  = We,
    Thursday   = Th,
    Friday     = Fr,
    Saturday   = Sa
  );
```

CREATE EDITION

Purpose

This statement creates a new edition as a child of an existing edition. An edition makes it possible to have two or more versions of the same editionable objects in the database. When you create an edition, it immediately inherits all of the editionable objects of its parent edition. The following object types are editionable:

- Synonym
- View
- Function
- Procedure
- Package (specification and body)
- Type (specification and body)
- Library
- Trigger

An editionable object is an object of one of the above editionable object types in an editions-enabled schema. The ability to have multiple versions of these objects in the database greatly facilitates online application upgrades.

> **Note:**
>
> All database object types not listed above are not editionable. Changes to object types that are not editionable are immediately visible across all editions in the database.

Every newly created or upgraded Oracle Database has one default edition named `ORA$BASE`, which serves as the parent of the first edition created with a `CREATE EDITION` statement. You can subsequently designate a user-defined edition as the database default edition using an `ALTER DATABASE DEFAULT EDITION` statement.

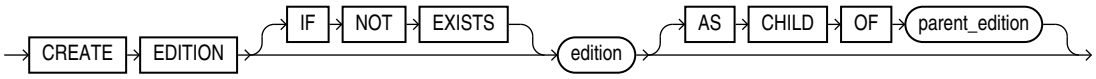
> **See Also:**
>
> - *Oracle Database Development Guide* for a more complete discussion of editionable object types and editions
> - The `ALTER DATABASE` "DEFAULT EDITION Clause" for information on designating an edition as the default edition for the database

Prerequisites

To create an edition, you must have the `CREATE ANY EDITION` system privilege, granted either directly or through a role. To create an edition as a child of another edition, you must have the `USE` object privilege on the parent edition.

Syntax

***create_edition*::=**



Semantics

edition

Specify the name of the edition to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

To view the editions that have been created for the database, query the `EDITION_NAME` column of the `DBA_OBJECTS` or `ALL_OBJECTS` data dictionary view.

When you create an edition, the system automatically grants you the `USE` object privilege `WITH GRANT OPTION` on the edition you create.

> **Note:**
>
> Oracle strongly recommends that you do not name editions with the prefixes `ORA`, `ORACLE`, `SYS`, `DBA`, and `DBMS`, as these prefixes are reserved for internal use.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the object does not exist, a new obejct is created at the end of the statement.
- If the object exists, this is the object you have at the end of the statement. A new one is not created because the older object is detected.

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

AS CHILD OF Clause

If you use this clause, then the new edition is created as a child of *parent_edition*. If you omit this clause, then the new edition is created as a child of the leaf edition. At the time of its creation, the new edition inherits all editioned objects from its parent edition.

Restriction on Editions

An edition can have only one child edition. If you specify for *parent_edition* an edition that already has a child edition, then an error is returned.

Examples

The following very simple examples are intended to show the syntax for creating and working with an edition. For realistic examples of using editions refer to *Oracle Database Development Guide*.

In the following statements, the user HR is given the privileges needed to create and use an edition:

```
GRANT CREATE ANY EDITION, DROP ANY EDITION to HR;
Grant succeeded.

ALTER USER hr ENABLE EDITIONS;
User altered.
```

HR creates a new edition TEST_ED for testing purposes:

```
CREATE EDITION test_ed;
```

HR then creates an editioning view ed_view in the default edition ORA$BASE for testing purposes, first verifying that the current edition is the default edition:

```
SELECT SYS_CONTEXT('userenv', 'current_edition_name') FROM DUAL;
SYS_CONTEXT('USERENV','CURRENT_EDITION_NAME')
--------------------------------------------------------------------------------
ORA$BASE
1 row selected.

CREATE EDITIONING VIEW e_view AS
  SELECT last_name, first_name, email FROM employees;
View created.

DESCRIBE e_view
 Name                                    Null?    Type
 ----------------------------------------- -------- ----------------------------
 LAST_NAME                               NOT NULL VARCHAR2(25)
 FIRST_NAME                                       VARCHAR2(20)
 EMAIL                                   NOT NULL VARCHAR2(25)
```

The view is then actualized in the TEST_ED edition when HR uses the TEST_ED edition and re-creates the view in a different form:

```
ALTER SESSION SET EDITION = TEST_ED;
Session altered.

CREATE OR REPLACE EDITIONING VIEW e_view AS
  SELECT last_name, first_name, email, salary FROM employees;

View created.
```

The view in the TEST_ED edition has an additional column:

```
DESCRIBE e_view
 Name                                      Null?    Type
 ----------------------------------------- -------- ----------------------------
 LAST_NAME                                 NOT NULL VARCHAR2(25)
 FIRST_NAME                                         VARCHAR2(20)
 EMAIL                                     NOT NULL VARCHAR2(25)
 SALARY                                             NUMBER(8,2)
```

The view in the ORA$BASE edition remains isolated from the test environment:

```
ALTER SESSION SET EDITION = ora$base;
Session altered.

DESCRIBE e_view;

 Name                                      Null?    Type
 ----------------------------------------- -------- ----------------------------
 LAST_NAME                                 NOT NULL VARCHAR2(25)
 FIRST_NAME                                         VARCHAR2(20)
 EMAIL                                     NOT NULL VARCHAR2(25)
```

Even if the view is dropped in the test environment, it remains in the ORA$BASE edition:

```
ALTER SESSION SET EDITION = TEST_ED;
Session altered.

DROP VIEW e_view;
View dropped.

ALTER SESSION SET EDITION = ORA$BASE;
Session altered.

DESCRIBE e_view;
 Name                                      Null?    Type
 ----------------------------------------- -------- ----------------------------
 LAST_NAME                                 NOT NULL VARCHAR2(25)
 FIRST_NAME                                         VARCHAR2(20)
 EMAIL                                     NOT NULL VARCHAR2(25)
```

When the testing of upgrade that necessitated the TEST_ED edition is complete, the edition can be dropped:

```
DROP EDITION TEST_ED;
```

CREATE FLASHBACK ARCHIVE

Purpose

Use the CREATE FLASHBACK ARCHIVE statement to create a flashback archive, which provides the ability to automatically track and archive transactional data changes to specified database objects. A flashback archive consists of multiple tablespaces and stores historic data from all transactions against tracked tables. The data is stored in internal history tables.

Flashback data archives retain historical data for the time duration specified using the RETENTION parameter. Historical data can be queried using the Flashback Query AS OF clause. Archived historic data that has aged beyond the specified retention period is automatically purged.

Flashback data archives retain historical data across data definition language (DDL) changes to tables enabled for flashback archive. Flashback data archives supports many common DDL statements, including some DDL statements that alter table definitions or incur data movement. DDL statements that are not supported result in error ORA-55610.

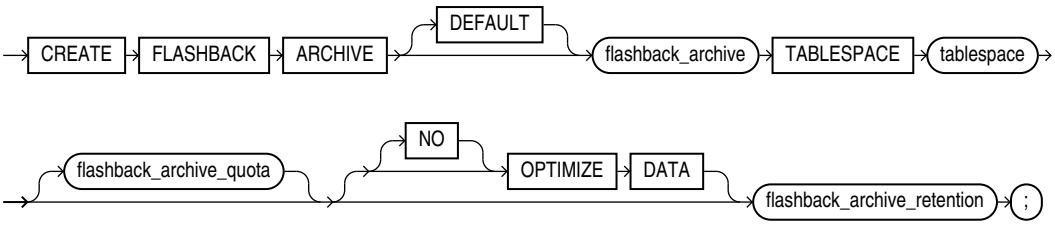
> **See Also:**
>
> - *Oracle Database Development Guide* for general information on using Flashback Time Travel
> - The `CREATE TABLE` *flashback_archive_clause* for information on designating a table as a tracked table
> - ALTER FLASHBACK ARCHIVE for information on changing the quota and retention attributes of the flashback archive, as well as adding or changing tablespace storage for the flashback archive

Prerequisites

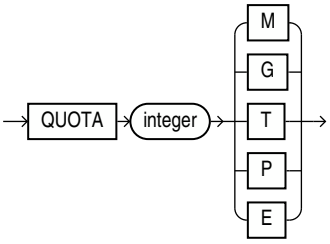
You must have the `FLASHBACK ARCHIVE ADMINISTER` system privilege to create a flashback archive. In addition, you must have the `CREATE TABLESPACE` system privilege to create a flashback archive, as well as sufficient quota on the tablespace in which the historical information will reside. To designate a flashback archive as the system default flashback archive, you must be logged in as `SYSDBA`.

Syntax

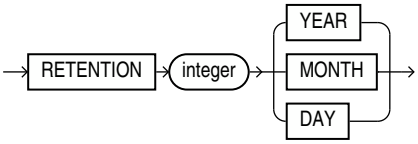
***create_flashback_archive*::=**



***flashback_archive_quota*::=**



***flashback_archive_retention*::=**



Semantics

DEFAULT

You must be logged in as `SYSDBA` to specify `DEFAULT`. Use this clause to designate this flashback archive as the default flashback archive for the database. When a `CREATE TABLE` or `ALTER TABLE` statement specifies the *`flashback_archive_clause`* without specifying a flashback archive name, the database uses the default flashback archive to store data from that table.

You cannot specify this clause if a default flashback archive already exists. However, you can replace an existing default flashback archive using the `ALTER FLASHBACK ARCHIVE ... SET DEFAULT` clause.

> **See Also:**
>
> The `CREATE TABLE` *flashback_archive_clause* for more information

flashback_archive

Specify the name of the flashback archive. The name must satisfy the requirements specified in "Database Object Naming Rules ".

TABLESPACE Clause

Specify the tablespace where the archived data for this flashback archive is to be stored. You can specify only one tablespace with this clause. However, you can subsequently add tablespaces to the flashback archive with an `ALTER FLASHBACK ARCHIVE` statement.

flashback_archive_quota

Specify the amount of space in the initial tablespace to be reserved for the archived data. If the space for archiving in a flashback archive becomes full, then DML operations on tracked tables that use this flashback archive will fail. The database issues an out-of-space alert when the content of the flashback archive is 90% of the specified quota, to allow time to purge old data or add additional quota. If you omit this clause, then the flashback archive has unlimited quota on the specified tablespace.

[NO] OPTIMIZE DATA

Specify `OPTIMIZE DATA` to enable optimization for flashback archive history tables. This instructs the database to optimize the storage of data in history tables using any of the following features: Advanced Row Compression, Advanced LOB Compression, Advanced LOB Deduplication, segment-level compression tiering, and row-level compression tiering. To specify this clause, you must have a license for the Advanced Compression option.

Specify `NO OPTIMIZE DATA` to instruct the database not to optimize the storage of data in history tables. This is the default.

flashback_archive_retention

Specify the length of time in months, days, or years that the archived data should be retained in the flashback archive. If the length of time causes the flashback archive to become full, then the database responds as described in *flashback_archive_quota*.

Examples

The following statement creates two flashback archives for testing purposes. The first is designated as the default for the database. For both of them, the space quota is 1 megabyte, and the archive retention is one day.

```
CREATE FLASHBACK ARCHIVE DEFAULT test_archive1
   TABLESPACE example
   QUOTA 1 M
   RETENTION 1 DAY;

CREATE FLASHBACK ARCHIVE test_archive2
   TABLESPACE example
   QUOTA 1 M
   RETENTION 1 DAY;
```

The next statement alters the default flashback archive to extend the retention period to 1 month:

```
ALTER FLASHBACK ARCHIVE test_archive1
   MODIFY RETENTION 1 MONTH;
```

The next statement specifies tracking for the `oe.customers` table. The flashback archive is not specified, so data will be archived in the default flashback archive, `test_archive1`:

```
ALTER TABLE oe.customers
   FLASHBACK ARCHIVE;
```

The next statement specifies tracking for the `oe.orders` table. In this case, data will be archived in the specified flashback archive, `test_archive2`:

```
ALTER TABLE oe.orders
   FLASHBACK ARCHIVE test_archive2;
```

The next statement drops `test_archive2` flashback archive:

```
DROP FLASHBACK ARCHIVE test_archive2;
```

CREATE FUNCTION

Purpose

Functions are defined in PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `CREATE FUNCTION` statement to create a standalone stored function or a call specification.

- A **stored function** (also called a **user function** or **user-defined function**) is a set of PL/SQL statements you can call by name. Stored functions are very similar to procedures,

except that a function returns a value to the environment in which it is called. User functions can be used as part of a SQL expression.

- A **call specification** declares a JavaScript method, a Java method or a third-generation language (3GL) routine so that it can be called from PL/SQL. You can also use the `CALL` SQL statement to call such a method or routine. The call specification tells Oracle Database which Java method, JavaScript method, or which named function in which shared library, to invoke when a call is made. It also tells the database what type conversions to make for the arguments and return value.

> **Note:**
>
> You can also create a function as part of a package using the `CREATE PACKAGE` statement.

> **See Also:**
>
> - CREATE PROCEDURE for a general discussion of procedures and functions, CREATE PACKAGE for information on creating packages, ALTER FUNCTION and DROP FUNCTION for information on modifying and dropping a function
> - CREATE LIBRARY for information on shared libraries
> - *Oracle Database Development Guide* for more information about registering external functions
> - *JavaScript Developer's Guide*
> - CREATE MLE MODULE

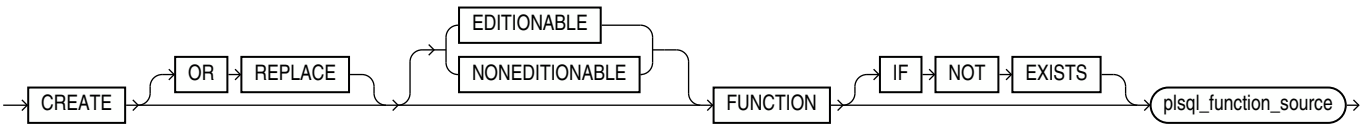
Prerequisites

To create or replace a function in your own schema, you must have the `CREATE PROCEDURE` system privilege. To create or replace a function in another user's schema, you must have the `CREATE ANY PROCEDURE` system privilege.

Syntax

Functions are defined using PL/SQL. Alternatively they can refer to non-PL/SQL code such as Java, JavaScript, C, and others by means of call specifications. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

***create_function*::=**



(*plsql_function_source*: See *Oracle Database PL/SQL Language Reference*.)

Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the function if it already exists. Use this clause to change the definition of an existing function without dropping, re-creating, and regranting object privileges previously granted on the function. If you redefine a function, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined function can still access the function without being regranted the privileges.

If any function-based indexes depend on the function, then Oracle Database marks the indexes `DISABLED`.

> **See Also:**
>
> `ALTER FUNCTION` for information on recompiling functions using SQL

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the function does not exist, a new function is created at the end of the statement.
- If the function exists, this is the function you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement`.

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement`.

[EDITIONABLE | NONEDITIONABLE]

Use these clauses to specify whether the function is an editioned or noneditioned object if editioning is enabled for the schema object type `FUNCTION` in *`schema`*. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

plsql_function_source

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the *`plsql_function_source`*, including examples.

CREATE HIERARCHY

Purpose

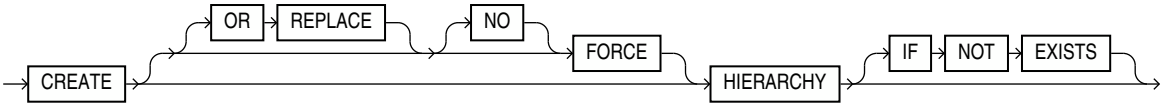
Use the `CREATE HIERARCHY` statement to create a hierarchy. A hierarchy specifies the hierarchical relationships among the levels of an attribute dimension.

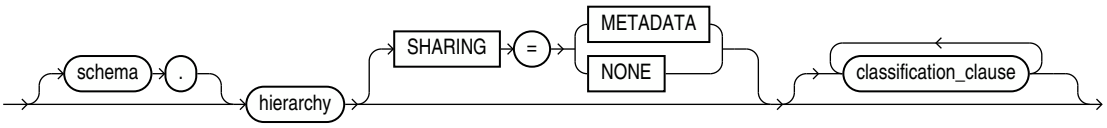
Prerequisites

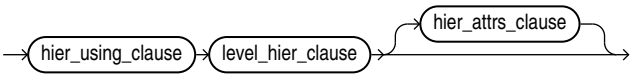
To create a hierarchy in your own schema, you must have the `CREATE HIERARCHY` system privilege. To create a hierarchy in another user's schema, you must have the `CREATE ANY HIERARCHY` system privilege.

Syntax

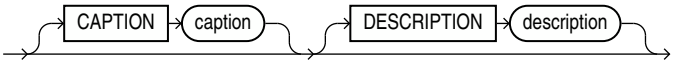
***create_hierarchy*::=**

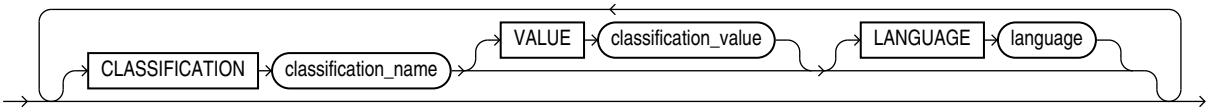




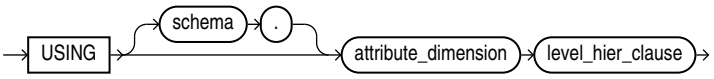


***classification_clause*::=**

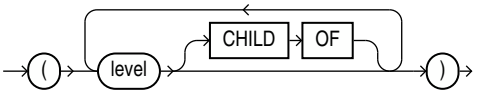




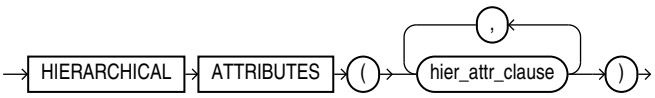
***hier_using_clause*::=**



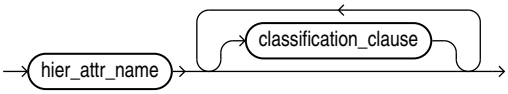
***level_hier_clause*::=**



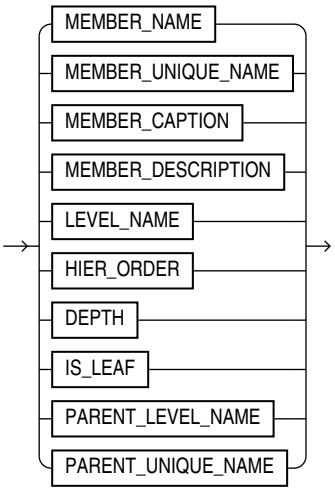
***hier_attrs_clause*::=**



***hier_attr_clause*::=**



***hier_attr_name*::=**



Semantics

OR REPLACE

Specify `OR REPLACE` to replace an existing definition of a hierarchy with a different definition.

FORCE and NOFORCE

Specify `FORCE` to force the creation of the hierarchy even if it does not successfully compile. If you specify `NOFORCE`, then the hierarchy must compile successfully, otherwise an error occurs. The default is `NOFORCE`.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the hierarchy does not exist, a new hierarchy is created at the end of the statement.
- If the hierarchy exists, this is the hierarchy you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

schema

Specify the schema in which to create the hierarchy. If you do not specify a schema, then Oracle Database creates the hierarchy in your own schema.

hierarchy

Specify a name for the hierarchy.

SHARING

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- `METADATA` - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- `NONE` - The object is not shared and can only be accessed in the application root.

classification_clause

Use the classification clause to specify values for the `CAPTION` or `DESCRIPTION` classifications and to specify user-defined classifications. Classifications provide descriptive metadata that applications may use to provide information about analytic views and their components.

You may specify any number of classifications for the same object. A classification can have a maximum length of 4000 bytes.

For the `CAPTION` and `DESCRIPTION` classifications, you may use the DDL shortcuts `CAPTION '`*`caption`*`'` and `DESCRIPTION '`*`description`*`'` or the full classification syntax.

You may vary the classification values by language. To specify a language for the `CAPTION` or `DESCRIPTION` classification, you must use the full syntax. If you do not specify a language, then the language value for the classification is `NULL`. The language value must either be `NULL` or a valid `NLS_LANGUAGE` value.

hier_using_clause

Specify the attribute dimension that has the members of the hierarchy.

level_hier_clause

Specify the organization of the hierarchy levels.

hier_attrs_clause

Specify classifications that contain descriptive metadata for the hierarchical attributes. A *`hier_attr_clause`* for a given *`hier_attr_name`* may appear only once in the list.

All hierarchies always contain all of the hierarchical attributes, but a hierarchical attribute does not have descriptive metadata associated with it unless you specify it with this clause.

hier_attr_clause

Specify a hierarchical attribute and provide one or more classifications for it.

hier_attr_name

Specify a hierarchical attribute.

Examples

The following example creates the `TIME_HIER` hierarchy:

```
CREATE OR REPLACE HIERARCHY time_hier  -- Hierarchy name
USING time_attr_dim               -- Refers to TIME_ATTR_DIM attribute
dimension
 (month CHILD OF                  -- Months in the attribute dimension
 quarter CHILD OF
 year);
```

The following example creates the `PRODUCT_HIER` hierarchy:

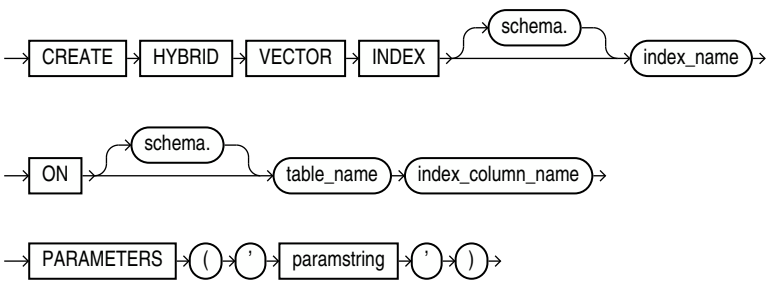
```
CREATE OR REPLACE HIERARCHY product_hier
USING product_attr_dim
 (category
  CHILD OF department);
```

The following example creates the `GEOGRAPHY_HIER` hierarchy:

```
CREATE OR REPLACE HIERARCHY geography_hier
USING geography_attr_dim
 (state_province
  CHILD OF country
  CHILD OF region);
```

CREATE HYBRID VECTOR INDEX

Syntax



Semantics

This command is part of the Oracle Text product.

Use the `CREATE HYBRID VECTOR INDEX` statement to create a hybrid vector index, which allows you to index and query documents using a combination of full-text search and similarity search to achieve higher quality search results.

Hybrid Vector Index for JSON

You can create a hybrid vector index on a JSON column. In this case *`index_column_name`* must be a column of type `JSON`, and *`paramstring`* must contain the JSON-specific path element.

> **See Also:**
>
> - For full semantics and usage details, refer to Oracle Text SQL Statements and Operators of the *Oracle Text Reference*.
> - Indexes for JSON DATA

CREATE INDEX

Purpose

Use the `CREATE INDEX` statement to create an index on:

- One or more columns of a table, a partitioned table, an index-organized table, or a cluster
- One or more scalar typed object attributes of a table or a cluster
- A nested table storage table for indexing a nested table column

An **index** is a schema object that contains an entry for each value that appears in the indexed column(s) of the table or cluster and provides direct, fast access to rows. The maximum size of a single index entry is dependent on the block size of the database.

Oracle Database supports several types of index:

- **Normal indexes.** (By default, Oracle Database creates B-tree indexes.)
- **Bitmap indexes**, which store rowids associated with a key value as a bitmap.
- **Partitioned indexes**, which consist of partitions containing an entry for each value that appears in the indexed column(s) of the table.
- **Function-based indexes**, which are based on expressions. They enable you to construct queries that evaluate the value returned by an expression, which in turn may include built-in or user-defined functions.
- **Domain indexes**, which are instances of an application-specific index of type *`indextype`*.

Note:

- *Oracle Database Concepts* for a discussion of indexes
- *Oracle Database Reference* for more information about the limits related to index size
- *Oracle Database Reference* for information on how index creation inherits compression attributes
- ALTER INDEX and DROP INDEX

Prerequisites

To create an index in your own schema, one of the following conditions must be true:

- The table or cluster to be indexed must be in your own schema.
- You must have the `INDEX` object privilege on the table to be indexed.
- You must have the `CREATE ANY INDEX` system privilege.

To create an index in another schema, you must have the `CREATE ANY INDEX` system privilege. Also, the owner of the schema to contain the index must have either the `UNLIMITED TABLESPACE` system privilege or space quota on the tablespaces to contain the index or index partitions.

To create a function-based index, in addition to the prerequisites for creating a conventional index, if the index is based on user-defined functions, then those functions must be marked `DETERMINISTIC`. A function-based index is executed with the credentials of the index owner, so the index owner must have the `EXECUTE` object privilege on the function.

To create a domain index in your own schema, in addition to the prerequisites for creating a conventional index, you must also have the `EXECUTE` object privilege on the indextype. If you are creating a domain index in another user's schema, then the index owner also must have the `EXECUTE` object privilege on the indextype and its underlying implementation type. Before creating a domain index, you should first define the indextype.

Semantics

UNIQUE

Specify `UNIQUE` to indicate that the value of the column (or columns) upon which the index is based must be unique.

Restrictions on Unique Indexes

Unique indexes are subject to the following restrictions:

- You cannot specify both `UNIQUE` and `BITMAP`.
- You cannot specify `UNIQUE` for a domain index.

> **See Also:**
>
> "Unique Constraints " for information on the conditions that satisfy a unique constraint

BITMAP

Specify `BITMAP` to indicate that *`index`* is to be created with a bitmap for each distinct key, rather than indexing each row separately. Bitmap indexes store the rowids associated with a key value as a bitmap. Each bit in the bitmap corresponds to a possible rowid. If the bit is set, then it means that the row with the corresponding rowid contains the key value. The internal representation of bitmaps is best suited for applications with low levels of concurrent transactions, such as data warehousing.

> **Note:**
>
> Oracle does not index table rows in which all key columns are null except in the case of bitmap indexes. Therefore, if you want an index on all rows of a table, then you must either specify `NOT NULL` constraints for the index key columns or create a bitmap index.

Restrictions on Bitmap Indexes

Bitmap indexes are subject to the following restrictions:

- You cannot specify `BITMAP` when creating a global partitioned index.
- You cannot create a bitmap secondary index on an index-organized table unless the index-organized table has a mapping table associated with it.
- You cannot specify both `UNIQUE` and `BITMAP`.
- You cannot specify `BITMAP` for a domain index.
- A bitmap index can have a maximum of 30 columns.

> **See Also:**
>
> - *Oracle Database Concepts* and *Oracle Database SQL Tuning Guide* for more information about using bitmap indexes
> - CREATE TABLE for information on mapping tables
> - "Bitmap Index Examples"

MULTIVALUE

Use the `MULTIVALUE` keyword to create a multivalue index on JSON data using simple dot-notation syntax to specify the path to the indexed data.

Example

The multivalue index created here indexes the values of top-level field `credit_score`. If the `credit_score` value targeted by a query is an array, then the index can be picked up for any array elements that are numbers. If the value is a scalar, then the index can be picked up if the scalar is a number.

```
CREATE MULTIVALUE INDEX mvi_1 ON mytable t
      (t.jcol.credit_score.numberOnly());
```

> **See Also:**
>
> - Indexes for JSON Data
> - Simple Dot-Notation Access to JSON Data

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the index does not exist, a new index is created at the end of the statement.
- If the index exists, this is the index you have at the end of the statement. A new one is not created because the older index is detected.

Using `IF EXISTS` with `CREATE INDEX` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement`.

schema

Specify the schema to contain the index. If you omit *schema*, then Oracle Database creates the index in your own schema.

index_name

Specify the name of the index to be created. The name must satisfy the requirements listed in Database Object Naming Rules .

> **See Also:**
>
> Creating an Index: Example and Creating an Index on an XMLType Table: Example

index_ilm_clause

With Oracle Database Release 20c you can use the *index_ilm_clause* to add or delete an ILM policy to an index.

You can also add an ILM policy to an index after you create it with the `ALTER INDEX` statement.

When you create an index with an ILM policy, you can add only one new policy. To add more policies to an index, or to modify existing policies on the index you must use the `ALTER INDEX` statement.

You cannot modify an ILM policy at the index partition level. The index level modification will be cascaded to all partitions.

Examples

```
CREATE INDEX [schema.]empno_idx ILM_POLICY
```

Restrictions

You cannot add an ILM policy on cluster indexes and IOTs.

You cannot add an ILM policy on domain indexes and bitmap indexes.

policy_clause

The `OPTIMIZE` index policy chooses the appropriate action if the policy condtion is met.

You can create ILM policies on objects in the same schema.

If you want to move the ILM policy to a different tablespace, you must ensure that you have the necessary permissions for all the tablespaces mentioned in the ILM policy.

You must also ensure that you have the necessary storage on the target tablespaces for storage tiering jobs.

cluster_index_clause

Use the *cluster_index_clause* to identify the cluster for which a cluster index is to be created. If you do not qualify cluster with *schema*, then Oracle Database assumes the cluster is in your current schema. You cannot create a cluster index for a hash cluster.

> **See Also:**
>
> CREATE CLUSTER and "Creating a Cluster Index: Example"

table_index_clause

Specify the table on which you are defining the index. If you do not qualify *table* with *schema*, then Oracle Database assumes the table is contained in your own schema.

You create an index on a nested table column by creating the index on the nested table storage table. Include the NESTED_TABLE_ID pseudocolumn of the storage table to create a UNIQUE index, which effectively ensures that the rows of a nested table value are distinct.

> **See Also:**
>
> "Indexes on Nested Tables: Example"

You can perform DDL operations (such as ALTER TABLE, DROP TABLE, CREATE INDEX) on a temporary table only when no session is bound to it. A session becomes bound to a temporary table by performing an INSERT operation on the table. A session becomes unbound to the temporary table by issuing a TRUNCATE statement or at session termination, or, for a transaction-specific temporary table, by issuing a COMMIT or ROLLBACK statement.

Restrictions on the *table_index_clause*

This clause is subject to the following restrictions:

- If *index* is locally partitioned, then *table* must be partitioned.
- If *table* is index-organized, then this statement creates a secondary index. The index contains the index key and the logical rowid of the index-organized table. The logical rowid excludes columns that are also part of the index key. You cannot specify REVERSE for this secondary index, and the combined size of the index key and the logical rowid should be less than the block size.
- If *table* is a temporary table, then *index* will also be temporary with the same scope (session or transaction) as *table*. The following restrictions apply to indexes on temporary tables:
  - The only part of *index_properties* you can specify is *index_attributes*.
  - Within *index_attributes*, you cannot specify the *physical_attributes_clause*, the *parallel_clause*, the *logging_clause*, or TABLESPACE.
  - You cannot create a domain index or a partitioned index on a temporary table.

- You cannot create an index on an external table.

> **See Also:**
>
> CREATE TABLE and *Oracle Database Concepts* for more information on temporary tables

t_alias

Specify a correlation name (alias) for the table upon which you are building the index.

> **Note:**
>
> This alias is required if the *index_expr* references any object type attributes or object type methods. See "Creating a Function-based Index on a Type Method: Example" and "Indexing on Substitutable Columns: Examples".

index_expr

For *index_expr*, specify the column or column expression upon which the index is based.

You can create multiple indexes on the same set of columns, column expressions, or both if the following conditions are met:

- The indexes are of different types, use different partitioning, or have different uniqueness properties.
- Only one of the indexes is `VISIBLE` at any given time.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information on creating multiple indexes

column

Specify the name of one or more columns in the table. A bitmap index can have a maximum of 30 columns. Other indexes can have as many as 32 columns. These columns define the **index key**.

If a unique index is local nonprefixed (see *local_partitioned_index*), then the index key must contain the partitioning key.

> **See Also:**
>
> *Oracle Database VLDB and Partitioning Guide* for information on prefixed and nonprefixed indexes

You can create an index on a scalar object attribute column or on the system-defined NESTED_TABLE_ID column of the nested table storage table. If you specify an object attribute column, then the column name must be qualified with the table name. If you specify a nested table column attribute, then it must be qualified with the outermost table name, the containing column name, and all intermediate attribute names leading to the nested table column attribute.

When you create an index on a column or expression with a declared or derived named collation other than BINARY, or a declared or derived pseudo-collation USING_NLS_SORT_CI or USING_NLS_SORT_AI, the database creates a functional index on the function NLSSORT. See *Oracle Database Globalization Support Guide* for more information.

Creating an Index on an Extended Data Type Column

If *column* is an extended data type column, then you may receive a "maximum key length exceeded" error when attempting to create the index. The maximum key length for an index varies depending on the database block size and some additional index metadata stored in a block. For example, for databases that use the Oracle standard 8K block size, the maximum key length is approximately 6400 bytes.

To work around this situation, you must shorten the length of the values you want to index, using one of the following methods:

- Create a function-based index to shorten the values stored in the extended data type column as part of the expression used for the index definition.
- Create a virtual column to shorten the values stored in the extended data type column as part of the expression used for the virtual column definition and build a normal index on the virtual column. Using a virtual column also enables you to leverage functionality for regular columns, such as collecting statistics and using constraint and triggers.

For both methods you can use either the SUBSTR or STANDARD_HASH function to shorten the values of the extended data type column to build an index. These methods have the following advantages and disadvantages:

- Use the SUBSTR function to return a substring, or prefix, of *column* that is an acceptable length for the index key. This type of index can be used for equality, IN-list, and range predicates on the original column without the need to specify the SUBSTR column as part of the predicate. Refer to SUBSTR for more information.
- Using the STANDARD_HASH function is likely to create an index that is more compact than the substring-based index and may result in fewer unnecessary index accesses. This type of index can be used for equality and IN-list predicates on the original column without the need to specify the STANDARD_HASH column as part of the predicate. Refer to STANDARD_HASH for more information.

The following example shows how to create a function-based index on an extended data type column:

```
CREATE INDEX index ON table (SUBSTR(column, 1, n));
```

For n, specify a prefix length that is large enough to differentiate between values in *column*.

The following example shows how to create a virtual column for an extended data type column, and then create an index on the virtual column:

```
ALTER TABLE table ADD (new_hash_column AS (STANDARD_HASH(column)));
CREATE INDEX index ON table (new_hash_column);
```

> **See Also:**
>
> "Extended Data Types" for more information on extended data types

Restrictions on Index Columns

The following restrictions apply to index columns:

- You cannot create an index on columns or attributes whose type is user-defined, `LONG`, `LONG RAW`, LOB, or `REF`, except that Oracle Database supports an index on `REF` type columns or attributes that have been defined with a `SCOPE` clause.
- Only normal (B-tree) indexes can be created on encrypted columns, and they can only be used for equality searches.

column_expression

Specify an expression built from columns of *table*, constants, SQL functions, and user-defined functions. When you specify *column_expression*, you create a **function-based index**.

> **See Also:**
>
> "Column Expressions ", "Notes on Function-based Indexes", "Restrictions on Function-based Indexes", and "Function-Based Index Examples"

Name resolution of the function is based on the schema of the index creator. User-defined functions used in *column_expression* are fully name resolved during the `CREATE INDEX` operation.

After creating a function-based index, collect statistics on both the index and its base table using the `DBMS_STATS` package. Such statistics will enable Oracle Database to correctly decide when to use the index.

Function-based unique indexes can be useful in defining a conditional unique constraint on a column or combination of columns. Refer to "Using a Function-based Index to Define Conditional Uniqueness: Example" for an example.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for more information on the `DBMS_STATS` package

Notes on Function-based Indexes

The following notes apply to function-based indexes:

- When you subsequently query a table that uses a function-based index, Oracle Database will not use the index unless the query filters out nulls. However, Oracle Database will use a function-based index in a query even if the columns specified in the `WHERE` clause are in a different order than their order in the *column_expression* that defined the function-based index.

> **See Also:**
>
> "Function-Based Index Examples"

- If the function on which the index is based becomes invalid or is dropped, then Oracle Database marks the index `DISABLED`. Queries on a `DISABLED` index fail if the optimizer chooses to use the index. DML operations on a `DISABLED` index fail unless the index is also marked `UNUSABLE` **and** the parameter `SKIP_UNUSABLE_INDEXES` is set to `true`. Refer to ALTER SESSION for more information on this parameter.
- If a public synonym for a function, package, or type is used in *`column_expression`*, and later an actual object with the same name is created in the table owner's schema, then Oracle Database disables the function-based index. When you subsequently enable the function-based index using `ALTER INDEX ... ENABLE` or `ALTER INDEX ... REBUILD`, the function, package, or type used in the *`column_expression`* continues to resolve to the function, package, or type to which the public synonym originally pointed. It will not resolve to the new function, package, or type.
- If the definition of a function-based index generates internal conversion to character data, then use caution when changing NLS parameter settings. Function-based indexes use the current database settings for NLS parameters. If you reset these parameters at the session level, then queries using the function-based index may return incorrect results. Two exceptions are the collation parameters (`NLS_SORT` and `NLS_COMP`). Oracle Database handles the conversions correctly even if these have been reset at the session level.
- Oracle Database cannot convert data in all cases, even when conversion is explicitly requested. For example, an attempt to convert the string `'105 lbs'` from `VARCHAR2` to `NUMBER` using the `TO_NUMBER` function fails with an error. Therefore, if *`column_expression`* contains a data conversion function such as `TO_NUMBER` or `TO_DATE`, and if a subsequent `INSERT` or `UPDATE` statement includes data that the conversion function cannot convert, then the index will cause the `INSERT` or `UPDATE` statement to fail.
- If *`column_expression`* contains a datetime format model, then the function-based index expression defining the column may contain format elements that are different from those specified. For example, define a function-based index using the `yyyy` datetime format element:

  ```
  CREATE INDEX cust_eff_ix ON customers
    (NVL(cust_eff_to, TO_DATE('9000-01-01 00:00:00', 'yyyy-mm-dd hh24:mi:ss')));
  ```

  Query the `ALL_IND_EXPRESSIONS` view to see that the function-based index expression defining the column uses the `syyyy` datetime format element:

  ```
  SELECT column_expression
    FROM all_ind_expressions
    WHERE index_name='CUST_EFF_IX';

  COLUMN_EXPRESSION
  --------------------------------------------------------------------------------
  NVL("CUST_EFF_TO",TO_DATE(' 9000-01-01 00:00:00', 'syyyy-mm-dd hh24:mi:ss'))
  ```

Restrictions on Function-based Indexes

Function-based indexes are subject to the following restrictions:

- The value returned by the function referenced in *`column_expression`* is subject to the same restrictions as are the index columns of a B-tree index. Refer to "Restrictions on Index Columns".

- Any user-defined function referenced in *column_expression* must be declared as DETERMINISTIC.
- For a function-based globally partitioned index, the *column_expression* cannot be the partitioning key.
- The *column_expression* can be any of the forms of expression described in Column Expressions .
- All functions must be specified with parentheses, even if they have no parameters. Otherwise Oracle Database interprets them as column names.
- Any function you specify in *column_expression* must return a repeatable value. For example, you cannot specify the SYSDATE or USER function or the ROWNUM pseudocolumn.

> **See Also:**
>
> CREATE FUNCTION and *Oracle Database PL/SQL Language Reference*

ASC | DESC

Use ASC or DESC to indicate whether the index should be created in ascending or descending order. Indexes on character data are created in ascending or descending order of the character values in the database character set.

Oracle Database treats descending indexes as if they were function-based indexes. As with other function-based indexes, the database does not use descending indexes until you first analyze the index and the table on which the index is defined. See the *column_expression* clause of this statement.

Ascending unique indexes allow multiple NULL values. However, in descending unique indexes, multiple NULL values are treated as duplicate values and therefore are not permitted.

Restriction on Ascending and Descending Indexes

You cannot specify either of these clauses for a domain index. You cannot specify DESC for a reverse index. Oracle Database ignores DESC if *index* is bitmapped or if the COMPATIBLE initialization parameter is set to a value less than 8.1.0.

index_attributes

Specify the optional index attributes.

physical_attributes_clause

Use the *physical_attributes_clause* to establish values for physical and storage characteristics for the index.

If you omit this clause, then Oracle Database sets PCTFREE to 10 and INITRANS to 2.

Restriction on Index Physical Attributes

You cannot specify the PCTUSED parameter for an index.

> **See Also:**
>
> *physical_attributes_clause* and storage_clause for a complete description of these clauses

TABLESPACE

For *tablespace*, specify the name of the tablespace to hold the index, index partition, or index subpartition. If you omit this clause, then Oracle Database creates the index in the default tablespace of the owner of the schema containing the index.

For a local index, you can specify the keyword DEFAULT in place of *tablespace*. New partitions or subpartitions added to the local index will be created in the same tablespace(s) as the corresponding partitions or subpartitions of the underlying table.

index_compression

The *index_compression* clauses let you enable or disable index compression for the index. Specify the COMPRESS clause of *prefix_compression* to enable prefix compression for the index, specify the COMPRESS ADVANCED clause of *advanced_index_compression* to enable advanced index compression for the index, or specify the NOCOMPRESS clause of either *prefix_compression* or *advanced_index_compression* to disable compression for the index. The default is NOCOMPRESS.

If you want to use compression for a partitioned index, then you must create the index with compression enabled at the index level. You can subsequently enable and disable the compression setting for individual partitions of such a partitioned index. You can also enable and disable compression when rebuilding individual partitions. You can modify an existing nonpartitioned index to enable or disable compression only when rebuilding the index.

prefix_compression

Specify COMPRESS to enable **prefix compression**, also known as key compression, which eliminates repeated occurrence of key column values. Use *integer* to specify the prefix length (number of prefix columns to compress). You can specify prefix compression for indexes that are nonunique or unique indexes of at least two columns.

- For unique indexes, the range of valid prefix length values is from 1 to the number of key columns minus 1. The default prefix length is the number of key columns minus 1.
- For nonunique indexes, the range of valid prefix length values is from 1 to the number of key columns. The default prefix length is the number of key columns.

advanced_index_compression

Specify this clause to enable **advanced index compression**. Advanced index compression improves compression ratios significantly while still providing efficient access to indexes. Therefore, advanced index compression works well on all supported indexes, including those indexes that are not good candidates for prefix compression.

- COMPRESS ADVANCED LOW - This level compresses the index less than the HIGH level, but provides faster access to the index. You can specify this clause for indexes that are nonunique or unique indexes of at least two columns. Before enabling COMPRESS ADVANCED LOW, the database must be at 12.1.0 or higher compatibility level.
- COMPRESS ADVANCED HIGH - This level compresses the index more than the LOW level, but provides slower access to the index. You can specify this clause for indexes that are

nonunique or unique indexes of one or more columns. Before enabling `COMPRESS ADVANCED HIGH`, the database must be at `12.2.0` or higher compatibility level.

If you omit the `LOW` and `HIGH` keywords, then the default is `HIGH`.

Restrictions on Index Compression

The following restrictions apply to index compression:

- You cannot specify prefix compression or advanced index compression for a bitmap index.
- You cannot specify advanced index compression for index-organized tables.

> **See Also:**
>
> - DB_INDEX_COMPRESSION_INHERITANCE for more on how index creation inherits compression attributes
> - *Oracle Database Administrator's Guide* for more information on prefix compression and advanced index compression
> - "Compressing an Index: Example"

partial_index_clause

You can specify this clause only when creating an index on a partitioned table. Specify `INDEXING FULL` to create a **full index**. Specify `INDEXING PARTIAL` to create a **partial index**. The default is `INDEXING FULL`.

A full index includes all partitions in the underlying table, regardless of their indexing properties. A partial index includes only partitions in the underlying table with an indexing property of `ON`.

If a partial index is a local partitioned index, then index partitions that correspond with table partitions with an indexing property of `ON` are marked `USABLE`. Index partitions that correspond with table partitions with an indexing property of `OFF` are marked `UNUSABLE`.

If the underlying table is a composite-partitioned table, then the preceding conditions for index partitions and table partitions apply instead to index subpartitions and table subpartitions.

Restrictions on Partial Indexes

Partial indexes are subject to the following restrictions:

- The underlying table of a partial index cannot be a nonpartitioned table.
- Unique indexes cannot be partial indexes. This applies to indexes created with the `CREATE UNIQUE INDEX` statement and indexes that are implicitly created when you specify a unique constraint on one or more columns.

> **See Also:**
>
> `CREATE TABLE` *indexing_clause* for information on the indexing property

SORT | NOSORT

By default, Oracle Database sorts indexes in ascending order when it creates the index. You can specify `NOSORT` to indicate to the database that the rows are already stored in the database in ascending order, so that Oracle Database does not have to sort the rows when creating the index. If the rows of the indexed column or columns are not stored in ascending order, then the database returns an error. For greatest savings of sort time and space, use this clause immediately after the initial load of rows into a table. If you specify neither of these keywords, then `SORT` is the default.

Restrictions on NOSORT

This parameter is subject to the following restrictions:

- You cannot specify `REVERSE` with this clause.
- You cannot use this clause to create a cluster index partitioned or bitmap index.
- You cannot specify this clause for a secondary index on an index-organized table.

REVERSE

Specify `REVERSE` to store the bytes of the index block in reverse order, excluding the rowid.

Restrictions on Reverse Indexes

Reverse indexes are subject to the following restrictions:

- You cannot specify `NOSORT` with this clause.
- You cannot reverse a bitmap index or an index on an index-organized table.

VISIBLE | INVISIBLE

Use this clause to specify whether the index is visible or invisible to the optimizer. An invisible index is maintained by DML operations, but it is not be used by the optimizer during queries unless you explicitly set the parameter `OPTIMIZER_USE_INVISIBLE_INDEXES` to `TRUE` at the session or system level.

To determine whether an existing index is visible or invisible to the optimizer, you can query the `VISIBILITY` column of the `USER_`, `DBA_`, `ALL_INDEXES` data dictionary views.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information on this feature

logging_clause

Specify whether the creation of the index will be logged (`LOGGING`) or not logged (`NOLOGGING`) in the redo log file. This setting also determines whether subsequent Direct Loader (SQL*Loader) and direct-path `INSERT` operations against the index are logged or not logged. `LOGGING` is the default.

If *`index`* is nonpartitioned, then this clause specifies the logging attribute of the index.

If *`index`* is partitioned, then this clause determines:

- The default value of all partitions specified in the `CREATE` statement, unless you specify the *`logging_clause`* in the `PARTITION` description clause
- The default value for the segments associated with the index partitions
- The default value for local index partitions or subpartitions added implicitly during subsequent `ALTER TABLE ... ADD PARTITION` operations

The logging attribute of the index is independent of that of its base table.

If you omit this clause, then the logging attribute is that of the tablespace in which it resides.

> **See Also:**
>
> - *logging_clause* for a full description of this clause
> - *Oracle Database VLDB and Partitioning Guide* for more information about logging and parallel DML
> - "Creating an Index in NOLOGGING Mode: Example"

ONLINE

Specify `ONLINE` to indicate that DML operations on the table will be allowed during creation of the index.

Restrictions on Online Index Building

Online index building is subject to the following restrictions:

- Parallel DML is not supported during online index building. If you specify `ONLINE` and then issue parallel DML statements, then Oracle Database returns an error.
- You can specify `ONLINE` for a bitmap index or a cluster index as long as you set `COMPATIBLE` to 10 or higher.
- You cannot specify `ONLINE` for a conventional index on a `UROWID` column.
- For a nonunique secondary index on an index-organized table, the number of index key columns plus the number of primary key columns that are included in the logical rowid in the index-organized table cannot exceed 32. The logical rowid excludes columns that are part of the index key.

> **See Also:**
>
> *Oracle Database Concepts* for a description of online index building and rebuilding

parallel_clause

Specify the *`parallel_clause`* if you want creation of the index to be parallelized.

For complete information on this clause, refer to *parallel_clause* in the documentation on `CREATE TABLE`.

Index Partitioning Clauses

Use the *global_partitioned_index* clause and the *local_partitioned_index* clauses to partition *index*.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to *Oracle Database VLDB and Partitioning Guide* for a discussion of these restrictions.

> **See Also:**
>
> "Partitioned Index Examples"

annotations_clause

For the full semantics of the annotations clause see *annotations_clause*.

global_partitioned_index

The *global_partitioned_index* clause lets you specify that the partitioning of the index is user defined and is not equipartitioned with the underlying table. By default, nonpartitioned indexes are global indexes.

You can partition a global index by range or by hash. In both cases, you can specify up to 32 columns as partitioning key columns. The partitioning column list must specify a left prefix of the index column list. If the index is defined on columns `a`, `b`, and `c`, then for the columns you can specify `(a, b, c)`, or `(a, b)`, or `(a, c)`, but you cannot specify `(b, c)` or `(c)` or `(b, a)`. If you specify a partition name, then it must conform to the rules for naming schema objects and their parts as described in "Database Object Naming Rules ". If you omit the partition names, then Oracle Database assigns names of the form `SYS_Pn`.

GLOBAL PARTITION BY RANGE

Use this clause to create a range-partitioned global index. Oracle Database will partition the global index on the ranges of values from the table columns you specify in the column list.

> **See Also:**
>
> "Creating a Range-Partitioned Global Index: Example"

GLOBAL PARTITION BY HASH

Use this clause to create a hash-partitioned global index. Oracle Database assigns rows to the partitions using a hash function on values in the partitioning key columns.

> **See Also:**
>
> The `CREATE TABLE` clause *hash_partitions* for information on the two methods of hash partitioning and "Creating a Hash-Partitioned Global Index: Example"

Restrictions on Global Partitioned Indexes

Global partitioned indexes are subject to the following restrictions:

- The partitioning key column list cannot contain the `ROWID` pseudocolumn or a column of type `ROWID`.
- The only property you can specify for hash partitions is tablespace storage. Therefore, you cannot specify LOB or varray storage clauses in the *partitioning_storage_clause* of *individual_hash_partitions*.
- You cannot specify the `OVERFLOW` clause of *hash_partitions_by_quantity*, as that clause is valid only for index-organized table partitions.
- In the *partitioning_storage_clause*, you cannot specify *table_compression* or the *inmemory_clause*, but you can specify *index_compression*.

> **Note:**
>
> If your enterprise has or will have databases using different character sets, then use caution when partitioning on character columns. The sort sequence of characters is not identical in all character sets.

> **See Also:**
>
> *Oracle Database Globalization Support Guide* for more information on character set support

index_partitioning_clause

Use this clause to describe the individual index partitions. The number of repetitions of this clause determines the number of partitions. If you omit *partition*, then Oracle Database generates a name with the form `SYS_Pn`.

For `VALUES LESS THAN` (*value_list*), specify the noninclusive upper bound for the current partition in a global index. The value list is a comma-delimited, ordered list of literal values corresponding to the column list in the *global_partitioned_index* clause. Always specify `MAXVALUE` as the value of the last partition.

> **Note:**
>
> If the index is partitioned on a `DATE` column, and if the date format does not specify the first two digits of the year, then you must use the `TO_DATE` function with a 4-character format mask for the year. The date format is determined implicitly by `NLS_TERRITORY` or explicitly by `NLS_DATE_FORMAT`. Refer to *Oracle Database Globalization Support Guide* for more information on these initialization parameters.

> **See Also:**
>
> "Range Partitioning Example"

local_partitioned_index

The *local_partitioned_index* clauses let you specify that the index is partitioned on the same columns, with the same number of partitions and the same partition bounds as *table*. For composite-partitioned tables, this clause lets you specify that the index is subpartitioned on the same columns, with the same number of subpartitions and the same subpartition bounds as *table*. Oracle Database automatically maintains local index partitioning as the underlying table is repartitioned.

If you specify only the keyword LOCAL and do not specify a subclause, then Oracle Database creates each index partition in the same tablespace as its corresponding table partition and assigns it the same name as its corresponding table partition. If *table* is a composite-partitioned table, then Oracle Database creates each index subpartition in the same tablespace as its corresponding table subpartition and assigns it the same name as its corresponding table subpartition.

If you specify a partition name, then it must conform to the rules for naming schema objects and their parts as described in "Database Object Naming Rules ". If you omit a partition name, then Oracle Database generates a name that is consistent with the corresponding table partition. If the name conflicts with an existing index partition name, then the database uses the form SYS_Pn.

on_range_partitioned_table

This clause lets you specify the names and attributes of index partitions on a range-partitioned table. If you specify this clause, then the number of PARTITION clauses must be equal to the number of table partitions, and in the same order.

You cannot specify prefix compression for an index partition unless you have specified prefix compression for the index.

For more information on the USABLE and UNUSABLE clauses, refer to USABLE | UNUSABLE.

on_list_partitioned_table

The *on_list_partitioned_table* clause is identical to on_range_partitioned_table.

on_hash_partitioned_table

This clause lets you specify names and tablespace storage for index partitions on a hash-partitioned table.

If you specify any PARTITION clauses, then the number of these clauses must be equal to the number of table partitions. You can optionally specify tablespace storage for one or more individual partitions. If you do not specify tablespace storage either here or in the STORE IN clause, then the database stores each index partition in the same tablespace as the corresponding table partition.

The STORE IN clause lets you specify one or more tablespaces across which Oracle Database will distribute all the index hash partitions. The number of tablespaces need not equal the number of index partitions. If the number of index partitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

For more information on the USABLE and UNUSABLE clauses, refer to USABLE | UNUSABLE.

on_comp_partitioned_table

This clause lets you specify the name and attributes of index partitions on a composite-partitioned table.

The STORE IN clause is valid only for range-hash or list-hash composite-partitioned tables. It lets you specify one or more default tablespaces across which Oracle Database will distribute all index hash subpartitions for all partitions. You can override this storage by specifying different default tablespace storage for the subpartitions of an individual partition in the second STORE IN clause in the *index_subpartition_clause*.

For range-range, range-list, and list-list composite-partitioned tables, you can specify default attributes for the range or list subpartitions in the PARTITION clause. You can override this storage by specifying different attributes for the range or list subpartitions of an individual partition in the SUBPARTITION clause of the *index_subpartition_clause*.

You cannot specify prefix compression for an index partition unless you have specified prefix compression for the index.

For more information on the USABLE and UNUSABLE clauses, refer to USABLE | UNUSABLE.

index_subpartition_clause

This clause lets you specify names and tablespace storage for index subpartitions in a composite-partitioned table.

The STORE IN clause is valid only for hash subpartitions of a range-hash and list-hash composite-partitioned table. It lets you specify one or more tablespaces across which Oracle Database will distribute all the index hash subpartitions. The SUBPARTITION clause is valid for all subpartition types.

If you specify any SUBPARTITION clauses, then the number of those clauses must be equal to the number of table subpartitions. If you specify a subpartition name, then it must conform to the rules for naming schema objects and their parts as described in "Database Object Naming Rules ". If you omit *subpartition*, then the database generates a name that is consistent with the corresponding table subpartition. If the name conflicts with an existing index subpartition name, then the database uses the form SYS_SUBP*n*.

The number of tablespaces need not equal the number of index subpartitions. If the number of index subpartitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

If you do not specify tablespace storage for subpartitions either in the *on_comp_partitioned_table* clause or in the *index_subpartition_clause*, then Oracle Database uses the tablespace specified for *index*. If you also do not specify tablespace storage for *index*, then the database stores the subpartition in the same tablespace as the corresponding table subpartition.

For more information on the USABLE and UNUSABLE clauses, refer to CREATE INDEX ... USABLE | UNUSABLE.

domain_index_clause

Use the *domain_index_clause* to indicate that *index* is a domain index, which is an instance of an application-specific index of type *indextype*.

Creating a domain index requires a number of preceding operations. You must first create an implementation type for an indextype. You must also create a functional implementation and

then create an operator that uses the function. Next you create an indextype, which associates the implementation type with the operator. Finally, you create the domain index using this clause. Refer to Extended Examples, which contains an example of creating a simple domain index, including all of these operations.

index_expr

In the *index_expr* (in *table_index_clause*), specify the table columns or object attributes on which the index is defined. You can define multiple domain indexes on a single column only if the underlying indextypes are different and the indextypes support a disjoint set of user-defined operators.

Restrictions on Domain Indexes

Domain indexes are subject to the following restrictions:

- The *index_expr* (in *table_index_clause*) can specify only a single column, and the column cannot be of data type REF, varray, nested table, LONG, or LONG RAW.
- You cannot create a bitmap or unique domain index.
- You cannot create a domain index on a temporary table.
- You can create local domain indexes on only range-, list-, hash-, and interval-partitioned tables, with one exception: You cannot create a local domain index on an automatic list-partitioned table.
- Domain indexes can be created only on table columns declared with collation BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS. See *Oracle Database Globalization Support Guide* for more information.

indextype

For *indextype*, specify the name of the indextype. This name should be a valid schema object that has already been created.

If you have installed Oracle Text, then you can use various built-in indextypes to create Oracle Text domain indexes. For more information on Oracle Text and the indexes it uses, refer to *Oracle Text Reference*.

> **See Also:**
>
> CREATE INDEXTYPE

local_domain_index_clause

Use this clause to specify that the index is a local index on a partitioned table.

- The PARTITIONS clause lets you specify names for the index partitions. The number of partitions you specify must match the number of partitions in the base table. If you omit this clause, then the database creates the partitions with system-generated names of the form SYS_P*n*.
- The PARAMETERS clause lets you specify the parameter string specific to an individual partition. If you omit this clause, then the parameter string associated with the index is also associated with the partition.

parallel_clause

Use the *parallel_clause* to parallelize creation of the domain index. For a nonpartitioned domain index, Oracle Database passes the explicit or default degree of parallelism to the ODCIIndexCreate cartridge routine, which in turn establishes parallelism for the index. For local domain indexes, this clause causes the index partitions to be created in parallel.

> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide* for complete information on the Oracle Data Cartridge Interface (ODCI) routines

PARAMETERS

In the PARAMETERS clause, specify the parameter string that is passed uninterpreted to the appropriate ODCI indextype routine. The maximum length of the parameter string is 1000 characters.

When you specify this clause at the top level of the syntax, the parameters become the default parameters for the index partitions. If you specify this clause as part of the *local_domain_index_clause*, then you override any default parameters with parameters for the individual partition.

After the domain index is created, Oracle Database invokes the appropriate ODCI routine. If the routine does not return successfully, then the domain index is marked FAILED. The only operations supported on an failed domain index are DROP INDEX and (for non-local indexes) REBUILD INDEX.

> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide* for information on the Oracle Data Cartridge Interface (ODCI) routines

XMLIndex_clause

The *XMLIndex_clause* lets you define an XMLIndex index, typically on a column contain XML data. An XMLIndex index is a type of domain index designed specifically for the domain of XML data.

XMLIndex_parameters_clause

This clause lets you specify information about the path table and about the secondary indexes corresponding to the components of XMLIndex. This clause also lets you specify information about the structured component of the index. The maximum length of the parameter string is 1000 characters.

When you specify this clause at the top level of the syntax, the parameters become the parameters of the index and the default parameters for the index partitions. If you specify this clause as part of the *local_xmlindex_clause* clause, then you override any default parameters with parameters for the individual partition.

> **See Also:**
>
> *Oracle XML DB Developer's Guide* for the syntax and semantics of the *XMLIndex_parameters_clause*, as well as detailed information about the use of XMLIndex

bitmap_join_index_clause

Use the *bitmap_join_index_clause* to define a **bitmap join index**. A bitmap join index is defined on a single table. For an index key made up of dimension table columns, it stores the fact table rowids corresponding to that key. In a data warehousing environment, the table on which the index is defined is commonly referred to as a **fact table**, and the tables with which this table is joined are commonly referred to as **dimension tables**. However, a star schema is not a requirement for creating a join index.

ON

In the ON clause, first specify the fact table, and then inside the parentheses specify the columns of the dimension tables on which the index is defined.

FROM

In the FROM clause, specify the joined tables.

WHERE

In the WHERE clause, specify the join condition.

If the underlying fact table is partitioned, then you must also specify one of the *local_partitioned_index* clauses (see *local_partitioned_index*).

Restrictions on Bitmap Join Indexes

In addition to the restrictions on bitmap indexes in general (see BITMAP), the following restrictions apply to bitmap join indexes:

- You cannot create a bitmap join index on a temporary table.
- No table may appear twice in the FROM clause.
- You cannot create a function-based join index.
- The dimension table columns must be either primary key columns or have unique constraints.
- If a dimension table has a composite primary key, then each column in the primary key must be part of the join.
- You cannot specify the *local_partitioned_index* clause unless the fact table is partitioned.
- A bitmap join index definition can only reference columns with collation BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS. For any of these collations, index keys are collated and the join condition is evaluated using the BINARY collation. See *Oracle Database Globalization Support Guide* for more information.

> **Note:**
>
> *Oracle Database Data Warehousing Guide* for information on fact and dimension tables and on using bitmap indexes in a data warehousing environment

USABLE | UNUSABLE

You can specify the `USABLE` and `UNUSABLE` keywords:

- For an index, in the `CREATE INDEX` statement
- For an index partition, in the *`on_range_partitioned_table`*, *`on_list_partitioned_table`*, *`on_hash_partitioned_table`*, and *`on_comp_partitioned_table`* clauses
- For an index subpartition, in the *`index_subpartition_clause`*

For nonpartitioned indexes, specify `UNUSABLE` to create an index in an unusable state. An unusable index must be rebuilt, or dropped and re-created, before it can be used. Specify `USABLE` to create an index in a usable state. `USABLE` is the default.

For partitioned indexes, specify `USABLE` or `UNUSABLE` as follows:

- If you specify `UNUSABLE` for the index, then all index partitions are marked `UNUSABLE`.
- If you specify `USABLE` for the index, then all index partitions are marked `USABLE`.
- If you do not specify `USABLE` or `UNUSABLE` for the index, then all index partitions are marked `USABLE`. The exception is a local partial index. If you specify the `LOCAL` and `INDEXING PARTIAL` clauses, and do not specify `USABLE` or `UNUSABLE`, then each index partition is marked `USABLE` if the indexing property of its corresponding table partition is `ON`, or `UNUSABLE` if the indexing property of its corresponding table partition is `OFF`.

You can override the preceding conditions by specifying `USABLE` or `UNUSABLE` for a specific index partition.

If the underlying table is a composite-partitioned table, then the preceding conditions for index partitions and table partitions apply instead to index subpartitions and table subpartitions.

After you create a partitioned index, you can choose to rebuild specific index partitions or subpartitions to make them `USABLE`. Doing so can be useful if you want to maintain indexes only on some index partitions or subpartitions—for example, if you want to enable index access for new partitions but not for old partitions.

When an index, or some partitions or subpartitions of an index, are created `UNUSABLE`, no segment is allocated for the unusable object. The unusable index or index partition consumes no space in the database.

If an index, or some partitions or subpartitions of the index, are marked `UNUSABLE`, then the index will be considered as an access path by the optimizer only under the following circumstances: the optimizer must know at compile time which partitions are to be accessed, and all of those partitions to be accessed must be marked `USABLE`. Therefore, the query cannot contain any bind variables.

Restrictions on USABLE | UNUSABLE

The following restrictions apply when marking an index `USABLE` or `UNUSABLE`:

- You cannot specify this clause for an index on a temporary table.

- Unusable indexes or index partitions will still have a segment under the following conditions:
  - The index (or index partition) is owned by `SYS`, `SYSTEM`, `PUBLIC`, `OUTLN`, or `XDB`
  - The index (or index partition) is stored in dictionary-managed tablespaces
  - The global partitioned or nonpartitioned index on a partitioned table becomes unusable due to a partition maintenance operation

{ DEFERRED | IMMEDIATE } INVALIDATION

This clause lets you control when the database invalidates dependent cursors while creating the index. It has the same semantics here as for the `ALTER INDEX` statement. Refer to { DEFERRED | IMMEDIATE } INVALIDATION in the documentation on `ALTER INDEX` for the full semantics of this clause.

Examples

General Index Examples

Creating an Index: Example

The following statement shows how the sample index `ord_customer_ix` on the `customer_id` column of the sample table `oe.orders` was created:

```
CREATE INDEX ord_customer_ix
   ON orders (customer_id);
```

Compressing an Index: Example

To create the `ord_customer_ix_demo` index with the `COMPRESS` clause, you might issue the following statement:

```
CREATE INDEX ord_customer_ix_demo
   ON orders (customer_id, sales_rep_id)
   COMPRESS 1;
```

The index will compress repeated occurrences of `customer_id` column values.

Creating an Index in NOLOGGING Mode: Example

If the sample table `orders` had been created using a fast parallel load (so all rows were already sorted), then you could issue the following statement to quickly create an index.

```
/* Unless you first sort the table oe.orders, this example fails
   because you cannot specify NOSORT unless the base table is
   already sorted.
*/
CREATE INDEX ord_customer_ix_demo
   ON orders (order_mode)
   NOSORT
   NOLOGGING;
```

Creating a Cluster Index: Example

To create an index for the `personnel` cluster, which was created in "Creating a Cluster: Example", issue the following statement:

```
CREATE INDEX idx_personnel ON CLUSTER personnel;
```

No index columns are specified, because cluster indexes are automatically built on all the columns of the cluster key. For cluster indexes, all rows are indexed.

Creating an Index on an XMLType Table: Example

The following example creates an index on the area element of the `xwarehouses` table (created in "XMLType Table Examples"):

```
CREATE INDEX area_index ON xwarehouses e
   (EXTRACTVALUE(VALUE(e),'/Warehouse/Area'));
```

Such an index would greatly improve the performance of queries that select from the table based on, for example, the square footage of a warehouse, as shown in this statement:

```
SELECT e.getClobVal() AS warehouse
   FROM xwarehouses e
   WHERE EXISTSNODE(VALUE(e),'/Warehouse[Area>50000]') = 1;
```

> **See Also:**
>
> EXISTSNODE and VALUE

Function-Based Index Examples

The following examples show how to create and use function-based indexes.

Creating a Function-Based Index: Example

The following statement creates a function-based index on the `employees` table based on an uppercase evaluation of the `last_name` column:

```
CREATE INDEX upper_ix ON employees (UPPER(last_name));
```

See the "Prerequisites " for the privileges and parameter settings required when creating function-based indexes.

To increase the likelihood that Oracle Database will use the index rather than performing a full table scan, be sure that the value returned by the function is not null in subsequent queries. For example, this statement will use the index, unless some other condition exists that prevents the optimizer from doing so:

```
SELECT first_name, last_name
   FROM employees WHERE UPPER(last_name) IS NOT NULL
   ORDER BY UPPER(last_name);
```

Without the `WHERE` clause, Oracle Database may perform a full table scan.

In the next statements showing index creation and subsequent query, Oracle Database will use index `income_ix` even though the columns are in reverse order in the query:

```
CREATE INDEX income_ix
   ON employees(salary + (salary*commission_pct));

SELECT first_name||' '||last_name "Name"
   FROM employees
   WHERE (salary*commission_pct) + salary > 15000
   ORDER BY employee_id;
```

Creating a Function-Based Index on a LOB Column: Example

The following statement uses the `text_length` function to create a function-based index on a LOB column in the sample `pm` schema. See *Oracle Database PL/SQL Language Reference* for

the example that creates this function. The example selects rows from the sample table `print_media` where that `CLOB` column has fewer than 1000 characters.

```
CREATE INDEX src_idx ON print_media(text_length(ad_sourcetext));

SELECT product_id FROM print_media
   WHERE text_length(ad_sourcetext) < 1000
   ORDER BY product_id;

PRODUCT_ID
----------
      2056
      2268
      3060
      3106
```

Creating a Function-based Index on a Type Method: Example

This example entails an object type `rectangle` containing two number attributes: `length` and `width`. The `area()` method computes the area of the rectangle.

```
CREATE TYPE rectangle AS OBJECT
( length   NUMBER,
  width    NUMBER,
  MEMBER FUNCTION area RETURN NUMBER DETERMINISTIC
);

CREATE OR REPLACE TYPE BODY rectangle AS
  MEMBER FUNCTION area RETURN NUMBER IS
  BEGIN
   RETURN (length*width);
  END;
END;
```

Now, if you create a table `rect_tab` of type `rectangle`, you can create a function-based index on the `area()` method as follows:

```
CREATE TABLE rect_tab OF rectangle;
CREATE INDEX area_idx ON rect_tab x (x.area());
```

You can use this index efficiently to evaluate a query of the form:

```
SELECT * FROM rect_tab x WHERE x.area() > 100;
```

Using a Function-based Index to Define Conditional Uniqueness: Example

The following statement creates a unique function-based index on the `oe.orders` table that prevents a customer from taking advantage of promotion ID 2 ("blowout sale") more than once:

```
CREATE UNIQUE INDEX promo_ix ON orders
   (CASE WHEN promotion_id =2 THEN customer_id ELSE NULL END,
    CASE WHEN promotion_id = 2 THEN promotion_id ELSE NULL END);

INSERT INTO orders (order_id, order_date, customer_id, order_total, promotion_id)
   VALUES (2459, systimestamp, 106, 251, 2);
1 row created.

INSERT INTO orders (order_id, order_date, customer_id, order_total, promotion_id)
   VALUES (2460, systimestamp+1, 106, 110, 2);
insert into orders (order_id, order_date, customer_id, order_total, promotion_id)
*
ERROR at line 1:
ORA-00001: unique constraint (OE.PROMO_IX) violated
```

The objective is to remove from the index any rows where the promotion_id is not equal to 2. Oracle Database does not store in the index any rows where all the keys are NULL. Therefore, in this example, both customer_id and promotion_id are mapped to NULL unless promotion_id is equal to 2. The result is that the index constraint is violated only if promotion_id is equal to 2 for two rows with the same customer_id value.

Partitioned Index Examples

Creating a Range-Partitioned Global Index: Example

The following statement creates a global prefixed index cost_ix on the sample table sh.sales with three partitions that divide the range of costs into three groups:

```
CREATE INDEX cost_ix ON sales (amount_sold)
   GLOBAL PARTITION BY RANGE (amount_sold)
      (PARTITION p1 VALUES LESS THAN (1000),
       PARTITION p2 VALUES LESS THAN (2500),
       PARTITION p3 VALUES LESS THAN (MAXVALUE));
```

Creating a Hash-Partitioned Global Index: Example

The following statement creates a hash-partitioned global index cust_last_name_ix on the sample table sh.customers with four partitions:

```
CREATE INDEX cust_last_name_ix ON customers (cust_last_name)
  GLOBAL PARTITION BY HASH (cust_last_name)
  PARTITIONS 4;
```

Creating an Index on a Hash-Partitioned Table: Example

The following statement creates a local index on the category_id column of the hash_products partitioned table (which was created in "Hash Partitioning Example"). The STORE IN clause immediately following LOCAL indicates that hash_products is hash partitioned. Oracle Database will distribute the hash partitions between the tbs1 and tbs2 tablespaces:

```
CREATE INDEX prod_idx ON hash_products(category_id) LOCAL
   STORE IN (tbs_01, tbs_02);
```

The creator of the index must have quota on the tablespaces specified. See CREATE TABLESPACE for examples that create tablespaces tbs_01 and tbs_02.

Creating an Index on a Composite-Partitioned Table: Example

The following statement creates a local index on the composite_sales table, which was created in "Composite-Partitioned Table Examples". The STORAGE clause specifies default storage attributes for the index. However, this default is overridden for the five subpartitions of partitions q3_2000 and q4_2000, because separate TABLESPACE storage is specified.

The creator of the index must have quota on the tablespaces specified. See CREATE TABLESPACE for examples that create tablespaces tbs_02 and tbs_03.

```
CREATE INDEX sales_ix ON composite_sales(time_id, prod_id)
   STORAGE (INITIAL 1M)
   LOCAL
   (PARTITION q1_1998,
    PARTITION q2_1998,
    PARTITION q3_1998,
    PARTITION q4_1998,
    PARTITION q1_1999,
    PARTITION q2_1999,
    PARTITION q3_1999,
```

```
    PARTITION q4_1999,
    PARTITION q1_2000,
    PARTITION q2_2000
      (SUBPARTITION pq2001, SUBPARTITION pq2002,
       SUBPARTITION pq2003, SUBPARTITION pq2004,
       SUBPARTITION pq2005, SUBPARTITION pq2006,
       SUBPARTITION pq2007, SUBPARTITION pq2008),
    PARTITION q3_2000
      (SUBPARTITION c1 TABLESPACE tbs_02,
       SUBPARTITION c2 TABLESPACE tbs_02,
       SUBPARTITION c3 TABLESPACE tbs_02,
       SUBPARTITION c4 TABLESPACE tbs_02,
       SUBPARTITION c5 TABLESPACE tbs_02),
    PARTITION q4_2000
      (SUBPARTITION pq4001 TABLESPACE tbs_03,
       SUBPARTITION pq4002 TABLESPACE tbs_03,
       SUBPARTITION pq4003 TABLESPACE tbs_03,
       SUBPARTITION pq4004 TABLESPACE tbs_03)
);
```

Bitmap Index Examples

The following creates a bitmap index on the table `oe.hash_products`, which was created in "Hash Partitioning Example":

```
CREATE BITMAP INDEX product_bm_ix
   ON hash_products(list_price)
   LOCAL(PARTITION ix_p1 TABLESPACE tbs_01,
         PARTITION ix_p2,
         PARTITION ix_p3 TABLESPACE tbs_02,
         PARTITION ix_p4 TABLESPACE tbs_03)
   TABLESPACE tbs_04;
```

Because `hash_products` is a partitioned table, the bitmap join index must be locally partitioned. In this example, the user must have quota on tablespaces specified. See CREATE TABLESPACE for examples that create tablespaces `tbs_01`, `tbs_02`, `tbs_03`, and `tbs_04`.

The next series of statements shows how one might create a bitmap join index on a fact table using a join with a dimension table.

```
CREATE TABLE hash_products
    ( product_id          NUMBER(6)
    , product_name        VARCHAR2(50)
    , product_description VARCHAR2(2000)
    , category_id         NUMBER(2)
    , weight_class        NUMBER(1)
    , warranty_period     INTERVAL YEAR TO MONTH
    , supplier_id         NUMBER(6)
    , product_status      VARCHAR2(20)
    , list_price          NUMBER(8,2)
    , min_price           NUMBER(8,2)
    , catalog_url         VARCHAR2(50)
    , CONSTRAINT          pk_product_id PRIMARY KEY (product_id)
    , CONSTRAINT          product_status_lov_demo
                          CHECK (product_status in ('orderable'
                                                    ,'planned'
                                                    ,'under development'
                                                    ,'obsolete')
 ) )
 PARTITION BY HASH (product_id)
 PARTITIONS 5
 STORE IN (example);
```

```
CREATE TABLE sales_quota
    ( product_id          NUMBER(6)
    , customer_name       VARCHAR2(50)
    , order_qty           NUMBER(6)
  ,CONSTRAINT u_product_id UNIQUE(product_id)
 );

CREATE BITMAP INDEX product_bm_ix
   ON hash_products(list_price)
   FROM hash_products h, sales_quota s
   WHERE h.product_id = s.product_id
   LOCAL(PARTITION ix_p1 TABLESPACE example,
         PARTITION ix_p2,
         PARTITION ix_p3 TABLESPACE example,
         PARTITION ix_p4,
         PARTITION ix_p5 TABLESPACE example)
   TABLESPACE example;
```

Indexes on Nested Tables: Example

The sample table `pm.print_media` contains a nested table column `ad_textdocs_ntab`, which is stored in storage table `textdocs_nestedtab`. The following example creates a unique index on storage table `textdocs_nestedtab`:

```
CREATE UNIQUE INDEX nested_tab_ix
      ON textdocs_nestedtab(NESTED_TABLE_ID, document_typ);
```

Including pseudocolumn `NESTED_TABLE_ID` ensures distinct rows in nested table column `ad_textdocs_ntab`.

Indexing on Substitutable Columns: Examples

You can build an index on attributes of the declared type of a substitutable column. In addition, you can reference the subtype attributes by using the appropriate `TREAT` function. The following example uses the table `books`, which is created in "Substitutable Table and Column Examples". The statement creates an index on the `salary` attribute of all employee authors in the `books` table:

```
CREATE INDEX salary_i
   ON books (TREAT(author AS employee_t).salary);
```

The target type in the argument of the `TREAT` function must be the type that added the attribute being referenced. In the example, the target of `TREAT` is `employee_t`, which is the type that added the `salary` attribute.

If this condition is not satisfied, then Oracle Database interprets the `TREAT` function as any functional expression and creates the index as a function-based index. For example, the following statement creates a function-based index on the `salary` attribute of part-time employees, assigning nulls to instances of all other types in the type hierarchy.

```
CREATE INDEX salary_func_i ON persons p
   (TREAT(VALUE(p) AS part_time_emp_t).salary);
```

You can also build an index on the type-discriminant column underlying a substitutable column by using the `SYS_TYPEID` function.

> **Note:**
>
> Oracle Database uses the type-discriminant column to evaluate queries that involve the `IS OF type` condition. The cardinality of the typeid column is normally low, so Oracle recommends that you build a bitmap index in this situation.

The following statement creates a bitmap index on the typeid of the author column of the books table:

```
CREATE BITMAP INDEX typeid_i ON books (SYS_TYPEID(author));
```

> **See Also:**
>
> - *Oracle Database PL/SQL Language Reference* to see the creation of the type hierarchy underlying the `books` table
> - the functions TREAT and SYS_TYPEID and the condition "IS OF *type* Condition "

CREATE INDEXTYPE

Purpose

Use the `CREATE INDEXTYPE` statement to create an **indextype**, which is an object that specifies the routines that manage a domain (application-specific) index. Indextypes reside in the same namespace as tables, views, and other schema objects. This statement binds the indextype name to an implementation type, which in turn specifies and refers to user-defined index functions and procedures that implement the indextype.

> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide* for more information on implementing indextypes

Prerequisites

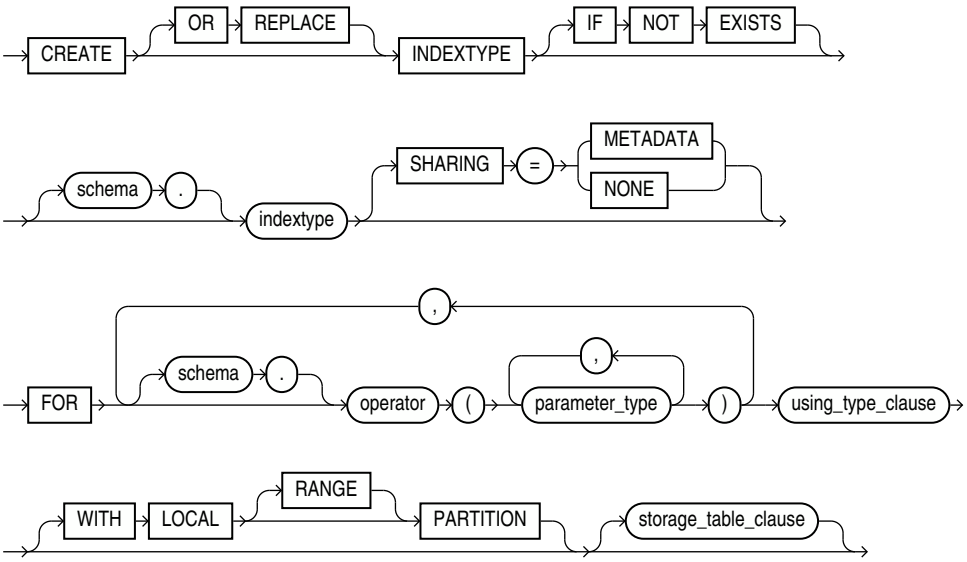
To create an indextype in your own schema, you must have the `CREATE INDEXTYPE` system privilege. To create an indextype in another schema, you must have the `CREATE ANY INDEXTYPE` system privilege. In either case, you must have the `EXECUTE` object privilege on the implementation type and the supported operators.

An indextype supports one or more operators, so before creating an indextype, you must first design the operator or operators to be supported and provide functional implementation for those operators.

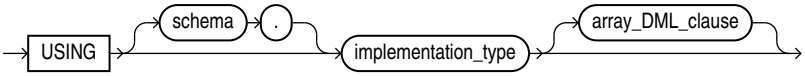
> **See Also:**
>
> CREATE OPERATOR

Syntax

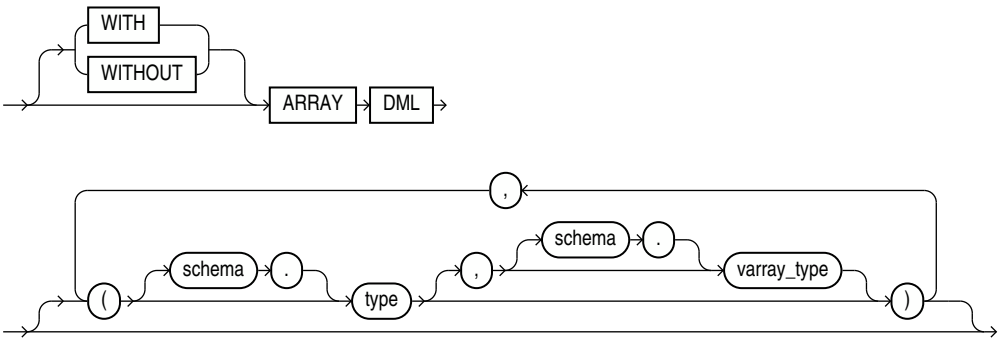
***create_indextype*::=**



***using_type_clause*::=**



***array_DML_clause*::=**



***storage_table_clause*::=**

Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the indextype if it already exists. You can use this clause to change the definition of an existing indextype without dropping, re-creating, and regranting object privileges previously granted on it.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the indextype does not exist, a new indextype is created at the end of the statement.
- If the indextype exists, this is the indextype you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

schema

Specify the name of the schema in which the indextype resides. If you omit *`schema`*, then Oracle Database creates the indextype in your own schema.

indextype

Specify the name of the indextype to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

SHARING

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- `METADATA` - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- `NONE` - The object is not shared and can only be accessed in the application root.

FOR Clause

Use the `FOR` clause to specify the list of operators supported by the indextype.

- For *schema*, specify the schema containing the operator. If you omit *schema*, then Oracle assumes the operator is in your own schema.
- For *operator*, specify the name of the operator supported by the indextype.

  All the operators listed in this clause must be valid operators.
- For *parameter_type*, list the types of parameters to the operator.

using_type_clause

The USING clause lets you specify the type that provides the implementation for the new indextype.

For *implementation_type*, specify the name of the type that implements the appropriate Oracle Data Cartridge Interface (ODCI).

- You must specify a valid type that implements the routines in the ODCI.
- The implementation type must reside in the same schema as the indextype.

> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide* for additional information on this interface

WITH LOCAL PARTITION

Use this clause to indicate that the indextype can be used to create local domain indexes on range-, list-, hash-, and interval-partitioned tables. You use this clause in combination with the *storage_table_clause* in several ways (see *storage_table_clause*).

- The recommended method is to specify WITH LOCAL PARTITION WITH SYSTEM MANAGED STORAGE TABLES. This combination uses *system-managed* storage tables, which are the preferred storage management, and lets you create local domain indexes on range-, list-, hash-, and interval-partitioned tables. In this case the RANGE keyword is optional and ignored, because it is no longer needed if you specify WITH LOCAL PARTITION WITH SYSTEM MANAGED STORAGE TABLES.
- You can specify WITH LOCAL RANGE PARTITION (including the RANGE keyword) and omit the *storage_table* clause. Local domain indexes on range-partitioned tables are supported with *user-managed* storage tables for backward compatibility. Oracle does not recommend this combination because it uses the less efficient user-managed storage tables.

If you omit this clause entirely, then you cannot subsequently use this indextype to create a local domain index on a range, list-, hash-, or interval-partitioned table.

storage_table_clause

Use this clause to specify how storage tables and partition maintenance operations for indexes built on this indextype are managed:

- Specify WITH SYSTEM MANAGED STORAGE TABLES to indicate that the storage of statistics data is to be managed by the system. The type you specify in *statistics_type* should be storing the statistics related information in tables that are maintained by the system. Also, the indextype you specify must already have been created or altered to support the WITH SYSTEM MANAGED STORAGE TABLES clause.

- Specify `WITH USER MANAGED STORAGE TABLES` to indicate that the tables that store the user-defined statistics will be managed by the user. This is the default behavior.

> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide* for more information about storage tables for domain indexes

array_DML_clause

Use this clause to let the indextype support the array interface for the `ODCIIndexInsert` method.

type* and *varray_type

If the data type of the column to be indexed is a user-defined object type, then you must specify this clause to identify the varray *`varray_type`* that Oracle should use to hold column values of *`type`*. If the indextype supports a list of types, then you can specify a corresponding list of varray types. If you omit *`schema`* for either *`type`* or *`varray_type`*, then Oracle assumes the type is in your own schema.

If the data type of the column to be indexed is a built-in system type, then any varray type specified for the indextype takes precedence over the ODCI types defined by the system.

> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide* for more information on the ODCI array interface

Examples

Creating an Indextype: Example

The following statement creates an indextype named `position_indextype` and specifies the `position_between` operator that is supported by the indextype and the `position_im` type that implements the index interface. Refer to "Using Extensible Indexing " for an extensible indexing scenario that uses this indextype:

```
CREATE INDEXTYPE position_indextype
   FOR position_between(NUMBER, NUMBER, NUMBER)
   USING position_im;
```

CREATE INMEMORY JOIN GROUP

Purpose

Use the `CREATE INMEMORY JOIN GROUP` statement to create a join group, which is an object that specifies frequently joined columns from the same table or different tables. Such columns typically contain values of compatible data types that fall in similar ranges. When you create a join group, Oracle Database stores special metadata for the columns in the global dictionary, which enables the database to optimize join queries for the columns. In order to achieve this

optimization, the table columns must be populated in the In-Memory Column Store (IM column store).

Creating a join group for tables causes the current In-Memory contents of these tables to be invalidated. Subsequent repopulation causes the In-Memory Compression Units (IMCUs) of the tables to be re-encoded with the global dictionary. Thus, Oracle recommends that you first create the join group, and then populate the tables.

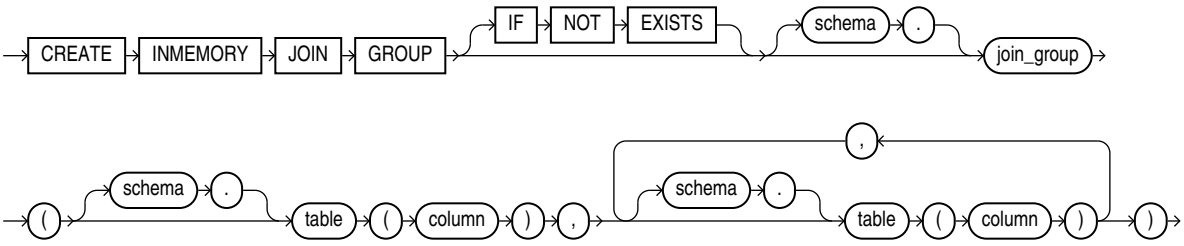
> **See Also:**
>
> - ALTER INMEMORY JOIN GROUP and DROP INMEMORY JOIN GROUP
> - *Oracle Database In-Memory Guide* for more information on join groups

Prerequisites

To create a join group in another user's schema, or to include in the join group a column in a table in another user's schema, you must have the `CREATE ANY TABLE` system privilege.

Syntax

***create_inmemory_join_group*::=**



Semantics

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the object does not exist, a new obejct is created at the end of the statement.
- If the object exists, this is the object you have at the end of the statement. A new one is not created because the older object is detected.

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

schema

Specify the schema to contain the join group. If you omit *`schema`*, then the database creates the join group in your own schema.

join_group

Specify the name of the join group to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

schema

Specify the schema of the table that contains a column to be included in the join group If you omit *schema*, then Oracle Database assumes the table is in your own schema.

table

Specify the name of the table that contains a column to be included in the join group.

column

Specify the name of a column to be included in the join group. A join group can contain columns in the same table or different tables.

Restrictions on Join Groups

The following restrictions apply to join groups:

- A join group must contain at least 1 column.
- A join group can contain at most 255 columns.
- A table column can be a member of at most one join group.
- Oracle Active Data Guard does not support join groups.

Examples

The following statement creates a join group named `prod_id1` in the `oe` schema. Both tables involved in this join group reside in the `oe` schema.

```
CREATE INMEMORY JOIN GROUP prod_id1
  (inventories(product_id), order_items(product_id));
```

The following statement creates a join group named `prod_id2` in the `oe` schema. The table `inventories` resides in the `oe` schema and the table `online_media` resides in the `pm` schema.

```
CREATE INMEMORY JOIN GROUP prod_id2
  (inventories(product_id), pm.online_media(product_id));
```

CREATE JAVA

Purpose

Use the `CREATE JAVA` statement to create a schema object containing a Java source, class, or resource.

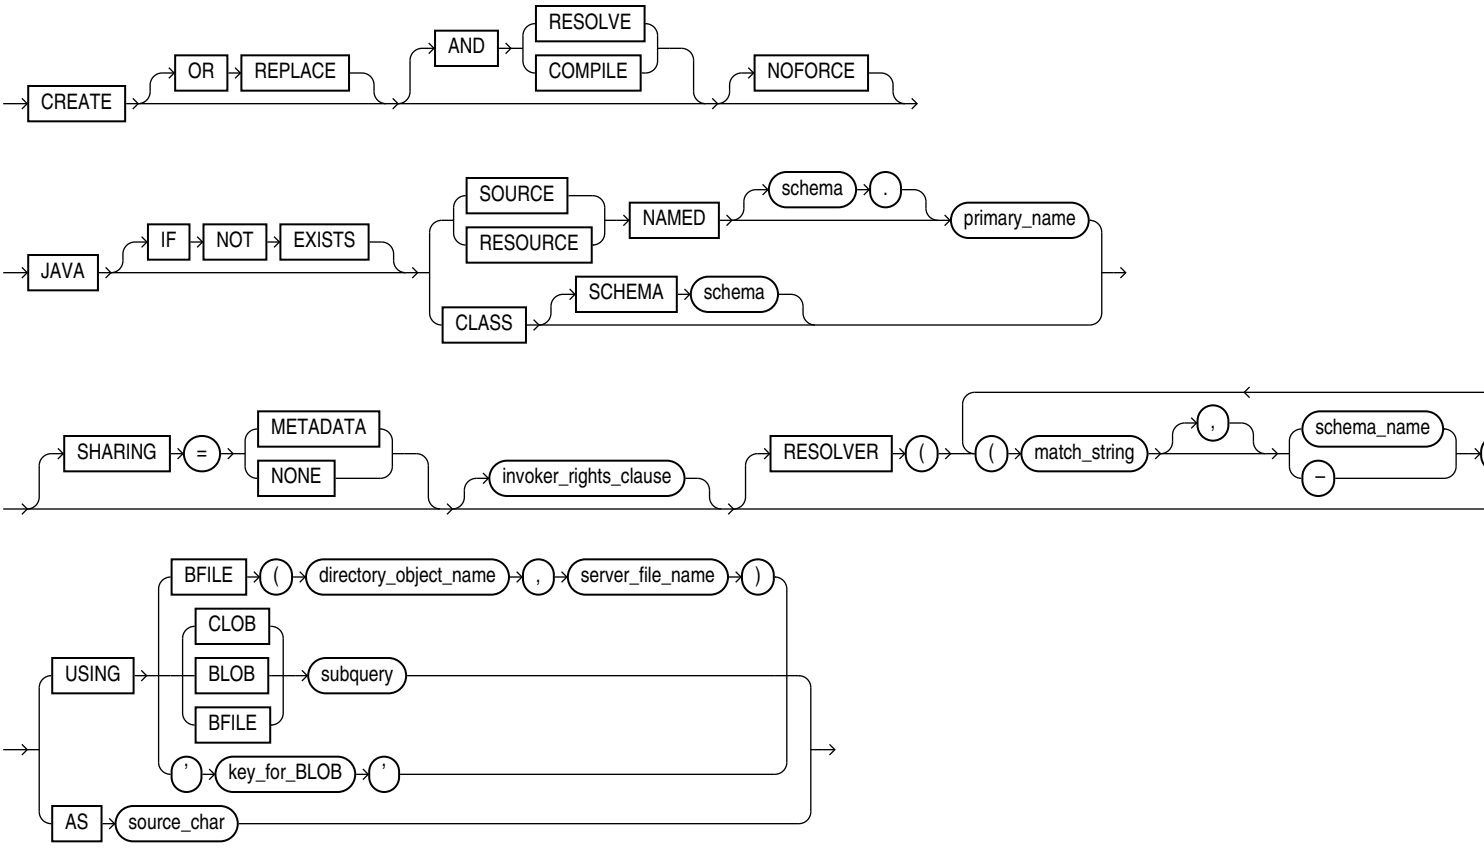
> **See Also:**
>
> - *Oracle Database Java Developer's Guide* for Java concepts and information about Java stored procedures
> - *Oracle Database JDBC Developer's Guide* for information on JDBC

Prerequisites

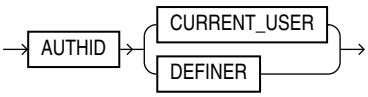
To create or replace a schema object containing a Java source, class, or resource in your own schema, you must have `CREATE PROCEDURE` system privilege. To create or replace such a schema object in another user's schema, you must have `CREATE ANY PROCEDURE` system privilege.

Syntax

***create_java*::=**



***invoker_rights_clause*::=**



Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the schema object containing the Java class, source, or resource if it already exists. Use this clause to change the definition of an existing object without dropping, re-creating, and regranting object privileges previously granted.

If you redefine a Java schema object and specify `RESOLVE` or `COMPILE`, then Oracle Database recompiles or resolves the object. Whether or not the resolution or compilation is successful, the database invalidates classes that reference the Java schema object.

Users who had previously been granted privileges on a redefined function can still access the function without being regranted the privileges.

> **See Also:**
>
> ALTER JAVA for additional information

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the object does not exist, a new object is created at the end of the statement.
- If the object exists, this is the object you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

RESOLVE | COMPILE

`RESOLVE` and `COMPILE` are synonymous keywords. They specify that Oracle Database should attempt to resolve the Java schema object that is created if this statement succeeds.

- When applied to a class, resolution of referenced names to other class schema objects occurs.
- When applied to a source, source compilation occurs.

Restriction on RESOLVE and COMPILE

You cannot specify these keywords for a Java resource.

NOFORCE

Specify `NOFORCE` to roll back the results of this `CREATE` command if you have specified either `RESOLVE` or `COMPILE` and the resolution or compilation fails. If you do not specify this option, then Oracle Database takes no action if the resolution or compilation fails, and the created schema object remains.

JAVA SOURCE Clause

Specify `JAVA SOURCE` to load a Java source file.

JAVA CLASS Clause

Specify `JAVA CLASS` to load a Java class file.

JAVA RESOURCE Clause

Specify `JAVA RESOURCE` to load a Java resource file.

NAMED Clause

The `NAMED` clause is required for a Java source or resource. The *`primary_name`* must be enclosed in double quotation marks and its length must not exceed 4000 bytes in the database character set.

- For a Java source, this clause specifies the name of the schema object in which the source code is held. A successful `CREATE JAVA SOURCE` statement will also create additional schema objects to hold each of the Java classes defined by the source.
- For a Java resource, this clause specifies the name of the schema object to hold the Java resource.

Use double quotation marks to preserve a lower- or mixed-case *`primary_name`*.

If you do not specify *`schema`*, then Oracle Database creates the object in your own schema.

Restrictions on NAMED Java Classes

The `NAMED` clause is subject to the following restrictions:

- You cannot specify `NAMED` for a Java class.
- The *`primary_name`* cannot contain a database link.

SCHEMA Clause

The `SCHEMA` clause applies only to a Java class. This optional clause specifies the schema in which the object containing the Java file will reside. If you do not specify this clause, then Oracle Database creates the object in your own schema.

SHARING

This clause applies only when creating a Java schema object in an application root. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the Java schema object is shared, specify one of the following sharing attributes:

- `METADATA` - A metadata link shares the Java schema object's metadata, but its data is unique to each container. This type of Java schema object is referred to as a **metadata-linked application common object**.
- `NONE` - The Java schema object is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the Java schema object. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

You cannot change the sharing attribute of a Java schema object after it is created.

> **See Also:**
>
> - *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
> - *Oracle Database Administrator's Guide* for complete information on creating application common objects

invoker_rights_clause

Use the *invoker_rights_clause* to indicate whether the methods of the class execute with the privileges and in the schema of the user who owns the class or with the privileges and in the schema of `CURRENT_USER`.

This clause also determines how Oracle Database resolves external names in queries, DML operations, and dynamic SQL statements in the member functions and procedures of the type.

AUTHID CURRENT_USER

`CURRENT_USER` indicates that the methods of the class execute with the privileges of `CURRENT_USER`. This clause is the default and creates an **invoker-rights class**.

This clause also specifies that external names in queries, DML operations, and dynamic SQL statements resolve in the schema of `CURRENT_USER`. External names in all other statements resolve in the schema in which the methods reside.

AUTHID DEFINER

`DEFINER` indicates that the methods of the class execute with the privileges of the owner of the schema in which the class resides, and that external names resolve in the schema where the class resides. This clause creates a **definer-rights class**.

> **See Also:**
>
> - *Oracle Database Java Developer's Guide*
> - *Oracle Database PL/SQL Language Reference* for information on how `CURRENT_USER` is determined

RESOLVER Clause

The `RESOLVER` clause lets you specify a mapping of the fully qualified Java name to a Java schema object, where:

- *match_string* is either a fully qualified Java name, a wildcard that can match such a Java name, or a wildcard that can match any name.
- *schema_name* designates a schema to be searched for the corresponding Java schema object.
- A dash (-) as an alternative to *schema_name* indicates that if *match_string* matches a valid Java name, Oracle Database can leave the name unresolved. The resolution succeeds, but the name cannot be used at run time by the class.

This mapping is stored with the definition of the schema objects created in this command for use in later resolutions (either implicit or in explicit `ALTER JAVA ... RESOLVE` statements).

USING Clause

The `USING` clause determines a sequence of character data (`CLOB` or `BFILE`) or binary data (`BLOB` or `BFILE`) for the Java class or resource. Oracle Database uses the sequence of characters to define one file for a Java class or resource, or one source file and one or more derived classes for a Java source.

BFILE Clause

Specify the directory and filename of a previously created file on the operating system (*`directory_object_name`*) and server file (*`server_file_name`*) containing the sequence. `BFILE` is usually interpreted as a character sequence by `CREATE JAVA SOURCE` and as a binary sequence by `CREATE JAVA CLASS` or `CREATE JAVA RESOURCE`.

CLOB | BLOB | BFILE *subquery*

Specify a subquery that selects a single row and column of the type specified (`CLOB`, `BLOB`, or `BFILE`). The value of the column makes up the sequence of characters.

> **Note:**
>
> In earlier releases, the `USING` clause implicitly supplied the keyword `SELECT`. This is no longer the case. However, the subquery without the keyword `SELECT` is still supported for backward compatibility.

key_for_BLOB

The *`key_for_BLOB`* clause supplies the following implicit query:

```
SELECT LOB FROM CREATE$JAVA$LOB$TABLE
   WHERE NAME = 'key_for_BLOB';
```

Restriction on the *key_for_BLOB* Clause

For you to use this case, the table `CREATE$JAVA$LOB$TABLE` must exist in the current schema and must have a column LOB of type `BLOB` and a column `NAME` of type `VARCHAR2`.

AS *source_char*

Specify a sequence of characters for a Java source.

Examples

Creating a Java Class Object: Example

The following statement creates a schema object containing a Java class using the name found in a Java binary file:

```
CREATE JAVA CLASS USING BFILE (java_dir, 'Agent.class')
/
```

This example assumes the directory object `java_dir`, which points to the operating system directory containing the Java class `Agent.class`, already exists. In this example, the name of the class determines the name of the Java class schema object.

Creating a Java Source Object: Example

The following statement creates a Java source schema object:

```
CREATE JAVA SOURCE NAMED "Welcome" AS
   public class Welcome {
      public static String welcome() {
         return "Welcome World";   } }
/
```

Creating a Java Resource Object: Example

The following statement creates a Java resource schema object named `apptext` from a `bfile`:

```
CREATE JAVA RESOURCE NAMED "appText"
   USING BFILE (java_dir, 'textBundle.dat')
/
```

CREATE JSON RELATIONAL DUALITY VIEW

Purpose

JSON-relational duality views expose data in relational tables as JSON documents. The documents are materialized on demand, not stored. Duality views give your data a conceptual and an operational duality as it is organized both relationally and hierarchically. You can base different duality views on data stored in one or more of the same tables, providing different JSON hierarchies over the same, shared data. This means that applications can access (create, query, modify) the same data as a collection of JSON documents or as a set of related tables and columns, and both approaches can be employed at the same time.

A flex column in a table underlying a JSON-relational duality view lets you add and redefine fields of the document object produced by that table. This provides a certain kind of schema flexibility to a duality view, and to the documents it supports. For more information on flex columns in a table underlying a JSON-relational duality view see JSON Data Stored in JSON-Relational Duality Views of the *JSON-Relational Duality Developer's Guide*

You define a duality view against a set of tables related by primary key (PK), foreign key (FK) or unique key constraints (UK). The following rules apply:

- The primary or unique key constraints must be declared in the database but need not be enforced (can be `RELY` constraints). Foreign key constraints are not required to be declared in the database.
- The relationships type can be 1-to-1, 1-to-N and N-to-M (using a mapping table with two FKs). The N-to-M relationship can be thought of as the combination of 1-to-N and 1-to-1 relationship
- Columns of two or more tables with 1-to-1 or N-to-1 relationships can be merged into the same JSON object via `UNNEST`. Otherwise a nested JSON object is created.
- Tables with a 1-to-N relationship create a nested JSON array.
- A duality view has only one column of type `JSON`.
- Each row in the duality view is one JSON object, which is typically a hierarchy of nested objects and arrays.
- Each application object is built from values originating from one or multiple rows from the underlying tables of that view. Typically, each table contributes to one (nested) JSON object.

> **Note:**
>
> The SQL data types allowed for a column in a table underlying a duality view are `BINARY_DOUBLE`, `BINARY_FLOAT`, `BLOB`, `BOOLEAN`, `CHAR`, `CLOB`, `DATE`, `JSON`, `INTERVAL DAY TO SECOND`, `INTERVAL YEAR TO MONTH`, `NCHAR`, `NCLOB`, `NUMBER`, `NVARCHAR2`, `VARCHAR2`, `RAW`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, and `VECTOR`. An error is raised if you specify any other column data type.

> **See Also:**
>
> *JSON-Relational Duality Developer's Guide*

Semantics

The JSON realtional duality view has only one column of data type `JSON`. The column contains the JSON object which is a representation of a application object. The column name is always `DATA`.

The duality view is read-only by default. This means that the following annotations are in effect: `NOINSERT`, `NODELETE`, `NOUPDATE`.

OR REPLACE

Specify `OR REPLACE` to re-create the view if it already exists. You can use this clause to change the definition of an existing view without dropping, re-creating, and regranting object privileges previously granted on it.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the view does not exist, a new view is created at the end of the statement.
- If the view exists, this is the view you have at the end of the statement. A new one is not created because the older one is detected.

You can have only one of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both in the same statement results in the following error:

`ORA-11541: REPLACE` and `IF NOT EXISTS` cannot coexist in the same DDL statement.

Using `IF EXISTS` with `CREATE` results in `ORA-11543`: Incorrect `IF NOT EXISTS` clause for `CREATE` statement

duality_view_replication_clause

To enable logical replication on a duality view use `CREATE JSON RELATIONAL DUALITY VIEW ENABLE LOGICAL REPLICATION`.

To disable logical replication on a duality view use `CREATE JSON RELATIONAL DUALITY VIEW DISABLE LOGICAL REPLICATION`

> **Note:**
>
> On a multi instance RAC database, you must run the `ALTER SYSTEM ENABLE RAC TWO_STAGE ROLLING UPDATES ALL` DDL, before you can enable or disable logical replication.
>
> You must run `ALTER SYSTEM ENABLE RAC TWO_STAGE ROLLING UPDATES ALL` after patching all the RAC instances.
>
> After you run `ALTER SYSTEM ENABLE RAC TWO_STAGE ROLLING UPDATES ALL` you cannot perform an online downgrade (unpatch) of your RAC database to `DBRU23.5` or lower. You must take a downtime.
>
> On a single instance database, you do not need to run `ALTER SYSTEM ENABLE RAC TWO_STAGE ROLLING UPDATES ALL`.

root_table

`root_table` refers to the top level table which the duality view is defined on. It is the only table specified in the `FROM` clause of the top level `SELECT` statement.

key_value_clause

You must have one key named `_id` that points to the column(s) that identify the JSON document, usually a primary-key column.

See Document-Identifier Field for Duality Views of the *JSON-Relational Duality Developer's Guide* .

table_tags_clause

You can mark the view as updatable using the following keyword inside a `WITH` clause:

- `WITH INSERT`
- `WITH UPDATE`

- `WITH DELETE`

You can combine keywords together without commas, for example: `WITH INSERT UPDATE`

column_tags_clause

You can mark individual columns with `WITH UPDATE` or `WITH NOUPDATE`. This supercedes table-level annotation.

Column Properties for Updatability

If the `FROM` clause is marked with such keywords, then this sets the default for all columns of the table in the `FROM` clause. You can change the default setting on an individual column. If a the `FROM` clause is specified as `WITH` (`INSERT`, `UPDATE`, `DELETE`) and a column overrides this default with `NOUPDATE`, then updates are not allowed.

Column Properties for ETAGs

Individual columns as well as a `FROM` clause can be specified to take part in the `CHECK ETAG` calculation or not. An `ETAG` is a hash value for all the columns' values in one JSON object and is used to detect changes. A column without `ETAG` can be changed without this change impacting other operations. By default all columns participate in `ETAG` calculation. Using `NOCHECK ETAG` a column can be excluded from `ETAG` calculation.

graphql_query_for DV

`graphql_query_for_DV` is a special kind of shorthand query operation definition in GraphQL.

- The *`root_query_field`* is the single top-level selection field of this shorthand query.

  For brevity, *`graphql_query_for_dv`* omits the pair of curly brackets of the top-level*`selection_set`* of a general shorthand query operation.
- *`selection_set`* syntax augments the selection set defined in the GraphQL specification with the option of optional square brackets around the selection list.
- *`selection`* in *`selection_list`* can be only *`field`* or *`fragment_spread`* .
- *`field directives`* : conform to the GraphQL specification. Only supported custom directives are allowed. @skip and @include are NOT supported.
- *`argument`* conforms to the GraphQL specification.
- *`root_query_field_name`* corresponds to the root table.
- *`name`* has the same syntax as the GraphQL specification.
- *`quoted_name`*: The field names in a GraphQL query for DV allow quoted and un-quoted names. As a convention, un-quoted field names are in lower case only. *`any_char`* is any character allowed in a quoted identifier in SQL .
- *`scalar_field_name`* corresponds to a column name of a table.
- *`object_field_name`* corresponds to a related table name. In addition you can use quoted names, and fully qualified table names with dot-concatenation.

Examples

> **See Also:**
>
> *Introduction To Car-Racing Duality Views Example* of the *JSON-Relational Duality Developer's Guide.*

Example 1: Create a Duality View of Orders

The following example is a view of an orders view object `ORDERS_OV` with the following information:

- Order information such as order status from the `Orders` table
- A `CustomerInfo` singleton descendant consisting of customer details from the `Customer` table
- An `OrderItems` array descendant consisting of a list of order items from the `OrderItems` table.
- Each order item, in turn, consists of `ItemInfo` and `ShipmentInfo` singletons from the `Products` and `Shipment` tables respectively.

```
CREATE OR REPLACE JSON RELATIONAL DUALITY VIEW ORDERS_OV AS
SELECT JSON { 'OrderId'   : ord.order_id,
              'OrderTime' : ord.order_datetime,
             'OrderStatus' : ord.order_status,
              'CustomerInfo' :
              (SELECT JSON{'CustomerId'    : cust.customer_id,
                                  'CustomerName'  : cust.full_name,
                                  'CustomerEmail' :
cust.email_address }

               FROM CUSTOMERS cust
                     WHERE cust.customer_id = ord.customer_id),
             'OrderItems' : (SELECT JSON_ARRAYAGG(
                   JSON { 'OrderItemId' : oi.line_item_id,
                                       'Quantity'    :
oi.quantity,
                                       'ProductInfo' : <subquery from product>
                                    'ShipmentInfo' : <subquery from
shipments>)

                            })
                            FROM ORDER_ITEMS oi
                            WHERE ord.order_id = oi.order_id)
}
FROM ORDERS ord;
```

Example 2: Create an Updatable View

To make the view updatable, one has to add `INSERT` or `UPDATE` or `DELETE` or any combination of these to either the `FROM` clause or individual column. The following allows to update the order, only read the customer and insert and update (not delete) order items.

```
CREATE OR REPLACE JSON RELATIONAL DUALITY VIEW ORDERS_OV AS
SELECT JSON { 'OrderId'     : ord.order_id,
              'OrderTime'.  : ord.order_datetime,
```

```
              'OrderStatus' : ord.order_status,
               'CustomerInfo' :
              (SELECT JSON{'CustomerId'    : cust.customer_id,
                           'CustomerName'  : cust.full_name,
                           'CustomerEmail' : cust.email_address WITH
NOCHECK}
                FROM CUSTOMERS c WITH CHECK
                      WHERE cust.customer_id = ord.customer_id),
               'OrderItems' : (SELECT JSON_ARRAYAGG(
                     JSON { 'OrderItemId' : oi.line_item_id,
                                          'Quantity'    : oi.quantity,
                                          'ProductInfo' : <subquery from product>
                                          'ShipmentInfo' : <subquery from
shipments>)

                               })
                               FROM ORDER_ITEMS oi WITH INSERT, UPDATE
                               WHERE ord.order_id = oi.order_id)
}
FROM ORDERS ord WITH INSERT UPDATE DELETE;
```

14

SQL Statements: CREATE LIBRARY to CREATE SCHEMA

This chapter contains the following SQL statements:

- CREATE LIBRARY
- CREATE LOCKDOWN PROFILE
- CREATE LOGICAL PARTITION TRACKING
- CREATE MATERIALIZED VIEW
- CREATE MATERIALIZED VIEW LOG
- CREATE MATERIALIZED ZONEMAP
- CREATE MLE ENV
- CREATE MLE MODULE
- CREATE OPERATOR
- CREATE OUTLINE
- CREATE PACKAGE
- CREATE PACKAGE BODY
- CREATE PFILE
- CREATE PLUGGABLE DATABASE
- CREATE PMEM FILESTORE
- CREATE PROCEDURE
- CREATE PROFILE
- CREATE PROPERTY GRAPH
- CREATE RESTORE POINT
- CREATE ROLE
- CREATE ROLLBACK SEGMENT
- CREATE SCHEMA

CREATE LIBRARY

Purpose

Use the `CREATE LIBRARY` statement to create a schema object associated with an operating-system shared library. The name of this schema object can then be used in the *`call_spec`* of `CREATE FUNCTION` or `CREATE PROCEDURE` statements, or when declaring a function or procedure in a package or type, so that SQL and PL/SQL can call to third-generation-language (3GL) functions and procedures.

> **See Also:**
>
> CREATE FUNCTION and *Oracle Database PL/SQL Language Reference* for more information on functions and procedures

Prerequisites

The `CREATE LIBRARY` statement is valid only on platforms that support shared libraries and dynamic linking.

To create a library in your own schema, you must have the `CREATE LIBRARY` system privilege. To create a library in another user's schema, you must have the `CREATE ANY LIBRARY` system privilege.

To use the library in the *`call_spec`* of a `CREATE FUNCTION` statement, or when declaring a function in a package or type, you must have the `EXECUTE` object privilege on the library and the `CREATE FUNCTION` system privilege. Refer to *Oracle Database PL/SQL Language Reference* for information on the *`call_spec`* of a `CREATE FUNCTION` statement.

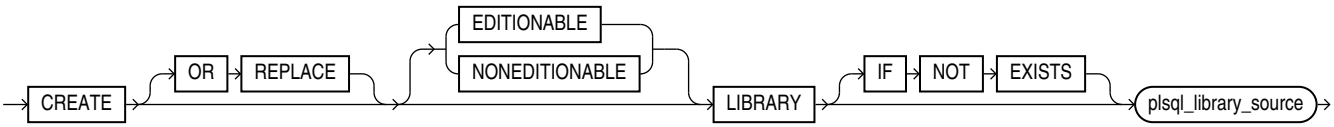
To use the library in the *`call_spec`* of a `CREATE PROCEDURE` statement, or when declaring a procedure in a package or type, you must have the `EXECUTE` object privilege on the library and the `CREATE PROCEDURE` system privilege. Refer to *Oracle Database PL/SQL Language Reference* for information on the *`call_spec`* of a `CREATE PROCEDURE` statement.

To execute a procedure or function defined with the *`call_spec`* (including a procedure or function defined within a package or type), you must have the `EXECUTE` object privilege on the procedure or function (but you do not need the `EXECUTE` object privilege on the library).

Syntax

Libraries are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

***create_library*::=**



(*`plsql_library_source`*: See *Oracle Database PL/SQL Language Reference*.)

Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the library if it already exists. Use this clause to change the definition of an existing library without dropping, re-creating, and regranting object privileges granted on it.

Users who had previously been granted privileges on a redefined library can still access the library without being regranted the privileges.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the library does not exist, a new library is created at the end of the statement.
- If the library exists, this is the library you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement`.

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement`.

[EDITIONABLE | NONEDITIONABLE]

Use these clauses to specify whether the library is an editioned or noneditioned object if editioning is enabled for the schema object type `LIBRARY` in *`schema`*. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

plsql_library_source

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the *`plsql_library_source`*.

CREATE LOCKDOWN PROFILE

Purpose

Use the `CREATE LOCKDOWN PROFILE` statement to create a PDB lockdown profile. You can use PDB lockdown profiles in a multitenant container database (CDB) to restrict user operations in PDBs.

After you create a PDB lockdown profile, you can add restrictions to the profile with the `ALTER LOCKDOWN PROFILE` statement. You can restrict user operations associated with certain database features, options, and SQL statements.

When a lockdown profile is assigned to a PDB, users in that PDB cannot perform the operations that are the disabled for the profile. To assign a lockdown profile, set its name for the value of the `PDB_LOCKDOWN` initialization parameter. You can assign a lockdown profile to individual PDBs, or to all PDBs in a CDB or application container, as follows:

- If you set `PDB_LOCKDOWN` while connected to a CDB root, then the lockdown profile applies to all PDBs in the CDB. It does not apply to the CDB root.
- If you set `PDB_LOCKDOWN` while connected to an application root, then the lockdown profile applies to the application root and all PDBs in the application container.
- If you set `PDB_LOCKDOWN` while connected to a particular PDB, then the lockdown profile applies to that PDB and overrides the lockdown profile for the CDB or application container, if one exists.

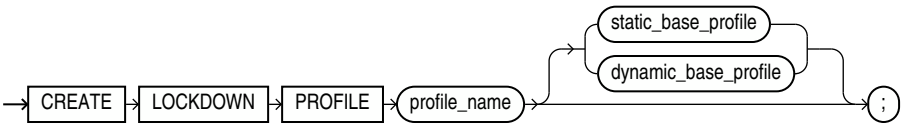
> **See Also:**
>
> - ALTER LOCKDOWN PROFILE and DROP LOCKDOWN PROFILE
> - *Oracle Database Security Guide* for more information on PDB lockdown profiles

Prerequisites

- The `CREATE LOCKDOWN PROFILE` statement must be issued from the CDB or the Application Root.
- You must have the `CREATE LOCKDOWN PROFILE` system privilege in the container in which the statement is issued.
- The PDB lockdown profile name must be unique in the container in which the statement is issued.

Syntax

***create_lockdown_profile*::=**



***static_base_profile* ::=**

***dynamic_base_profile* ::=**

Semantics

profile_name

You can create a new PDB lockdown profile with a name that you specify. The name must satisfy the requirements listed in “Database Object Naming Rules ”. The lockdown profile can be derived from a static, or dynamic base profile.

static_base_profile

Use this option to create a new lockdown profile with a base profile. The rules of the base profile in effect at profile creation time will be copied to the new lockdown profile. Changes to the base profile after the lockdown profile is created will not apply to the lockdown profile.

dynamic_base_profile

Use this option to create a new lockdown profile that will change with changes to the base profile. The new lockdown profile will inherit `DISABLE` rules of the base profile as well and subsequent changes to the base profile. The rules of the base profile have precedence in any conflict with rules that may be explicitly added to the lockdown profile. For example, the `OPTION_VALUE` clause of the base profile takes precedence over the `OPTION_VALUE` clause of the dynamic base profile.

Example

The following statement creates PDB lockdown profile `hr_prof` with a dynamic base profile `PRIVATE_DBAAS`:

```
CREATE LOCKDOWN PROFILE hr_prof INCLUDING PRIVATE_DBAAS;
```

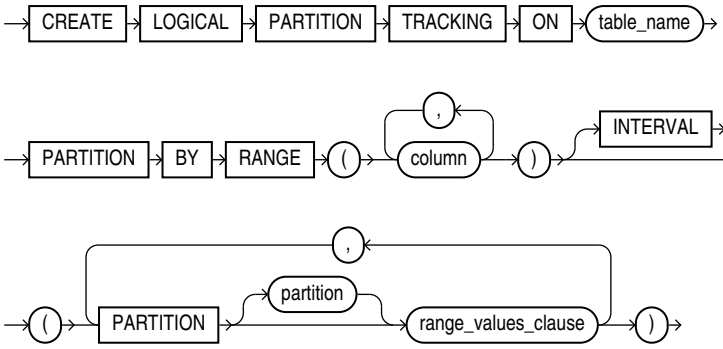
CREATE LOGICAL PARTITION TRACKING

Purpose

Use the `CREATE LOGICAL PARTITION TRACKING` statement to define a logical partitioning scheme on a table for being leveraged by materialized views and logical partition change tracking. You can define the logical partitions of your tables independently of any existing or non-existing partitioning schema of a table.

Syntax

***create_logical_partition_tracking*::=**



Semantics

Logical partition tracking is supported on a single key column within the table. The datatype of the key column can be of the following data types: `NUMBER`, `DATE`, `CHAR`, `VARCHAR`, `VARCHAR2`, `TIMESTAMP`, `TIMSTAMP WITH TIME ZONE`.

Only `RANGE` and `INTERVAL` logical partitions are supported on the base table.

> **See Also:**
>
> - *Refreshing Materialized Views* of the *Data Warehousing Guide*.

CREATE MATERIALIZED VIEW

Purpose

Use the `CREATE MATERIALIZED VIEW` statement to create a **materialized view**. A materialized view is a database object that contains the results of a query. The `FROM` clause of the query can name tables, views, and other materialized views. Collectively these objects are called **master tables** (a replication term) or **detail tables** (a data warehousing term). This reference uses "master tables" for consistency. The databases containing the master tables are called the **master databases**.

> **Note:**
>
> The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

For replication purposes, materialized views allow you to maintain read-only copies of remote data on your local node. You can select data from a materialized view as you would from a table or view. In replication environments, the materialized views commonly created are **primary key**, **rowid**, **object**, and **subquery** materialized views.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information on the types of materialized views used to support replication

For data warehousing purposes, the materialized views commonly created are **materialized aggregate views**, **single-table materialized aggregate views**, and **materialized join views**. All three types of materialized views can be used by query rewrite, an optimization technique that transforms a user request written in terms of master tables into a semantically equivalent request that includes one or more materialized views.

> **See Also:**
>
> - ALTER MATERIALIZED VIEW
> - *Oracle Database Data Warehousing Guide* for information on the types of materialized views used to support data warehousing

Prerequisites

The privileges required to create a materialized view should be granted directly rather than through a role.

To create a materialized view **in your own schema:**

- You must have been granted the CREATE MATERIALIZED VIEW system privilege **and** either the CREATE TABLE or CREATE ANY TABLE system privilege.
- You must also have access to any master tables of the materialized view that you do not own, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a materialized view **in another user's schema:**

- You must have the CREATE ANY MATERIALIZED VIEW system privilege.
- The owner of the materialized view must have the CREATE TABLE system privilege. The owner must also have access to any master tables of the materialized view that the schema owner does not own (for example, if the master tables are on a remote database) and to any materialized view logs defined on those master tables, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a refresh-on-commit materialized view (REFRESH ON COMMIT clause), in addition to the preceding privileges, you must have the ON COMMIT REFRESH object privilege on any master tables that you do not own or you must have the ON COMMIT REFRESH system privilege.

To create the materialized view **with query rewrite enabled**, in addition to the preceding privileges:

- If the schema owner does not own the master tables, then the schema owner must have the GLOBAL QUERY REWRITE privilege or the QUERY REWRITE object privilege on each table outside the schema.
- If you are defining the materialized view on a prebuilt container (ON PREBUILT TABLE clause), then you must have the READ or SELECT privilege WITH GRANT OPTION on the container table.

The user whose schema contains the materialized view must have sufficient quota in the target tablespace to store the master table and index of the materialized view or must have the UNLIMITED TABLESPACE system privilege.

When you create a materialized view, Oracle Database creates one internal table and at least one index, and may create one view, all in the schema of the materialized view. Oracle Database uses these objects to maintain the materialized view data. You must have the privileges necessary to create these objects.

You can create the following types of local materialized views (including both ON COMMIT and ON DEMAND) on master tables with commit SCN-based materialized view logs:

- Materialized aggregate views, including materialized aggregate views on a single table
- Materialized join views
- Primary-key-based and rowid-based single table materialized views
- UNION ALL materialized views, where each UNION ALL branch is one of the above materialized view types

You cannot create remote materialized views on master tables with commit SCN-based materialized view logs.

Creating a materialized view on master tables with different types of materialized view logs (that is, a master table with timestamp-based materialized view logs and a master table with commit SCN-based materialized view logs) is not supported and causes ORA-32414.

To specify an edition in the *evaluation_edition_clause* or the *unusable_editions_clause*, you must have the `USE` privilege on the edition.

To perform select from a materialized view, you must have the `SELECT ANY TABLE` system privilege.

See Also:

- CREATE TABLE, CREATE VIEW , and CREATE INDEX for information on these privileges
- *Oracle Database Administrator's Guide* for information about the prerequisites that apply to creating replication materialized views
- *Oracle Database Data Warehousing Guide* for information about the prerequisites that apply to creating data warehousing materialized views

Semantics

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the view does not exist, a new view is created at the end of the statement.
- If the view exists, this is the view you have at the end of the statement. A new one is not created because the older one is detected.

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement`.

annotations_clause

For the full semantics of the annotations clause see *annotations_clause*.

schema

Specify the schema to contain the materialized view. If you omit *schema*, then Oracle Database creates the materialized view in your schema.

materialized_view

Specify the name of the materialized view to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ". Oracle Database generates names for the table and indexes used to maintain the materialized view by adding a prefix or suffix to the materialized view name.

column_alias

You can specify a column alias for each column of the materialized view. The column alias list explicitly resolves any column name conflict, eliminating the need to specify aliases in the SELECT clause of the materialized view. If you specify any column alias in this clause, then you must specify an alias for each data source referenced in the SELECT clause.

ENCRYPT clause

Use this clause to encrypt this column of the materialized view. Refer to the CREATE TABLE clause *encryption_spec* for more information on column encryption.

OF *object_type*

The OF *object_type* clause lets you explicitly create an **object materialized view** of type *object_type*.

> **See Also:**
>
> See CREATE TABLE ... *object_table* for more information on the OF *type_name* clause

scoped_table_ref_constraint

Use the SCOPE FOR clause to restrict the scope of references to a single object table. You can refer either to the table name with *scope_table_name* or to a column alias. The values in the REF column or attribute point to objects in *scope_table_name* or *c_alias*, in which object instances of the same type as the REF column are stored. If you specify aliases, then they must have a one-to-one correspondence with the columns in the SELECT list of the defining query of the materialized view.

> **See Also:**
>
> "SCOPE REF Constraints" for more information

DEFAULT COLLATION

Use this clause to specify the default collation for the materialized view. The default collation is used as the derived collation for all the character literals included in the defining query of the materialized view. The default collation is not used by the materialized view columns; the collations for the materialized view columns are derived from the materialized view's defining subquery. The `CREATE MATERIALIZED VIEW` statement fails with an error, or the materialized view is created in an invalid state, if any of its character columns is based on an expression in the defining subquery that has no derived collation.

For *`collation_name`*, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the materialized view is set to the effective schema default collation of the schema containing the materialized view. Refer to the DEFAULT_COLLATION clause of `ALTER SESSION` for more information on the effective schema default collation.

You can specify the `DEFAULT COLLATION` clause only if the `COMPATIBLE` initialization parameter is set to `12.2` or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

To change the default collation for a materialized view, you must recreate the materialized view.

Restrictions on the Default Collation for Materialized Views

The following restrictions apply when specifying the default collation for a materialized view:

- If the defining query of the materialized view contains the `WITH` *`plsql_declarations`* clause, then the default collation of the materialized view must be `USING_NLS_COMP`.
- If the materialized view is created on a prebuilt table, then the declared collations of the table columns must be the same as the corresponding collations of the materialized view columns, as derived from the defining query.

ON PREBUILT TABLE Clause

The `ON PREBUILT TABLE` clause lets you register an existing table as a preinitialized materialized view. This clause is particularly useful for registering large materialized views in a data warehousing environment. The table must have the same name and be in the same schema as the resulting materialized view.

If the materialized view is dropped, then the preexisting table reverts to its identity as a table.

> **Note:**
>
> This clause assumes that the table object reflects the materialization of a subquery. Oracle strongly recommends that you ensure that this assumption is true in order to ensure that the materialized view correctly reflects the data in its master tables.

The `ON PREBUILT TABLE` clause could be useful in the following scenarios:

- You have a table representing the result of a query. Creating the table was an expensive operation that possibly took a long time. You want to create a materialized view on the query. You can use the `ON PREBUILT TABLE` clause to avoid the expense of executing the query and populating the container for the materialized view.

- You temporarily discontinue having a materialized view, but keep its container table, using the `DROP MATERIALIZED VIEW ... PRESERVE TABLE` statement. You then decide to recreate the materialized view and you know that the master tables of the view have not changed. You can create the materialized view using the `ON PREBUILT TABLE` clause. This avoids the expense and time of creating and populating the container table for the materialized view.

If you specify `ON PREBUILT TABLE`, then Oracle database does not create the `I_SNAP$` index. This index improves fast refresh performance. If you want the benefits of this index, then you can create it manually. Refer to *Oracle Database Data Warehousing Guide* for more information.

WITH REDUCED PRECISION

Specify `WITH REDUCED PRECISION` to authorize the loss of precision that will result if the precision of the table or materialized view columns do not exactly match the precision returned by *`subquery`*.

WITHOUT REDUCED PRECISION

Specify `WITHOUT REDUCED PRECISION` to require that the precision of the table or materialized view columns match exactly the precision returned by *`subquery`*, or the create operation will fail. This is the default.

Restrictions on Using Prebuilt Tables

Prebuilt tables are subject to the following restrictions:

- Each column alias in *`subquery`* must correspond to a column in the prebuilt table, and corresponding columns must have matching data types.
- If you specify this clause, then you cannot specify a `NOT NULL` constraint for any column that is not referenced in *`subquery`* unless you also specify a default value for that column.
- You cannot specify the `ON PREBUILT TABLE` clause when creating a rowid materialized view.

> **See Also:**
>
> "Creating Prebuilt Materialized Views: Example"

physical_properties_clause

The components of the *`physical_properties_clause`* have the same semantics for materialized views that they have for tables, with exceptions and additions described in the sections that follow.

Restriction on the *physical_properties_clause*

You cannot specify `ORGANIZATION EXTERNAL` for a materialized view.

deferred_segment_creation

Use this clause to determine when the segment for this materialized view should be created. See the `CREATE TABLE` clause *deferred_segment_creation* for more information.

segment_attributes_clause

Use the *`segment_attributes_clause`* to establish values for the `PCTFREE`, `PCTUSED`, and `INITRANS` parameters, the storage characteristics for the materialized view, to assign a

tablespace, and to specify whether logging is to occur. In the `USING INDEX` clause, you cannot specify `PCTFREE` or `PCTUSED`.

TABLESPACE Clause

Specify the tablespace in which the materialized view is to be created. If you omit this clause, then Oracle Database creates the materialized view in the default tablespace of the schema containing the materialized view.

> **See Also:**
>
> *physical_attributes_clause* and storage_clause for a complete description of these clauses, including default values

logging_clause

Specify `LOGGING` or `NOLOGGING` to establish the logging characteristics for the materialized view. The logging characteristic affects the creation of the materialized view and any nonatomic refresh that is initiated by way of the `DBMS_REFRESH` package. The default is the logging characteristic of the tablespace in which the materialized view resides.

> **See Also:**
>
> *logging_clause* for a full description of this clause and *Oracle Database PL/SQL Packages and Types Reference* for more information on atomic and nonatomic refresh

table_compression

Use the *table_compression* clause to instruct the database whether to compress data segments to reduce disk and memory use. This clause has the same semantics in `CREATE MATERIALIZED VIEW` and `CREATE TABLE`. Refer to the *table_compression* clause in the documentation on `CREATE TABLE` for the full semantics of this clause.

inmemory_table_clause

Use the *inmemory_table_clause* to enable or disable the materialized view for the In-Memory Column Store (IM column store). This clause has the same semantics as the *inmemory_table_clause* in the `CREATE TABLE` documentation.

inmemory_column_clause

Use the *inmemory_column_clause* to disable specific materialized view columns for the IM column store, and to specify the data compression method for specific columns. This clause has the same semantics here as it has for the *inmemory_column_clause* in the `CREATE TABLE` documentation, with the following addition: If you specify the *inmemory_column_clause*, then you must also specify a *column_alias* for each column in the materialized view.

index_org_table_clause

The `ORGANIZATION INDEX` clause lets you create an index-organized materialized view. In such a materialized view, data rows are stored in an index defined on the primary key of the

materialized view. You can specify index organization for the following types of materialized views:

- Read-only and updatable object materialized views. You must ensure that the master table has a primary key.
- Read-only and updatable primary key materialized views.
- Read-only rowid materialized views.

The keywords and parameters of the *index_org_table_clause* have the same semantics as described in CREATE TABLE, with the restrictions that follow.

> **See Also:**
>
> The *index_org_table_clause* of CREATE TABLE

Restrictions on Index-Organized Materialized Views

Index-organized materialized views are subject to the following restrictions:

- You cannot specify the following CREATE MATERIALIZED VIEW clauses: CACHE or NOCACHE, CLUSTER, or ON PREBUILT TABLE.
- In the *index_org_table_clause*:
  - You cannot specify the *mapping_table_clause*.
  - You can specify COMPRESS only for a materialized view based on a composite primary key. You can specify NOCOMPRESS for a materialized view based on either a simple or composite primary key.

CLUSTER Clause

The CLUSTER clause lets you create the materialized view as part of the specified cluster. A cluster materialized view uses the space allocation of the cluster. Therefore, you do not specify physical attributes or the TABLESPACE clause with the CLUSTER clause.

Restriction on Cluster Materialized Views

If you specify CLUSTER, then you cannot specify the *table_partitioning_clauses* in *materialized_view_props*.

materialized_view_props

Use these property clauses to describe a materialized view that is not based on an existing table. To create a materialized view that is based on an existing table, use the ON PREBUILT TABLE clause.

column_properties

The *column_properties* clause lets you specify the storage characteristics of a LOB, nested table, varray, or XMLType column. The *object_type_col_properties* are not relevant for a materialized view.

> **See Also:**
>
> CREATE TABLE for detailed information about specifying the parameters of this clause

table_partitioning_clauses

The *table_partitioning_clauses* let you specify that the materialized view is partitioned on specified ranges of values or on a hash function. Partitioning of materialized views is the same as partitioning of tables.

> **See Also:**
>
> *table_partitioning_clauses* in the CREATE TABLE documentation

CACHE | NOCACHE

For data that will be accessed frequently, CACHE specifies that the blocks retrieved for this table are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables. NOCACHE specifies that the blocks are placed at the least recently used end of the LRU list.

> **Note:**
>
> NOCACHE has no effect on materialized views for which you specify KEEP in the *storage_clause*.

> **See Also:**
>
> CREATE TABLE for information about specifying CACHE or NOCACHE

parallel_clause

The *parallel_clause* lets you indicate whether parallel operations will be supported for the materialized view and sets the default degree of parallelism for queries and DML on the materialized view after creation.

For complete information on this clause, refer to *parallel_clause* in the documentation on CREATE TABLE.

build_clause

The *build_clause* lets you specify when to populate the materialized view.

IMMEDIATE

Specify IMMEDIATE to indicate that the materialized view is to be populated immediately. This is the default.

DEFERRED

Specify `DEFERRED` to indicate that the materialized view is to be populated by the next `REFRESH` operation. The first (deferred) refresh must always be a complete refresh. Until then, the materialized view has a staleness value of `UNUSABLE`, so it cannot be used for query rewrite.

USING INDEX Clause

The `USING INDEX` clause lets you establish the value of the `INITRANS` and `STORAGE` parameters for the default index Oracle Database uses to maintain the materialized view data. If `USING INDEX` is not specified, then default values are used for the index. Oracle Database uses the default index to speed up incremental (`FAST`) refresh of the materialized view.

Restriction on USING INDEX clause

You cannot specify the `PCTUSED` parameter in this clause.

USING NO INDEX Clause

Specify `USING NO INDEX` to suppress the creation of the default index. You can create an alternative index explicitly by using the `CREATE INDEX` statement. You should create such an index if you specify `USING NO INDEX` and you are creating the materialized view with the fast refresh method (`REFRESH FAST`).

create_mv_refresh

Use the *`create_mv_refresh`* clause to specify the default methods, modes, and times for the database to refresh the materialized view. If the master tables of a materialized view are modified, then the data in the materialized view must be updated to make the materialized view accurately reflect the data currently in its master tables. This clause lets you schedule the times and specify the method and mode for the database to refresh the materialized view.

Restriction on Synchronous Refresh

If you are using the synchronous refresh method, then you must specify `ON DEMAND` and `USING TRUSTED CONSTRAINTS`.

> **Note:**
>
> This clause only sets the default refresh options. For instructions on actually implementing the refresh, refer to *Oracle Database Administrator's Guide* and *Oracle Database Data Warehousing Guide*.

> **See Also:**
>
> - "Periodic Refresh of Materialized Views: Example" and "Automatic Refresh Times for Materialized Views: Example"
> - *Oracle Database PL/SQL Packages and Types Reference* for more information on refresh methods
> - *Oracle Database Data Warehousing Guide* to learn how to use refresh statistics to monitor the performance of materialized view refresh operations

FAST Clause

Specify `FAST` to indicate the fast refresh method, which performs the refresh according to the changes that have occurred to the master tables. The changes for conventional DML changes are stored in the materialized view log associated with the master table. The changes for direct-path `INSERT` operations are stored in the direct loader log.

If you specify `REFRESH FAST`, then the `CREATE` statement will fail unless materialized view logs already exist for the materialized view master tables. Oracle Database creates the direct loader log automatically when a direct-path `INSERT` takes place. No user intervention is needed.

For both conventional DML changes and for direct-path `INSERT` operations, other conditions may restrict the eligibility of a materialized view for fast refresh.

Restrictions on FAST Refresh

`FAST` refresh is subject to the following restrictions:

- When you specify `FAST` refresh at create time, Oracle Database verifies that the materialized view you are creating is eligible for fast refresh. When you change the refresh method to `FAST` in an `ALTER MATERIALIZED VIEW` statement, Oracle Database does not perform this verification. If the materialized view is not eligible for fast refresh, then Oracle Database returns an error when you attempt to refresh this view.
- Materialized views are not eligible for fast refresh if the defining query contains an analytic function or the `XMLTable` function.
- Materialized views are not eligible for fast refresh if the defining query references a table on which an `XMLIndex` index is defined.
- You cannot fast refresh a materialized view if any of its columns is encrypted.

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for restrictions on fast refresh in replication environments
> - *Oracle Database Data Warehousing Guide* for restrictions on fast refresh in data warehousing environments
> - The `EXPLAIN_MVIEW` procedure of the `DBMS_MVIEW` package for help diagnosing problems with fast refresh and the `TUNE_MVIEW` procedure of the `DBMS_MVIEW` package for correction of query rewrite problems
> - "Analytic Functions "
> - "Creating a Fast Refreshable Materialized View: Example"

COMPLETE Clause

Specify `COMPLETE` to indicate the complete refresh method, which is implemented by executing the defining query of the materialized view. If you request a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

FORCE Clause

Specify `FORCE` to indicate that when a refresh occurs, Oracle Database will perform a fast refresh if one is possible or a complete refresh if fast refresh is not possible. If you do not specify a refresh method (`FAST`, `COMPLETE`, or `FORCE`), then `FORCE` is the default.

ON COMMIT Clause

Specify `ON COMMIT` to indicate that a refresh is to occur whenever the database commits a transaction that operates on a master table of the materialized view. This clause may increase the time taken to complete the commit, because the database performs the refresh operation as part of the commit process.

You can specify only one of the `ON COMMIT`, `ON DEMAND`, and `ON STATEMENT` clauses. If you specify `ON COMMIT`, then you cannot also specify `START WITH` or `NEXT`.

Restrictions on Refreshing ON COMMIT

The following restrictions apply to the `ON COMMIT` clause:

- This clause is not supported for materialized views containing object types or Oracle-supplied types.
- This clause is not supported for materialized views with remote tables.
- If you specify this clause, then you cannot subsequently execute a distributed transaction on any master table of this materialized view. For example, you cannot insert into the master by selecting from a remote table. The `ON DEMAND` clause does not impose this restriction on subsequent distributed transactions on master tables.

ON DEMAND Clause

Specify `ON DEMAND` to indicate that database will not refresh the materialized view unless the user manually launches a refresh through one of the three `DBMS_MVIEW` refresh procedures.

You can specify only one of the `ON COMMIT`, `ON DEMAND`, and `ON STATEMENT` clauses. If you omit all three of these clauses, then `ON DEMAND` is the default. You can override this default setting by specifying the `START WITH` or `NEXT` clauses, either in the same `CREATE MATERIALIZED VIEW` statement or a subsequent `ALTER MATERIALIZED VIEW` statement.

`START WITH` and `NEXT` take precedence over `ON DEMAND`. Therefore, in most circumstances it is not meaningful to specify `ON DEMAND` when you have specified `START WITH` or `NEXT`.

> **See Also:**
>
> - *Oracle Database PL/SQL Packages and Types Reference* for information on these procedures
> - *Oracle Database Data Warehousing Guide* on the types of materialized views you can create by specifying `REFRESH ON DEMAND`

ON STATEMENT Clause

Specify `ON STATEMENT` to indicate that an automatic refresh is to occur every time a DML operation is performed on any of the materialized view's base tables.

You can specify only one of the `ON COMMIT`, `ON DEMAND`, and `ON STATEMENT` clauses. You can specify `ON STATEMENT` only when *creating* a materialized view. You cannot subsequently *alter* the materialized view to use `ON STATEMENT` refresh.

Restrictions on Refreshing ON STATEMENT

The following restrictions apply to the `ON STATEMENT` clause:

- This clause can be used only with materialized views that are fast refreshable. The `ON STATEMENT` clause must be specified with the `REFRESH FAST` clause.
- The base tables referenced in the materialized view's defining query must be connected in a join graph that uses the star schema or snowflake schema model. The query must contain exactly one centralized fact table and one or more dimension tables, with all pairs of joined tables being related using primary key-foreign key constraints.
  - There is no restriction on the depth of the snowflake model.
  - The constraints can be in `RELY` mode. However, you must include the `USING TRUSTED CONSTRAINT` clause while creating the materialized view to use the `RELY` constraint.
- The materialized view's defining query must include the `ROWID` column of the fact table.
- The materialized view's defining query cannot include any of the following: invisible columns, ANSI join syntax, complex query, inline view as base table, composite primary key, `LONG` columns, and LOB columns.
- You cannot alter the definition of an existing materialized view that uses the `ON STATEMENT` refresh mode.
- You cannot alter an existing materialized view and enable `ON STATEMENT` refresh for it.
- The following operations cause a materialized view with `ON STATEMENT` refresh to become unusable:
  - `UPDATE` operations on one or more dimension tables on which the materialized view is based
  - Partition maintenance operations and `TRUNCATE` operations on any base table

    However, a materialized view with the `ON STATEMENT` refresh mode can be partitioned.
- All the restrictions that apply to the `ON COMMIT` clause apply to `ON STATEMENT`.

START WITH Clause

Specify a datetime expression for the first automatic refresh time.

NEXT Clause

Specify a datetime expression for calculating the interval between automatic refreshes.

Both the `START WITH` and `NEXT` values must evaluate to a time in the future. If you omit the `START WITH` value, then the database determines the first automatic refresh time by evaluating the `NEXT` expression with respect to the creation time of the materialized view. If you specify a `START WITH` value but omit the `NEXT` value, then the database refreshes the materialized view only once. If you omit both the `START WITH` and `NEXT` values, or if you omit the *`create_mv_refresh`* entirely, then the database does not automatically refresh the materialized view.

WITH PRIMARY KEY Clause

Specify `WITH PRIMARY KEY` to create a primary key materialized view. This is the default and should be used in all cases except those described for `WITH ROWID`. Primary key materialized views allow materialized view master tables to be reorganized without affecting the eligibility of the materialized view for fast refresh. The master table must contain an enabled primary key constraint, and the defining query of the materialized view must specify all of the primary key columns directly. In the defining query, the primary key columns cannot be specified as the argument to a function such as `UPPER`.

Restriction on Primary Key Materialized Views

You cannot specify this clause for an object materialized view. Oracle Database implicitly refreshes objects materialized `WITH OBJECT ID`.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for detailed information about primary key materialized views and "Creating Primary Key Materialized Views: Example"

WITH ROWID Clause

Specify `WITH ROWID` to create a rowid materialized view. Rowid materialized views are useful if the materialized view does not include all primary key columns of the master tables. Rowid materialized views must be based on a single table and cannot contain any of the following:

- Distinct or aggregate functions
- `GROUP BY` or `CONNECT BY` clauses
- Subqueries
- Joins
- Set operations

The `WITH ROWID` clause has no effect if there are multiple master tables in the defining query.

Rowid materialized views are not eligible for fast refresh after a master table reorganization until a complete refresh has been performed.

Restriction on Rowid Materialized Views

You cannot specify this clause for an object materialized view. Oracle Database implicitly refreshes objects materialized `WITH OBJECT ID`.

> **See Also:**
>
> "Creating Materialized Aggregate Views: Example" and "Creating Rowid Materialized Views: Example"

USING ROLLBACK SEGMENT Clause

This clause is not valid if your database is in automatic undo mode, because in that mode Oracle Database uses undo tablespaces instead of rollback segments. Oracle strongly recommends that you use automatic undo mode. This clause is supported for backward compatibility with replication environments containing older versions of Oracle Database that still use rollback segments.

For *`rollback_segment`*, specify the remote rollback segment to be used during materialized view refresh.

DEFAULT

`DEFAULT` specifies that Oracle Database will choose automatically which rollback segment to use. If you specify `DEFAULT`, then you cannot specify *`rollback_segment`*. `DEFAULT` is most useful when modifying, rather than creating, a materialized view.

> **See Also:**
>
> ALTER MATERIALIZED VIEW

MASTER

`MASTER` specifies the remote rollback segment to be used at the remote master site for the individual materialized view.

LOCAL

`LOCAL` specifies the remote rollback segment to be used for the local refresh group that contains the materialized view. This is the default.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for information on specifying the local materialized view rollback segment using the `DBMS_REFRESH` package

If you omit *`rollback_segment`*, then the database automatically chooses the rollback segment to be used. One master rollback segment is stored for each materialized view and is validated during materialized view creation and refresh. If the materialized view is complex, then the database ignores any master rollback segment you specify.

USING ... CONSTRAINTS Clause

The `USING ... CONSTRAINTS` clause lets Oracle Database choose more rewrite options during the refresh operation, resulting in more efficient refresh execution. The clause lets Oracle Database use unenforced constraints, such as dimension relationships or constraints in the `RELY` state, rather than relying only on enforced constraints during the refresh operation.

The `USING TRUSTED CONSTRAINTS` clause enables you to create a materialized view on top of a table that has a non-NULL Virtual Private Database (VPD) policy on it. In this case, you must ensure that the materialized view behaves correctly. Materialized view results are computed based on the rows and columns filtered by VPD policy. Therefore, you must coordinate the materialized view definition with the VPD policy to ensure the correct results. Without the `USING TRUSTED CONSTRAINTS` clause, any VPD policy on a master table will prevent a materialized view from being created.

> **Note:**
>
> The `USING TRUSTED CONSTRAINTS` clause lets Oracle Database use dimension and constraint information that has been declared trustworthy by the database administrator but that has not been validated by the database. If the dimension and constraint information is valid, then performance may improve. However, if this information is invalid, then the refresh procedure may corrupt the materialized view even though it returns a success status.

If you omit this clause, then the default is `USING ENFORCED CONSTRAINTS`.

NEVER REFRESH Clause

Specify `NEVER REFRESH` to prevent the materialized view from being refreshed with any Oracle Database refresh mechanism or packaged procedure. Oracle Database will ignore any `REFRESH` statement on the materialized view issued from such a procedure. If you specify this clause, then you can perform DML operations on the materialized view. To reverse this clause, you must issue an `ALTER MATERIALIZED VIEW ... REFRESH` statement.

evaluation_edition_clause

You must specify this clause if *`subquery`* references an editioned object. Use this clause to specify the edition that is searched during name resolution of the editioned object—the evaluation edition.

- Specify `CURRENT EDITION` to search the edition in which this DDL statement is executed.
- Specify `EDITION` *`edition`* to search *`edition`*.
- Specifying `NULL EDITION` is equivalent to omitting the *`evaluation_edition_clause`*.

If you omit the *`evaluation_edition_clause`*, then editioned objects are invisible during name resolution and an error will result. Dropping the evaluation edition invalidates the materialized view.

> **See Also:**
>
> *Oracle Database Development Guide* for more information on specifying the evaluation edition for a materialized view

{ ENABLE | DISABLE } ON QUERY COMPUTATION

This clause lets you create a real-time materialized view or a regular view. A real-time materialized view provides fresh data to user queries even when the materialized view is not in sync with its base tables due to data changes. Instead of modifying the materialized view, the optimizer writes a query that combines the existing rows in the materialized view with changes recorded in log files (either materialized view logs or the direct loader logs). This is called on-query computation.

- Specify `ENABLE ON QUERY COMPUTATION` to create a real-time materialized view by enabling on-query computation. This allows you to directly query up-to-date data from the materialized view by specifying the `FRESH_MV` hint in the `SELECT` statement. If the materialized view is also enabled for query rewrite, then on-query computation occurs automatically during query rewrite.
- Specify `DISABLE ON QUERY COMPUTATION` to create a regular materialized view by disabling on-query computation. This is the default.

Restrictions on Real-Time Materialized Views

Real-time materialized views are subject to the following restrictions:

- Real-time materialized views cannot be used when one or more materialized view logs created on the base tables are either unusable or nonexistent.
- A real-time materialized view must be refreshable using out-of-place refresh, log-based refresh, or partition change tracking (PCT) refresh.
- A refresh-on-commit materialized view cannot be a real-time materialized view.

- If a real-time materialized view is a nested materialized view that is defined on top of one or more base materialized views, then query rewrite occurs only if all the base materialized views are fresh. If one or more base materialized views are stale, then query rewrite is not performed using this real-time materialized view.
- The cursors of queries that directly access real-time materialized views are not shared.

> **See Also:**
>
> - FRESH_MV Hint
> - *Oracle Database Data Warehousing Guide* for more information on real-time materialized views

query_rewrite_clause

The *query_rewrite_clause* lets you specify whether the materialized view is eligible to be used for query rewrite.

ENABLE Clause

Specify ENABLE to enable the materialized view for query rewrite. If you also specify the *unusable_editions_clause*, then the materialized view is not enabled for query rewrite in the unusable editions.

Restrictions on Enabling Query Rewrite

Enabling of query rewrite is subject to the following restrictions:

- You can enable query rewrite only if all user-defined functions in the materialized view are DETERMINISTIC.
- You can enable query rewrite only if expressions in the statement are repeatable. For example, you cannot include CURRENT_TIME or USER, sequence values (such as the CURRVAL or NEXTVAL pseudocolumns), or the SAMPLE clause (which may sample different rows as the contents of the materialized view change).

> **Note:**
>
> - Query rewrite is disabled by default, so you must specify this clause to make materialized views eligible for query rewrite.
> - After you create the materialized view, you must collect statistics on it using the DBMS_STATS package. Oracle Database needs the statistics generated by this package to optimize query rewrite.

> **See Also:**
>
> - *Oracle Database Data Warehousing Guide* for more information on query rewrite
> - *Oracle Database Data Warehousing Guide* to learn how to use refresh statistics to monitor the performance of materialized view refresh operations
> - *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_STATS` package
> - The `EXPLAIN_MVIEW` procedure of the `DBMS_MVIEW` package for help diagnosing problems with query rewrite and the `TUNE_MVIEW` procedure of the `DBMS_MVIEW` package for correction of query rewrite problems
> - CREATE FUNCTION

DISABLE Clause

Specify `DISABLE` to indicate that the materialized view is not eligible for use by query rewrite. A disabled materialized view can be refreshed.

unusable_editions_clause

This clause lets you specify that the materialized view is not eligible for query rewrite in one or more editions. You can specify this clause regardless of whether you specify the `ENABLE` or `DISABLE` clause. If you specify the `DISABLE` clause, then this clause will take effect if the materialized view is subsequently enabled for query rewrite using the `ALTER MATERIALIZED VIEW ... ENABLE QUERY REWRITE` statement.

UNUSABLE BEFORE Clause

This clause lets you specify that the materialized view is not eligible for query rewrite in the ancestors of an edition.

- If you specify `CURRENT EDITION`, then the materialized view is not eligible for query rewrite in the ancestors of the current edition.
- If you specify `EDITION` *`edition`*, then the materialized view is not eligible for query rewrite in the ancestors of the specified *`edition`*.

UNUSABLE BEGINNING WITH Clause

This clause lets you specify that the materialized view is not eligible for query rewrite in an edition and its descendants.

- If you specify `CURRENT EDITION`, then the materialized view is not eligible for query rewrite in the current edition and its descendants.
- If you specify `EDITION` *`edition`*, then the materialized view is not eligible for query rewrite in the specified edition and its descendants.
- Specifying `NULL EDITION` is equivalent to omitting the `UNUSABLE BEGINNING WITH` clause.

The materialized view has a dependency on each edition in which it is not eligible for query rewrite. If such an edition is subsequently dropped, then the dependency is removed. However, the materialized view is not invalidated.

ENABLE | DISABLE CONCURRENT REFRESH

Enable concurrent refresh to refresh the same on-commit atomic materialized view across multiple sessions concurrently. The materialized view is refreshed concurrently when multiple concurrent DML transactions on the same base table of the materialized view are committed.

There are no limitations on how many materialized views can be refreshed.

Concurrent refresh is disabled by default. You must explictly enable it on the materialized view. Note that you can enable it only on on-commit materialized views.

> **See Also:**
>
> *Refreshing Materialized Views* of the *Oracle Database Data Warehousing Guide*.

AS *subquery*

Specify the defining query of the materialized view. When you create the materialized view, Oracle Database executes this subquery and places the results in the materialized view. This subquery is any valid SQL subquery. However, not all subqueries are fast refreshable, nor are all subqueries eligible for query rewrite.

Notes on the Defining Query of a Materialized View

The following notes apply to materialized views:

- Oracle Database does not execute the defining query immediately if you specify `BUILD DEFERRED`.
- Oracle recommends that you qualify each table and view in the `FROM` clause of the defining query of the materialized view with the schema containing it.
- In order to create a materialized view whose defining query selects from a master table that has a Virtual Private Database (VPD) policy, you must specify the `REFRESH USING TRUSTED CONSTRAINTS` clause.

Restrictions on the Defining Query of a Materialized View

The materialized view query is subject to the following restrictions:

- The defining query of a materialized view can select from tables, views, or materialized views owned by the user `SYS`, but you cannot enable `QUERY REWRITE` on such a materialized view.
- The defining query of a materialized view cannot select from a `V$` view or a `GV$` view.
- You cannot define a materialized view with a subquery in the select list of the defining query. You can, however, include subqueries elsewhere in the defining query, such as in the `WHERE` clause.
- You cannot use the `AS OF` clause of the *`flashback_query_clause`* in the defining query of a materialized view.
- Materialized join views and materialized aggregate views with a `GROUP BY` clause cannot select from an index-organized table.
- Materialized views cannot contain columns of data type `LONG` or `LONG RAW`.
- Materialized views cannot contain virtual columns.

- You cannot create a materialized view log on a temporary table. Therefore, if the defining query references a temporary table, then this materialized view will not be eligible for `FAST` refresh, nor can you specify the `QUERY REWRITE` clause in this statement.
- If the `FROM` clause of the defining query references another materialized view, then you must always refresh the materialized view referenced in the defining query before refreshing the materialized view you are creating in this statement.
- Materialized views with join expressions in the defining query cannot have XML data type columns. The XML data types include `XMLType` and URI data type columns.

If you are creating a materialized view enabled for query rewrite, then:

- The defining query cannot contain, either directly or through a view, references to `ROWNUM`, `USER`, `SYSDATE`, remote tables, sequences, or PL/SQL functions that write or read database or package state.
- Neither the materialized view nor the master tables of the materialized view can be remote.

If you want the materialized view to be eligible for fast refresh using a materialized view log, or synchronous refresh using a staging log, then some additional restrictions apply.

> **See Also:**
>
> - *Oracle Database Data Warehousing Guide* for restrictions relating to using fast refresh and synchronous refresh
> - *Oracle Database Administrator's Guide*for more information on restrictions relating to replication
> - "Creating Materialized Join Views: Example", "Creating Subquery Materialized Views: Example", and "Creating a Nested Materialized View: Example"

Examples

The following examples require the materialized logs that are created in the "Examples" section of CREATE MATERIALIZED VIEW LOG .

Creating a Simple Materialized View: Example

The following statement creates a very simple materialized view based on the `employees` and table in the `hr` schema:

```
CREATE MATERIALIZED VIEW mv1 AS SELECT * FROM hr.employees;
```

By default, Oracle Database creates a primary key materialized view with refresh on demand only. If a materialized view log exists on `employees`, then `mv1` can be altered to be capable of fast refresh. If no such log exists, then only full refresh of `mv1` is possible. Oracle Database uses default storage properties for `mv1`. The only privileges required for this operation are the `CREATE MATERIALIZED VIEW` system privilege, and the `READ` or `SELECT` object privilege on `hr.employees`.

Creating Subquery Materialized Views: Example

The following statement creates a subquery materialized view based on the `customers` and `countries` tables in the `sh` schema at the `remote` database:

```
CREATE MATERIALIZED VIEW foreign_customers
   AS SELECT * FROM sh.customers@remote cu
```

```
   WHERE EXISTS
     (SELECT * FROM sh.countries@remote co
      WHERE co.country_id = cu.country_id);
```

Creating Materialized Aggregate Views: Example

The following statement creates and populates a materialized aggregate view on the sample `sh.sales` table and specifies the default refresh method, mode, and time. It uses the materialized view log created in "Creating a Materialized View Log for Fast Refresh: Examples", as well as the two additional logs shown here:

```
CREATE MATERIALIZED VIEW LOG ON times
   WITH ROWID, SEQUENCE (time_id, calendar_year)
   INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW LOG ON products
   WITH ROWID, SEQUENCE (prod_id)
   INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW sales_mv
   BUILD IMMEDIATE
   REFRESH FAST ON COMMIT
   AS SELECT t.calendar_year, p.prod_id,
      SUM(s.amount_sold) AS sum_sales
      FROM times t, products p, sales s
      WHERE t.time_id = s.time_id AND p.prod_id = s.prod_id
      GROUP BY t.calendar_year, p.prod_id;
```

Creating Materialized Join Views: Example

The following statement creates and populates the materialized aggregate view `sales_by_month_by_state` using tables in the sample `sh` schema. The materialized view will be populated with data as soon as the statement executes successfully. By default, subsequent refreshes will be accomplished by reexecuting the defining query of the materialized view:

```
CREATE MATERIALIZED VIEW sales_by_month_by_state
     TABLESPACE example
     PARALLEL 4
     BUILD IMMEDIATE
     REFRESH COMPLETE
     ENABLE QUERY REWRITE
     AS SELECT t.calendar_month_desc, c.cust_state_province,
        SUM(s.amount_sold) AS sum_sales
        FROM times t, sales s, customers c
        WHERE s.time_id = t.time_id AND s.cust_id = c.cust_id
        GROUP BY t.calendar_month_desc, c.cust_state_province;
```

Creating Prebuilt Materialized Views: Example

The following statement creates a materialized aggregate view for the preexisting summary table, `sales_sum_table`:

```
CREATE TABLE sales_sum_table
   (month VARCHAR2(8), state VARCHAR2(40), sales NUMBER(10,2));

CREATE MATERIALIZED VIEW sales_sum_table
   ON PREBUILT TABLE WITH REDUCED PRECISION
   ENABLE QUERY REWRITE
   AS SELECT t.calendar_month_desc AS month,
             c.cust_state_province AS state,
             SUM(s.amount_sold) AS sales
```

```
   FROM times t, customers c, sales s
   WHERE s.time_id = t.time_id AND s.cust_id = c.cust_id
   GROUP BY t.calendar_month_desc, c.cust_state_province;
```

In the preceding example, the materialized view has the same name and also has the same number of columns with the same data types as the prebuilt table. The `WITH REDUCED PRECISION` clause allows for differences between the precision of the materialized view columns and the precision of the values returned by the subquery.

Creating Primary Key Materialized Views: Example

The following statement creates the primary key materialized view `catalog` on the sample table `oe.product_information`:

```
CREATE MATERIALIZED VIEW catalog
   REFRESH FAST START WITH SYSDATE NEXT SYSDATE + 1/4096
   WITH PRIMARY KEY
   AS SELECT * FROM product_information;
```

Creating Rowid Materialized Views: Example

The following statement creates a rowid materialized view on the sample table `oe.orders`:

```
CREATE MATERIALIZED VIEW order_data REFRESH WITH ROWID
   AS SELECT * FROM orders;
```

Periodic Refresh of Materialized Views: Example

The following statement creates the primary key materialized view `emp_data` and populates it with data from the sample table `hr.employees`:

```
CREATE MATERIALIZED VIEW LOG ON employees
   WITH PRIMARY KEY
   INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW emp_data
   PCTFREE 5 PCTUSED 60
   TABLESPACE example
   STORAGE (INITIAL 50K)
   REFRESH FAST NEXT sysdate + 7
   AS SELECT * FROM employees;
```

The preceding statement does not include a `START WITH` parameter, so Oracle Database determines the first automatic refresh time by evaluating the `NEXT` value using the current `SYSDATE`. A materialized view log was created for the employee table, so Oracle Database performs a fast refresh of the materialized view every 7 days, beginning 7 days after the materialized view is created.

Because the materialized view conforms to the conditions for fast refresh, the database will perform a fast refresh. The preceding statement also establishes storage characteristics that the database uses to maintain the materialized view.

Automatic Refresh Times for Materialized Views: Example

The following statement creates the complex materialized view `all_customers` that queries the employee tables on the `remote` and `local` databases:

```
CREATE MATERIALIZED VIEW all_customers
   PCTFREE 5 PCTUSED 60
   TABLESPACE example
   STORAGE (INITIAL 50K)
   USING INDEX STORAGE (INITIAL 25K)
```

```
   REFRESH START WITH ROUND(SYSDATE + 1) + 11/24
   NEXT NEXT_DAY(TRUNC(SYSDATE), 'MONDAY') + 15/24
   AS SELECT * FROM sh.customers@remote
         UNION
      SELECT * FROM sh.customers@local;
```

Oracle Database automatically refreshes this materialized view tomorrow at 11:00 a.m. and subsequently every Monday at 3:00 p.m. The default refresh method is `FORCE`. The defining query contains a `UNION` operator, which is not supported for fast refresh, so the database will automatically perform a complete refresh.

The preceding statement also establishes storage characteristics for both the materialized view and the index that the database uses to maintain it:

- The first `STORAGE` clause establishes the sizes of the first and second extents of the materialized view as 50 kilobytes each.
- The second `STORAGE` clause, appearing with the `USING INDEX` clause, establishes the sizes of the first and second extents of the index as 25 kilobytes each.

Creating a Fast Refreshable Materialized View: Example

The following statement creates a fast-refreshable materialized view that selects columns from the `order_items` table in the sample `oe` schema, using the `UNION` set operator to restrict the rows returned from the `product_information` and `inventories` tables using `WHERE` conditions. The materialized view logs for `order_items` and `product_information` were created in the "Examples " section of `CREATE MATERIALIZED VIEW LOG`. This example also requires a materialized view log on `oe.inventories`.

```
CREATE MATERIALIZED VIEW LOG ON inventories
   WITH (quantity_on_hand);

CREATE MATERIALIZED VIEW warranty_orders REFRESH FAST AS
  SELECT order_id, line_item_id, product_id FROM order_items o
    WHERE EXISTS
    (SELECT * FROM inventories i WHERE o.product_id = i.product_id
      AND i.quantity_on_hand IS NOT NULL)
  UNION
    SELECT order_id, line_item_id, product_id FROM order_items
    WHERE quantity > 5;
```

The materialized view `warranty_orders` requires that materialized view logs be defined on `order_items` (with `product_id` as a join column) and on inventories (with `quantity_on_hand` as a filter column). See "Specifying Filter Columns for Materialized View Logs: Example" and "Specifying Join Columns for Materialized View Logs: Example".

Creating a Nested Materialized View: Example

The following example uses the materialized view from the preceding example as a master table to create a materialized view tailored for a particular sales representative in the sample `oe` schema:

```
CREATE MATERIALIZED VIEW my_warranty_orders
   AS SELECT w.order_id, w.line_item_id, o.order_date
   FROM warranty_orders w, orders o
   WHERE o.order_id = o.order_id
   AND o.sales_rep_id = 165;
```

Specify Annotations at the View Level

The following example adds annotations `Title` value `Tab1 MV1` and `Snapshot` without a value to the materialized view `MView1`:

```
CREATE MATERIALIZED VIEW MView1 ANNOTATIONS (Title 'Tab1 MV1', ADD Snapshot) AS SELECT *
from Table1;
```

Specify Annotations at the View and Column Level

The following example adds `Hidden` to column `T`, `Title` with value `Tab1 MV1`, and `Snapshot` without a value to the materialized view `MView1` :

```
CREATE MATERIALIZED VIEW MView1(T ANNOTATIONS (Hidden)) ANNOTATIONS (Title 'Tab1 MV1',
ADD Snapshot)
   AS SELECT * from Table1;
```

CREATE MATERIALIZED VIEW LOG

Purpose

Use the `CREATE MATERIALIZED VIEW LOG` statement to create a **materialized view log**, which is a table associated with the master table of a materialized view.

> **Note:**
>
> The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

Materialized view logs are used for two types of materialized view refreshes: fast refresh and synchronous refresh.

Fast refresh uses a conventional materialized view log. During a fast refresh (also called an incremental refresh), when DML changes are made to master table data, Oracle Database stores rows describing those changes in the materialized view log and then uses the materialized view log to refresh materialized views based on the master table.

Synchronous refresh uses a special type of materialized view log called a **staging log**. During a synchronous refresh, DML changes are first described in the staging log and then applied to the master tables and the materialized views simultaneously. This guarantees that the master table data and materialized view data are in sync throughout the refresh process. This refresh method is useful in data warehousing environments.

Without a materialized view log, Oracle Database must reexecute the materialized view query to refresh the materialized view. This process is called a **complete refresh**. Usually, a complete refresh takes more time to complete than a fast refresh or a synchronous refresh.

A materialized view log is located in the master database in the same schema as the master table. A master table can have only one materialized view log defined on it.

To fast refresh or synchronous refresh a materialized join view, you must create a materialized view log for each of the tables referenced by the materialized view.

Fast refresh supports two types of materialized view logs: timestamp-based materialized view logs and commit SCN-based materialized view logs. Timestamp-based materialized view logs use timestamps and require some setup operations when preparing to refresh the materialized view. Commit SCN-based materialized view logs use commit SCN data rather than timestamps, which removes the need for the setup operations and thus can improve the speed

of the materialized view refresh. If you specify the `COMMIT SCN` clause, then a commit SCN-based materialized view log is created. Otherwise, a time-stamp based materialized view log is created. Note that only new materialized view logs can take advantage of `COMMIT SCN`. Existing materialized view logs cannot be altered to add `COMMIT SCN` unless they are dropped and recreated. Refer to *Oracle Database Data Warehousing Guide* for more information.

Synchronous refresh supports only timestamp-based staging logs.

> **See Also:**
>
> - CREATE MATERIALIZED VIEW , ALTER MATERIALIZED VIEW , *Oracle Database Concepts*, *Oracle Database Data Warehousing Guide*, and *Oracle Database Administrator's Guide* for information on materialized views in general
> - ALTER MATERIALIZED VIEW LOG for information on modifying a materialized view log
> - DROP MATERIALIZED VIEW LOG for information on dropping a materialized view log
> - *Oracle Database Utilities* for information on using direct loader logs

Prerequisites

The privileges required to create a materialized view log directly relate to the privileges necessary to create the underlying objects associated with a materialized view log.

- If you own the master table, then you can create an associated materialized view log if you have the `CREATE TABLE` privilege.
- If you are creating a materialized view log for a table in another user's schema, then you must have the `CREATE ANY TABLE` and `COMMENT ANY TABLE` system privileges, as well as either the `READ` or `SELECT` object privilege on the master table or the `READ ANY TABLE` or `SELECT ANY TABLE` system privilege.

In either case, the owner of the materialized view log must have sufficient quota in the tablespace intended to hold the materialized view log or must have the `UNLIMITED TABLESPACE` system privilege.

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for more information about the prerequisites for creating a materialized view log

Restrictions

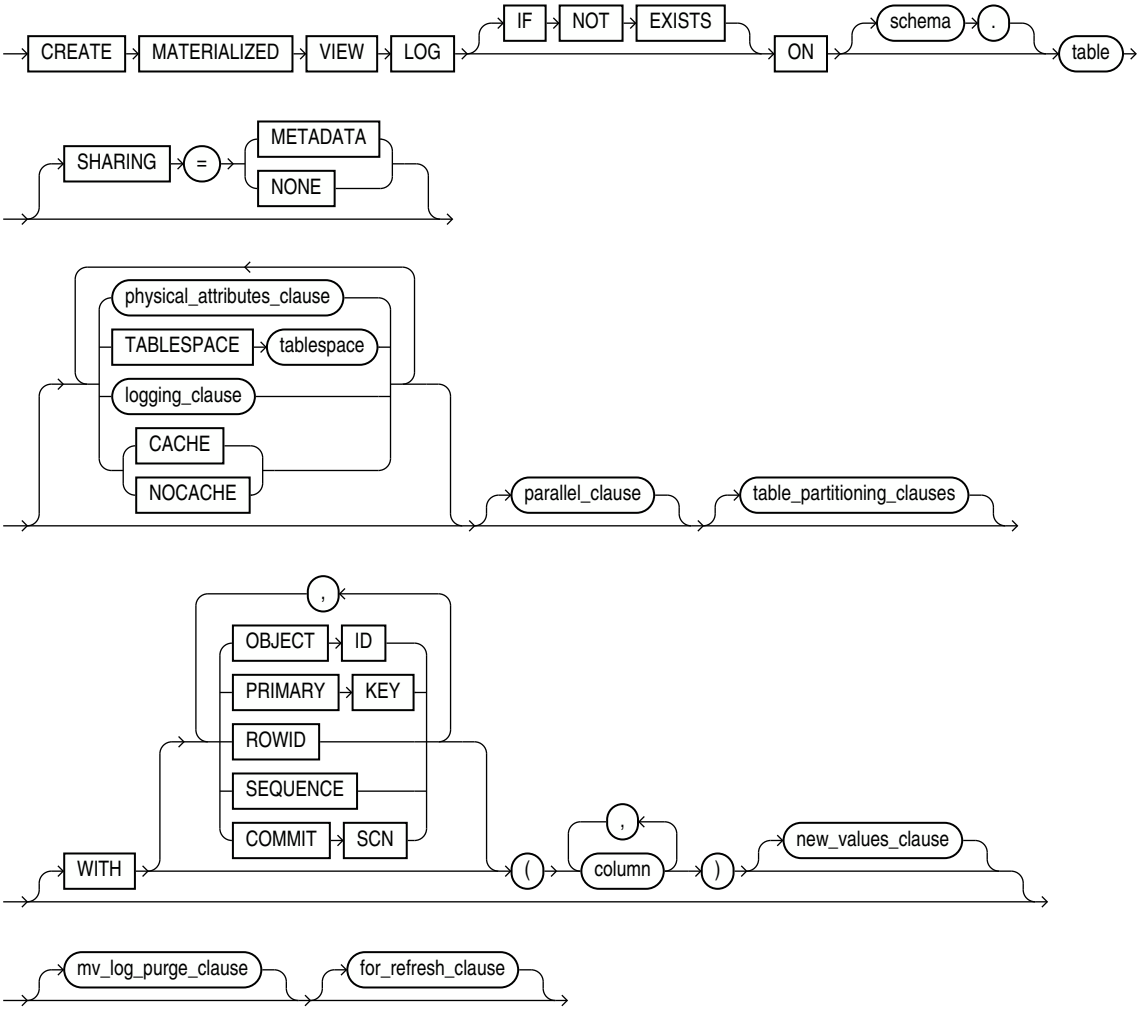
The statement `CREATE MATERIALIZED VIEW LOG` does not support the following columns in the Master Table:

- Hidden columns
- Identity columns
- `BFILE` columns

- Temporal validity columns

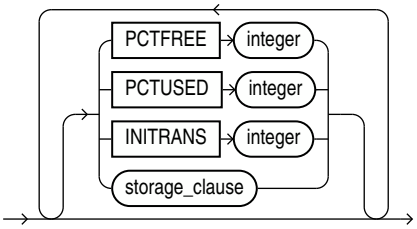
Syntax

***create_materialized_vw_log*::=**



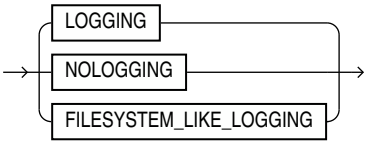
(*physical_attributes_clause*::=, *logging_clause*::=, *parallel_clause*::=, *table_partitioning_clauses*::= (in `CREATE TABLE`), *new_values_clause*::=, *mv_log_purge_clause*::=, *for_refresh_clause*::=.)

***physical_attributes_clause*::=**

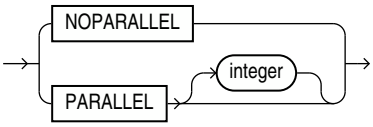


(*storage_clause*::=)

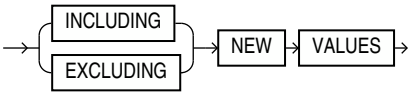
***logging_clause*::=**



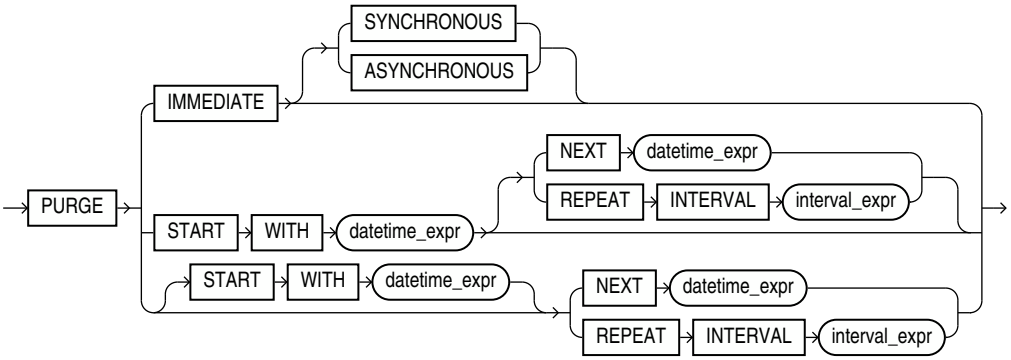
***parallel_clause*::=**



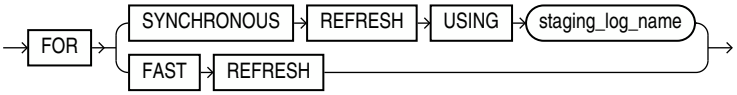
***new_values_clause*::=**



***mv_log_purge_clause*::=**



***for_refresh_clause*::=**



Semantics

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the materialized view log does not exist, a new materialized view log is created at the end of the statement.
- If the materialized view log exists, this is the materialized view log you have at the end of the statement. A new one is not created because the older materialized view log is detected.

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

schema

Specify the schema containing the materialized view log master table. If you omit *`schema`*, then Oracle Database assumes the master table is contained in your own schema. Oracle Database creates the materialized view log in the schema of its master table. You cannot create a materialized view log for a table in the schema of the user `SYS`.

table

Specify the name of the master table for which the materialized view log is to be created. Oracle Database encrypts any columns in the materialized view log that are encrypted in the master table, using the same encryption algorithm.

Restrictions on Master Tables of Materialized View Logs

The following restrictions apply to master tables of materialized view logs:

- You cannot create a materialized view log for a temporary table or for a view.
- You cannot create a materialized view log for a master table with a virtual column.

> **See Also:**
>
> "Creating a Materialized View Log for Fast Refresh: Examples"

SHARING

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- `METADATA` - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- `NONE` - The object is not shared and can only be accessed in the application root.

physical_attributes_clause

Use the *`physical_attributes_clause`* to define physical and storage characteristics for the materialized view log.

> **See Also:**
>
> *physical_attributes_clause* and storage_clause for a complete description these clauses, including default values

TABLESPACE Clause

Specify the tablespace in which the materialized view log is to be created. If you omit this clause, then the database creates the materialized view log in the default tablespace of the schema of the materialized view log.

logging_clause

Specify either `LOGGING` or `NOLOGGING` to establish the logging characteristics for the materialized view log. The default is the logging characteristic of the tablespace in which the materialized view log resides.

> **See Also:**
>
> *logging_clause* for a full description of this clause

CACHE | NOCACHE

For data that will be accessed frequently, `CACHE` specifies that the blocks retrieved for this log are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables.

`NOCACHE` specifies that the blocks are placed at the least recently used end of the LRU list. The default is `NOCACHE`.

> **Note:**
>
> `NOCACHE` has no effect on materialized view logs for which you specify `KEEP` in the *storage_clause*.

> **See Also:**
>
> CREATE TABLE for information about specifying `CACHE` or `NOCACHE`

parallel_clause

The *parallel_clause* lets you indicate whether parallel operations will be supported for the materialized view log.

For complete information on this clause, refer to *parallel_clause* in the documentation on `CREATE TABLE`.

table_partitioning_clauses

Use the *table_partitioning_clauses* to indicate that the materialized view log is partitioned on specified ranges of values or on a hash function. Partitioning of materialized view logs is the same as partitioning of tables.

> **See Also:**
>
> *table_partitioning_clauses* in the CREATE TABLE documentation

WITH Clause

Use the WITH clause to indicate whether the materialized view log should record the primary key, rowid, object ID, or a combination of these row identifiers when rows in the master are changed. You can also use this clause to add a sequence to the materialized view log to provide additional ordering information for its records.

This clause also specifies whether the materialized view log records additional columns that might be referenced as **filter columns**, which are non-primary-key columns referenced by subquery materialized views, or **join columns**, which are non-primary-key columns that define a join in the subquery WHERE clause.

If you omit this clause, or if you specify the clause without PRIMARY KEY, ROWID, or OBJECT ID, then the database stores primary key values by default. However, the database does not store primary key values implicitly if you specify only OBJECT ID or ROWID at create time. A primary key log, created either explicitly or by default, performs additional checking on the primary key constraint.

OBJECT ID

Specify OBJECT ID to indicate that the system-generated or user-defined object identifier of every modified row should be recorded in the materialized view log.

Restriction on OBJECT ID

You can specify OBJECT ID only when creating a log on an object table, and you cannot specify it for storage tables.

PRIMARY KEY

Specify PRIMARY KEY to indicate that the primary key of all rows changed should be recorded in the materialized view log.

ROWID

Specify ROWID to indicate that the rowid of all rows changed should be recorded in the materialized view log.

SEQUENCE

Specify SEQUENCE to indicate that a sequence value providing additional ordering information should be recorded in the materialized view log. Sequence numbers are necessary to support fast refresh after some update scenarios.

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for more information on the use of sequence numbers in materialized view logs and for examples that use this clause

COMMIT SCN

Without the `COMMIT SCN` clause, the materialized view log is based on timestamps and requires some setup operations when preparing to refresh the materialized view. Specify `COMMIT SCN` to instruct the database to use commit SCN data rather than timestamps. This setting removes the need for the setup operations and thus can improve the speed of the materialized view refresh.

You can create the following types of local materialized views (including both `ON COMMIT` and `ON DEMAND`) on master tables with commit SCN-based materialized view logs:

- Materialized aggregate views, including materialized aggregate views on a single table
- Materialized join views
- Primary-key-based and rowid-based single table materialized views
- `UNION ALL` materialized views, where each `UNION ALL` branch is one of the above materialized view types

You cannot create remote materialized views on master tables with commit SCN-based materialized view logs.

Restrictions on COMMIT SCN

The following restrictions apply to `COMMIT SCN`:

- Use of `COMMIT SCN` on a table with one or more LOB columns is not supported and causes `ORA-32421`.
- Creating a materialized view on master tables with different types of materialized view logs (that is, a master table with timestamp-based materialized view logs and a master table with commit SCN-based materialized view logs) is not supported and causes `ORA-32414`.
- If you specify `COMMIT SCN`, then you cannot specify `FOR SYNCHRONOUS REFRESH`.

column

Specify the columns whose values you want to be recorded in the materialized view log for all rows that are changed. Typically these columns are filter columns and join columns.

Restrictions on the WITH Clause

This clause is subject to the following restrictions:

- You can specify only one `PRIMARY KEY`, one `ROWID`, one `OBJECT ID`, one `SEQUENCE`, and one column list for each materialized view log.
- Primary key columns are implicitly recorded in the materialized view log. Therefore, you cannot specify any of the following combinations if *`column`* contains one of the primary key columns:

```
WITH ... PRIMARY KEY ... (column)
WITH ... (column) ... PRIMARY KEY
WITH (column)
```

> **See Also:**
>
> - CREATE MATERIALIZED VIEW for information on explicit and implicit inclusion of materialized view log values
> - *Oracle Database Administrator's Guide* for more information about filter columns and join columns
> - "Specifying Filter Columns for Materialized View Logs: Example" and "Specifying Join Columns for Materialized View Logs: Example"

NEW VALUES Clause

The `NEW VALUES` clause lets you determine whether Oracle Database saves both old and new values for update DML operations in the materialized view log.

> **See Also:**
>
> "Including New Values in Materialized View Logs: Example"

INCLUDING

Specify `INCLUDING` to save both new and old values in the log. If this log is for a table on which you have a single-table materialized aggregate view, and if you want the materialized view to be eligible for fast refresh, then you must specify `INCLUDING`.

EXCLUDING

Specify `EXCLUDING` to disable the recording of new values in the log. This is the default. You can use this clause to avoid the overhead of recording new values. Do not use this clause if you have a fast-refreshable single-table materialized aggregate view defined on the master table.

mv_log_purge_clause

Use this clause to specify the purge time for the materialized view log.

- `IMMEDIATE SYNCHRONOUS`: the materialized view log is purged immediately after refresh. This is the default.
- `IMMEDIATE ASYNCHRONOUS`: the materialized view log is purged in a separate Oracle Scheduler job after the refresh operation.
- `START WITH`, `NEXT`, and `REPEAT INTERVAL` set up a scheduled purge that is independent of the materialized view refresh and is initiated during `CREATE` or `ALTER MATERIALIZED VIEW LOG` statement. This is very similar to scheduled refresh syntax in a `CREATE` or `ALTER MATERIALIZED VIEW` statement:
  - The `START WITH` datetime expression specifies when the purge starts.
  - The `NEXT` datetime expression computes the next run time for the purge.

  If you specify `REPEAT INTERVAL`, then the next run time will be: `SYSDATE + interval_expr`.

  A `CREATE MATERIALIZED VIEW LOG` statement with a scheduled purge creates an Oracle Scheduler job to perform log purge. The job calls the `DBMS_SNAPSHOT.PURGE_LOG` procedure

to purge the materialized view logs. This process allows you to amortize the purging costs over several materialized view refreshes.

Restriction on *mv_log_purge_clause*

This clause is not valid for materialized view logs on temporary tables.

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for more information on purging materialized view logs

for_refresh_clause

Use this clause to specify the refresh method for which the materialized view log will be used. You can specify only one refresh method for any given master table.

FOR SYNCHRONOUS REFRESH

Specify this clause to create a staging log that can be used for synchronous refresh. Use *staging_log_name* to specify the name of the staging log to be created. The staging log will be created in the schema in which the master table resides.

After you create the staging log, you cannot perform DML operations directly on the master table. You must use the procedures in the DBMS_SYNC_REFRESH package to prepare and execute change data operations.

Restrictions on Synchronous Refresh

The following restrictions apply to synchronous refresh:

- If you specify FOR SYNCHRONOUS REFRESH, then you cannot specify COMMIT SCN.
- To be eligible for synchronous refresh, the master table must satisfy the following criteria:
  - If the master table is a fact table, then it must be partitioned.
  - The master table must have a key. If the master table is a dimension table, then it must have a primary key defined on it. If the master table is a fact table, then the set of columns that are the foreign keys of the dimension tables joined to the fact table are deemed to be the key.
  - The master table cannot have a non-NULL Virtual Private Database (VPD) policy or a trigger defined on it.

  Oracle Database may allow you to create a staging log on a master table even if all of the preceding criteria are not met. However, the master table will not be eligible for synchronous refresh.
- Any existing materialized views on the master table must be refresh-on-demand materialized views. If an existing materialized view is a refresh-on-commit materialized view, then you must change it to a refresh-on-demand materialized view with the *alter_mv_refresh* clause of ALTER MATERIALIZED VIEW before you create the staging log.

> **See Also:**
>
> - *Oracle Database Data Warehousing Guide* for the complete steps for using synchronous refresh
> - *Oracle Database PL/SQL Packages and Types Reference* for information on the `DBMS_SYNC_REFRESH` package

FOR FAST REFRESH

Specify this clause to create a materialized view log that can be used for fast refresh. The materialized view log will be created in the same schema in which the master table resides. This is the default.

Examples

Creating a Materialized View Log for Fast Refresh: Examples

The following statement creates a materialized view log on the `oe.customers` table that specifies physical and storage characteristics:

```
CREATE MATERIALIZED VIEW LOG ON customers
   PCTFREE 5
   TABLESPACE example
   STORAGE (INITIAL 10K);
```

The materialized view log on `customers` supports fast refresh for primary key materialized views only.

The following statement creates another version of the materialized view log with the `ROWID` clause, which enables fast refresh for more types of materialized views:

```
CREATE MATERIALIZED VIEW LOG ON customers WITH PRIMARY KEY, ROWID;
```

This materialized view log on `customers` makes fast refresh possible for rowid materialized views and for materialized join views. To provide for fast refresh of materialized aggregate views, you must also specify the `SEQUENCE` and `INCLUDING NEW VALUES` clauses, as shown in the example that follows.

Specify a Purge Repeat Interval for a Materialized View Log: Example

The following statement creates a materialized view log on the `oe.orders` table. The contents of the log will be purged once every five days, beginning five days after the creation date of the materialized view log:

```
CREATE MATERIALIZED VIEW LOG ON orders
  PCTFREE 5
  TABLESPACE example
  STORAGE (INITIAL 10K)
  PURGE REPEAT INTERVAL '5' DAY;
```

Specifying Filter Columns for Materialized View Logs: Example

The following statement creates a materialized view log on the `sh.sales` table and is used in "Creating Materialized Aggregate Views: Example". It specifies as filter columns all of the columns of the table referenced in that materialized view.

```
CREATE MATERIALIZED VIEW LOG ON sales
   WITH ROWID, SEQUENCE(amount_sold, time_id, prod_id)
   INCLUDING NEW VALUES;
```

Specifying Join Columns for Materialized View Logs: Example

The following statement creates a materialized view log on the `order_items` table of the sample `oe` schema. The log records primary keys and `product_id`, which is used as a join column in "Creating a Fast Refreshable Materialized View: Example".

```
CREATE MATERIALIZED VIEW LOG ON order_items WITH (product_id);
```

Including New Values in Materialized View Logs: Example

The following example creates a materialized view log on the `oe.product_information` table that specifies `INCLUDING NEW VALUES`:

```
CREATE MATERIALIZED VIEW LOG ON product_information
   WITH ROWID, SEQUENCE (list_price, min_price, category_id), PRIMARY KEY
   INCLUDING NEW VALUES;
```

You could create the following materialized aggregate view to use the `product_information` log:

```
CREATE MATERIALIZED VIEW products_mv
   REFRESH FAST ON COMMIT
   AS SELECT SUM(list_price - min_price), category_id
         FROM product_information
         GROUP BY category_id;
```

This materialized view is eligible for fast refresh because the log defined on its master table includes both old and new values.

Creating a Staging Log for Synchronous Refresh: Example

The following statement creates a staging log on the `sh.sales` fact table. The staging log is named `mystage_log` and is stored in the `sh` schema. It can be used for synchronous refresh.

```
CREATE MATERIALIZED VIEW LOG ON sales
   PCTFREE 5
   TABLESPACE example
   STORAGE (INITIAL 10K)
   FOR SYNCHRONOUS REFRESH USING mystage_log;
```

CREATE MATERIALIZED ZONEMAP

Purpose

Use the `CREATE MATERIALIZED ZONEMAP` statement to create a zone map.

A **zone map** is a special type of materialized view that stores information about zones. A **zone** is a set of contiguous data blocks on disk that stores the values of one or more table columns. Multiple zones are usually required to store all of the values of the table columns. A zone map tracks the minimum and maximum table column values stored in each zone.

Zone maps enable you to reduce the I/O and CPU costs of table scans. When a SQL statement contains predicates on columns in a zone map, the database compares the predicate values to the minimum and maximum table column values stored in each zone to determine which zones to read during SQL execution.

Oracle Database supports the following types of zone maps:

- A **basic zone map** is defined on a single table and maintains zone information for specified columns in that table.

  You can create a basic zone map either by specifying the *create_zonemap_on_table* clause, or by specifying the *create_zonemap_as_subquery* clause where the FROM clause of the defining subquery specifies a single table.

- A **join zone map** is defined on two or more joined tables and maintains zone information for specified columns in any of the joined tables.

  You can create a join zone map by specifying the *create_zonemap_as_subquery* clause. The FROM clause of the defining subquery must specify a table that is left outer joined with one or more other tables.

Zone maps are commonly used with star schemas in data warehousing environments. However, a star schema is not a requirement for creating a zone map. In either case, this reference uses star schema terminology to refer to the tables in a zone map. In a join zone map, the outer table of the join(s) is referred to as the **fact table**, and the tables with which this table is joined are referred to as **dimension tables**. Collectively these tables are called the **base tables** of the zone map. In a basic zone map, the single table on which the zone map is defined is referred to as both the fact table and the base table of the zone map.

A base table of a zone map can be a partitioned or composite-partitioned table. In this case, the zone map maintains minimum and maximum column values for each partition (and subpartition) as well as for each zone.

You can create zone maps for use with or without attribute clustering:

- To create a zone map for use with attribute clustering, use either of the following methods:
  - Use the CREATE MATERIALIZED ZONEMAP statement and include attribute clustered columns in the zone map. Refer to the *attribute_clustering_clause* of CREATE TABLE and the *attribute_clustering_clause* clause of ALTER TABLE for more information.
  - Specify the WITH MATERIALIZED ZONEMAP clause while creating or modifying an attribute clustered table. Refer to the zonemap_clause of CREATE TABLE and the MODIFY CLUSTERING clause of ALTER TABLE for more information.
- To create a zone map for use without attribute clustering, use the CREATE MATERIALIZED ZONEMAP statement and include columns that are not attribute clustered in the zone map.

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for more information on zone maps

Prerequisites

To create a zone map **in your own schema:**

- You must have the CREATE MATERIALIZED VIEW system privilege and either the CREATE TABLE or CREATE ANY TABLE system privilege.
- You must have access to any base tables of the zone map that you do not own, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a zone map **in another user's schema:**

- You must have the CREATE ANY MATERIALIZED VIEW system privilege.

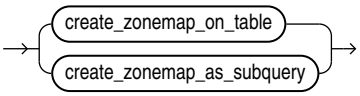
- The owner of the zone map must have the `CREATE TABLE` system privilege. The owner must also have access to any base tables of the zone map that the schema owner does not own, either through a `READ` or `SELECT` object privilege on each of the tables or through the `READ ANY TABLE` or `SELECT ANY TABLE` system privilege.

To create a refresh-on-commit zone map (`REFRESH ON COMMIT` clause), in addition to the preceding privileges, you must have the `ON COMMIT REFRESH` object privilege on any base tables that you do not own or you must have the `ON COMMIT REFRESH` system privilege. Unlike materialized views, you can create a refresh-on-commit zone map even if there are no materialized view logs on the base tables.

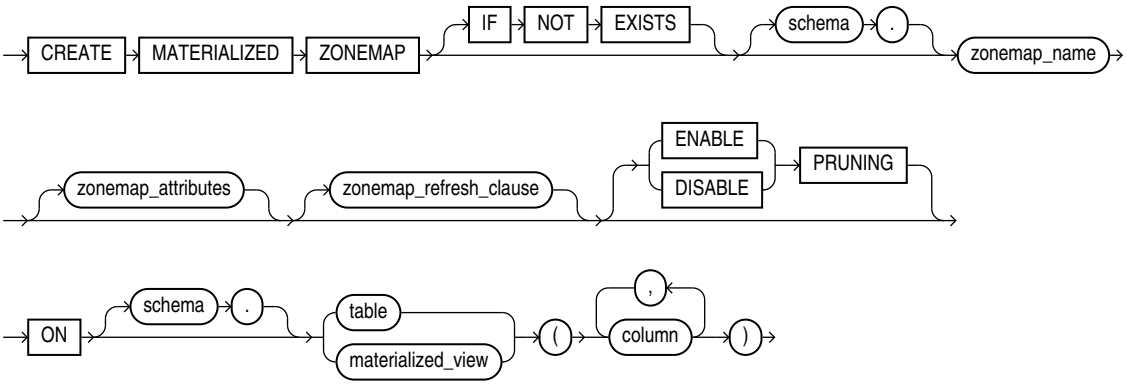
When you create a zone map, Oracle Database creates one internal table and at least one index, all in the schema of the zone map. Oracle Database uses these objects to maintain the zone map data. You must have the privileges necessary to create these objects, and you must have sufficient quota in the target tablespace to store these objects or you must have the `UNLIMITED TABLESPACE` system privilege.

Syntax

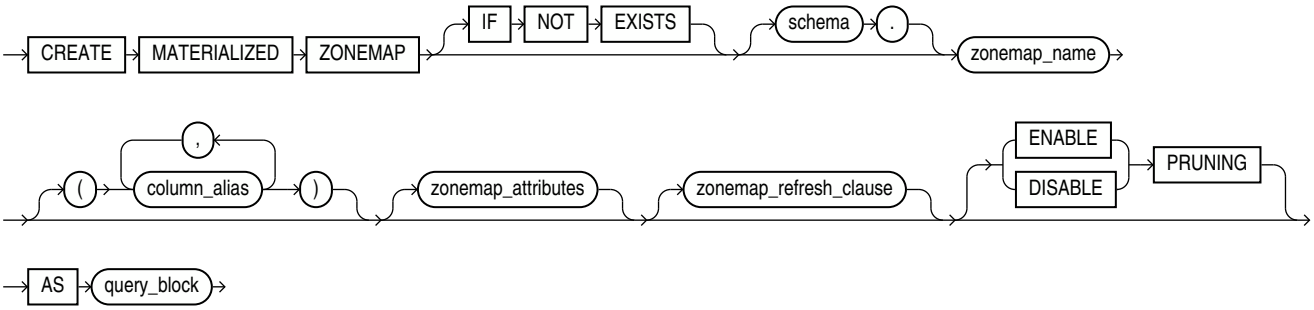
***create_materialized_zonemap*::=**



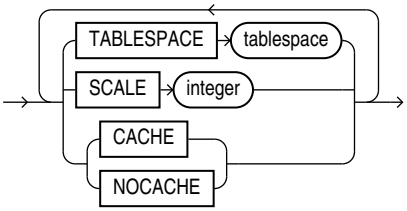
***create_zonemap_on_table*::=**



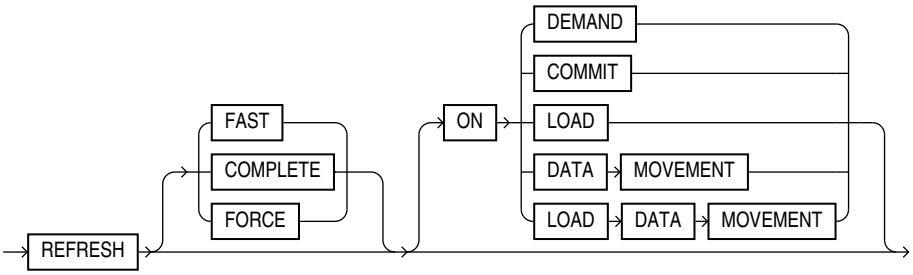
***create_zonemap_as_subquery*::=**



***zonemap_attributes*::=**



***zonemap_refresh_clause*::=**



> **Note:**
>
> When specifying the *zonemap_refresh_clause*, you must specify at least one clause after the `REFRESH` keyword.

Semantics

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the materialized zonemap does not exist, a new materialized zonemap is created at the end of the statement.
- If the materialized zonemap exists, this is the materialized zonemap you have at the end of the statement. A new one is not created because the older materialized zonemap is detected.

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

create_zonemap_on_table

Use this clause to create a basic zone map.

ON Clause

In the `ON` clause, first specify the fact table for the zone map, and then inside the parentheses specify one or more columns of the fact table to be included in the zone map.

For each specified fact table *column*, Oracle creates two columns in the zone map. These two columns contain the minimum and maximum values of the fact table column in each zone.

Oracle generates names for the zone map columns of the form `MIN_1_column` and `MAX_1_column` for the first specified fact table `column`, `MIN_2_column` and `MAX_2_column` for the second specified fact table `column`, and so on.

If you omit *schema*, then Oracle assumes the fact table is in your own schema. The fact table can be a table or a materialized view

create_zonemap_as_subquery

Use this clause to create a basic zone map or a join zone map. To create a basic zone map, specify a single base table in the `FROM` clause of the defining subquery. To create a join zone map, specify a table that is left outer joined to one or more other tables in the `FROM` clause of the defining subquery.

column_alias

You can specify a column alias for each table column to be included in the zone map. The column alias list explicitly resolves any column name conflict, eliminating the need to specify aliases in the `SELECT` list of the defining subquery. If you specify any column alias in this clause, then you must specify an alias for each column in the `SELECT` list of the defining subquery. The first column alias you specify must be `ZONE_ID$`, which corresponds to the first column in the `SELECT` list, the `SYS_OP_ZONE_ID` function expression.

AS *query_block*

Specify the defining subquery of the zone map. The subquery must consist of a single *query_block*. You can specify only the `SELECT`, `FROM`, `WHERE`, and `GROUP BY` clauses of *query_block*, and those clauses must satisfy the following requirements:

- The first column in the `SELECT` list must be the `SYS_OP_ZONE_ID` function expression. Refer to SYS_OP_ZONE_ID for more information.
- The remaining columns in the `SELECT` list must be function expressions that return minimum and maximum values for the columns you want to include in the zone map. For each column, specify a pair of function expressions of the following form:

  ```
  MIN([table.]column), MAX([table.]column)
  ```

  For *table*, specify the name or table alias for the table that contains the column. The table can be a fact table or dimension table. For *column*, specify the name or column alias for the column.
- The `FROM` clause can specify a fact table alone, or a fact table and one or more dimension tables with each dimension table left outer joined to the fact table. You can specify `LEFT [OUTER] JOIN` syntax in the `FROM` clause, or apply the outer join operator (+) to dimension table columns in the join condition in the `WHERE` clause. You can optionally specify a table alias for any of the tables in the `FROM` clause. Fact tables and dimension tables can be tables or materialized views.
- In the `WHERE` clause, you can specify only left outer join conditions using the outer join operator(+).
- You must specify a `GROUP BY` clause with the same `SYS_OP_ZONE_ID` function expression that you specified for the first column of the `SELECT` list.

schema

Specify the schema to contain the zone map. If you omit *schema*, then Oracle Database creates the zone map in your schema.

zonemap_name

Specify the name of the zone map to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

zonemap_attributes

Use this clause to specify the following attributes for the zone map: `TABLESPACE`, `SCALE`, `PCTFREE`, `PCTUSED`, and `CACHE` or `NOCACHE`.

TABLESPACE

Specify the *`tablespace`* in which the zone map is to be created. If you omit this clause, then Oracle Database creates the zone map in the default tablespace of the schema containing the zone map.

SCALE

This clause lets you specify the zone map scale, which determines the number of contiguous disk blocks that form a zone. The scale is an integer value that represents a power of 2. For example, a scale of 10 means up to 2 raised to the 10th power, or 1024, contiguous disk blocks will form a zone. For *`integer`*, specify a value between 4 and 16, inclusive. The recommended value is 10; this is the default.

PCTFREE

Specify an *`integer`* representing the percentage of space in each data block of the zone map reserved for future updates to rows of the zone map. The integer value must be between 0 and 99, inclusive. The default value is 10. Refer to *physical_attributes_clause* for more information on the `PCTFREE` parameter.

PCTUSED

Specify an *`integer`* representing the minimum percentage of used space that Oracle maintains for each data block of the zone map. The integer value must be between 0 and 99, inclusive. The default value is 40. Refer to *physical_attributes_clause* for more information on the `PCTUSED` parameter.

CACHE | NOCACHE

For data that will be accessed frequently, `CACHE` specifies that the blocks retrieved for this zone map are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed.

`NOCACHE` specifies that the blocks are placed at the least recently used end of the LRU list. The default is `NOCACHE`.

zonemap_refresh_clause

Use this clause to specify the default refresh method and mode for the zone map. If you do not specify a refresh method (`FAST`, `COMPLETE`, or `FORCE`), then `FORCE` is the default method. If you do not specify a refresh mode (`ON` clauses), then `ON LOAD DATA MOVEMENT` is the default mode.

FAST

Specify `FAST` to indicate the fast refresh method, which performs the refresh according to the changes that have occurred to the base tables. While zone maps are internally implemented as a type of materialized view, materialized view logs on base tables are not needed to perform a fast refresh of a zone map

COMPLETE

Specify `COMPLETE` to indicate the complete refresh method, which is implemented by executing the defining query of the zone map. If you request a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

FORCE

Specify `FORCE` to indicate that when a refresh occurs, Oracle Database will perform a fast refresh if one is possible or a complete refresh if fast refresh is not possible. This is the default.

ON DEMAND

Specify `ON DEMAND` to indicate that database will not refresh the zone map unless you manually issue an `ALTER MATERIALIZED ZONEMAP ... REBUILD` statement. If you specify this clause, then the zone map is referred to as a refresh-on-demand zone map. Refer to REBUILD in the documentation on `ALTER MATERIALIZED ZONEMAP` for more information on rebuilding a zone map.

ON COMMIT

Specify `ON COMMIT` to indicate that a refresh is to occur whenever the database commits a transaction that operates on a base table of the zone map. If you specify this clause, then the zone map is referred to as a refresh-on-commit zone map. This clause may increase the time taken to complete the commit, because the database performs the refresh operation as part of the commit process.

ON LOAD

Specify `ON LOAD` to indicate that a refresh is to occur at the end of a direct-path insert (serial or parallel) resulting either from an `INSERT` or a `MERGE` operation.

ON DATA MOVEMENT

Specify `ON DATA MOVEMENT` to indicate that a refresh is to occur at the end of the following data movement operations:

- Data redefinition using the `DBMS_REDEFINITION` package
- Table partition maintenance operations that are specified by the following clauses of `ALTER TABLE`: *`coalesce_table`*, *`merge_table_partitions`*, *`move_table_partition`*, and *`split_table_partition`*

ON LOAD DATA MOVEMENT

Specify `ON LOAD DATA MOVEMENT` to indicate that a refresh is to occur at the end of a direct-path insert or a data movement operation. This is the default.

ENABLE | DISABLE PRUNING

This clause lets you control the use of the zone map for pruning.

- Specify `ENABLE PRUNING` to enable use of the zone map for pruning. This is the default.
- Specify `DISABLE PRUNING` to disable use of the zone map for pruning. The optimizer will not use the zone map for pruning, but the database will continue to maintain the zone map.

If the setting is `ENABLE PRUNING`, then the optimizer will consider using the zone map for pruning during SQL operations that include any of the following conditions:

- Comparison conditions: `=`, `<=`, `<`, `>=`, `>`

The condition must be a simple comparison condition that has a column name on one side and a literal or bind variable on the other side. For example:

```
WHERE country_name = 'United States of America'
WHERE country_name = :country1
WHERE 10000 >= salary
```

- `IN` condition

  The `IN` condition must have a column name on the left side and an expression list of literals or bind variables on the right side. For example:

  ```
  WHERE country_name IN ('Germany', 'India', 'United Kingdom')
  WHERE country_name IN (:country1, :country2, :country3)
  WHERE prod_id IN (20, 48, 132, 143)
  ```

- `LIKE` condition

  The `LIKE` condition must have a column name on the left side and a text literal on the right side. The text literal is the pattern for the `LIKE` condition and it must contain at least one pattern matching character. Valid pattern matching characters are the underscore (_), which matches exactly one character, and the percent sign (%), which matches zero or more characters. The first character of the pattern cannot be a pattern matching character. For example:

  ```
  WHERE prod_name LIKE 'DVD%'
  WHERE prod_name LIKE 'Model%Cordless%Battery'
  WHERE prod_name LIKE 'CD%Pack of _'
  ```

> **See Also:**
>
> Conditions for more information on conditions

Restrictions on Zone Maps

Zone maps are subject to the following restrictions:

- A table can be a fact table for at most one zone map. A table can be a dimension table for multiple zone maps. A table can be a fact table for one zone map and a dimension table for other zone maps.
- A base table of a zone map cannot be an external table, an index-organized table, a remote table, a temporary table, or a view.
- A base table of a zone map cannot be in the schema of the user `SYS`.
- A zone map cannot be partitioned.
- You can define a zone map on a column of any scalar data type other than `BFILE`, `BLOB`, `CLOB`, `LONG`, `LONG RAW`, or `NCLOB`.
- All joins specified in the defining subquery of a zone map must be left outer equijoins with the fact table on the left side.
- If the `FROM` clause of the defining subquery for a zone map references a materialized view, then you must refresh that materialized view before refreshing the zone map.
- You cannot perform DML operations directly on a zone map.
- Each column of the zone map must have one of the following declared collations: `BINARY` or `USING_NLS_COMP`.

Examples

The following statement creates a basic zone map called `sales_zmap`. The zone map tracks columns `cust_id` and `prod_id` in the table `sales`.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  ON sales(cust_id, prod_id);
```

The following statement creates a basic zone map called `sales_zmap` that is similar to the zone map created in the previous example. However, this statement uses a defining subquery to create the zone map.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  AS SELECT SYS_OP_ZONE_ID(rowid),
            MIN(cust_id), MAX(cust_id),
            MIN(prod_id), MAX(prod_id)
     FROM sales
     GROUP BY SYS_OP_ZONE_ID(rowid);
```

The following statement creates a join zone map called `sales_zmap`. The fact table for the zone map is `sales` and the zone map has one dimension table: `customers`. The zone map tracks two columns in the dimension table: `cust_state_province` and `cust_city`.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  AS SELECT SYS_OP_ZONE_ID(s.rowid),
            MIN(cust_state_province), MAX(cust_state_province),
            MIN(cust_city), MAX(cust_city)
     FROM sales s
          LEFT OUTER JOIN customers c ON s.cust_id = c.cust_id
     GROUP BY SYS_OP_ZONE_ID(s.rowid);
```

The following statement creates a join zone map called `sales_zmap`. The fact table for the zone map is `sales` and the zone map has two dimension tables: `products` and `customers`. The zone map tracks five columns in the dimension tables: `prod_category` and `prod_subcategory` in the `products` table, and `country_id`, `cust_state_province`, and `cust_city` in the `customers` table.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  AS SELECT SYS_OP_ZONE_ID(s.rowid),
            MIN(prod_category), MAX(prod_category),
            MIN(prod_subcategory), MAX(prod_subcategory),
            MIN(country_id), MAX(country_id),
            MIN(cust_state_province), MAX(cust_state_province),
            MIN(cust_city), MAX(cust_city)
    FROM sales s
       LEFT OUTER JOIN products p ON s.prod_id = p.prod_id
       LEFT OUTER JOIN customers c ON s.cust_id = c.cust_id
    GROUP BY sys_op_zone_id(s.rowid);
```

The following statement creates a join zone map that is identical to the zone map created in the previous example. The only difference is that the previous example uses the `LEFT OUTER JOIN` syntax in the `FROM` clause and the following example uses the outer join operator (+) in the `WHERE` clause.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  AS SELECT SYS_OP_ZONE_ID(s.rowid),
            MIN(prod_category), MAX(prod_category),
            MIN(prod_subcategory), MAX(prod_subcategory),
            MIN(country_id), MAX(country_id),
            MIN(cust_state_province), MAX(cust_state_province),
```

```
       MIN(cust_city), MAX(cust_city)
FROM sales s, products p, customers c
WHERE s.prod_id = p.prod_id(+) AND
      s.cust_id = c.cust_id(+)
GROUP BY sys_op_zone_id(s.rowid);
```

CREATE MLE ENV

Purpose

MLE Environments are first-class schema objects that can be managed on their own and reused across multiple execution contexts.

MLE uses execution contexts to execute MLE language code and MLE environments allow you configure properties for these execution contexts. You can set language options to customize the runtime of the MLE language and you can enable specific MLE modules to be imported to an execution context and manage dependencies.

Use `CREATE MLE ENV` to create a new MLE environment in the database in one of three ways:

You can create an MLE environment in one of three ways :

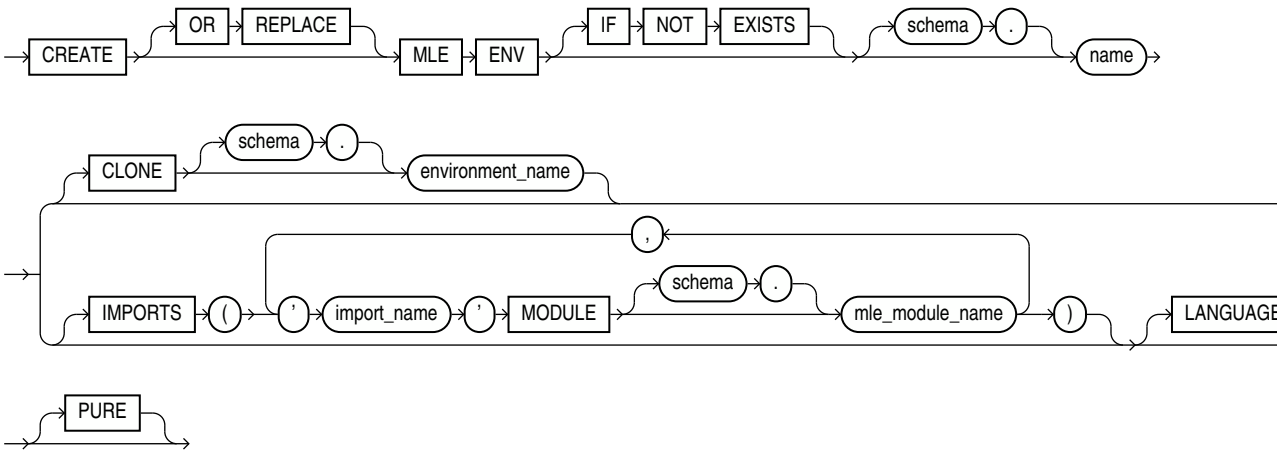
- As a fresh empty environment.
- As an environment with a list of imports and a language option string.
- By by cloning an existing environment. Cloning an environment creates an independent copy that is not affected by subsequent changes to the original environment.

MLE environments use the same namespace as tables and procedures.

Prerequisites

Users must have the `CREATE MLE` privilege to create an environment in their own schema, and the `CREATE ANY MLE` privilege to create an environment in other schemas. The user creating the environment must either own the environment being cloned or should have the `EXECUTE` privilege on it.

Syntax



Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the environment, if it already exists. You can use this clause to change the definition of an existing environment without dropping, re-creating, and regranting object privileges previously granted on it.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the MLE environment does not exist, a new MLE environment is created at the end of the statement.
- If the MLE environment, this is the MLE environment you have at the end of the statement. A new one is not created because the older one is detected.

You can have one of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the error: `REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement`.

PURE

Specify `PURE` on MLE MLE environments and JavaScript inline call specifications create restricted JavaScript execution contexts.

For more see About Restricted Execution Contexts of the *JavaScript Developer's Guide*.

Examples

The following example creates an empty MLE environment `myenv`.

```
CREATE MLE ENV scott."myenv";
```

The following example clones an existing MLE environment:

```
CREATE MLE ENV scott."myenv" CLONE "other_env";
```

See Also:

- *MLE JavaScript Modules and Environments*
- ALTER MLE ENV
- DROP MLE ENV

CREATE MLE MODULE

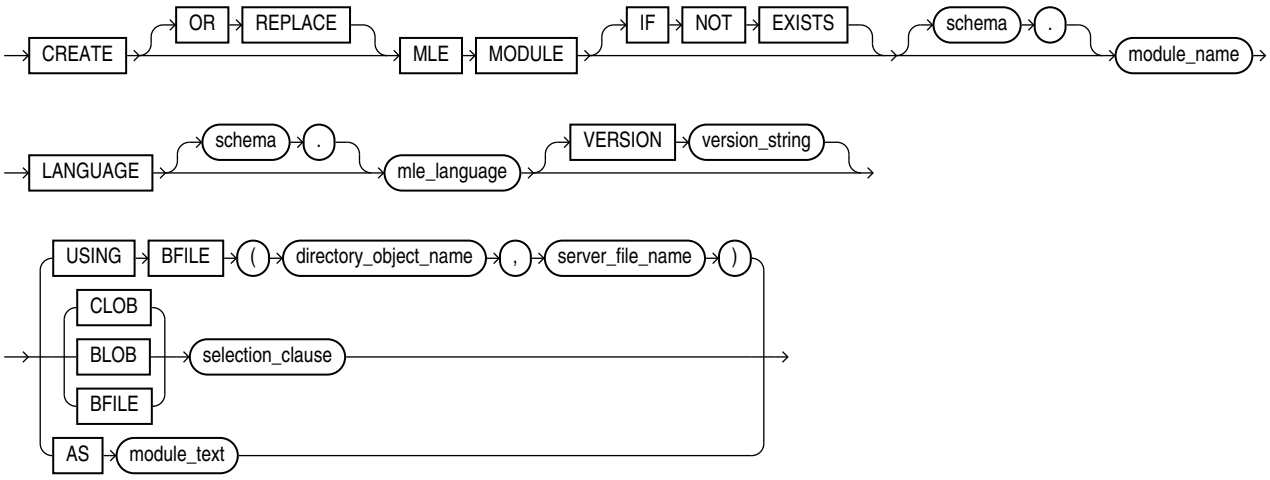
Purpose

Multilingual Engine (MLE) allows developers to write, store, and execute JavaScript code in Oracle Database Release 23 on Linux `x86-64` by using MLE Modules to encapsulate JavaScript.

Use `CREATE MLE MODULE` to create a new MLE module in the database.

> **See Also:**
>
> *JavaScript Developer's Guide*

Syntax



Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the module if it already exists. You can use this clause to change the definition of an existing module without dropping, re-creating, and regranting object privileges previously granted on it.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the MLE module does not exist, a new MLE module is created at the end of the statement.
- If the MLE module exists, this is the MLE module you have at the end of the statement. A new one is not created because the older one is detected.

You can have one of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

schema

Use *`schema`* to fully qualify the module name. If you do not specify *`schema`*, then the current schema is used.

The length of the module name must not exceed 128 bytes. MLE modules use the same namespace as tables and procedures.

LANGUAGE, VERSION

Use `LANGUAGE` to specify the MLE language of the created module. You must use the value `JAVASCRIPT` when you create JavaScript modules. An `ORA-04101` error is thrown if an unsupported MLE language is used.

The optional `VERSION` clause specifies a version string for the MLE module. Version strings are purely informational and do not influence any behavior of MLE or the RDBMS. The version string must fit into a `VARCHAR2(256)`.

CLOB, BLOB, BFILE

Use `USING` to create MLE modules from code contained in `CLOB`s, `BLOB`s, or `BFILE`s.

You can specify the `BFILE` clause with a subquery or with a directory using *`directory_object_name`* and *`server_file_name`* to specify the directory and filename of the MLE module you want to use. Note that you must create the directory object before this step using `CREATE DIRECTORY` .

The `CLOB | BLOB | BFILE` clause specifies a subquery whose result must be a single row and column of the specified type (`CLOB`, `BLOB`, or `BFILE`) that holds the contents of the MLE module to be deployed. The `CLOB` option is available only if the MLE module contains textual data. The textual data in MLE modules contained in `BLOB`s and `BFILE`s is encoded in `UTF-8`.

AS

Use `AS` to specify the contents of the MLE module as a sequence of characters inlined in the DDL statement. As with `CLOB`s, the `AS` clause is only available when the source of the MLE module contains textual data. Do not encapsulate the character sequence within quotes. The character sequence is delimited by the end of the DDL statement.

See Also:

- *JavaScript Developer's Guide*
- DROP MLE MODULE
- ALTER MLE MODULE
- CREATE MLE ENV

CREATE OPERATOR

Purpose

Use the `CREATE OPERATOR` statement to create a new operator and define its bindings.

Operators can be referenced by indextypes and by SQL queries and DML statements. The operators, in turn, reference functions, packages, types, and other user-defined objects.

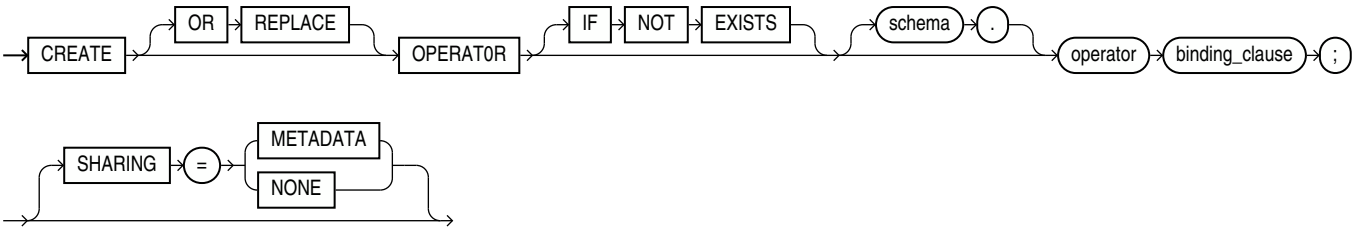
> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide* and *Oracle Database Concepts* for a discussion of these dependencies and of operators in general

Prerequisites

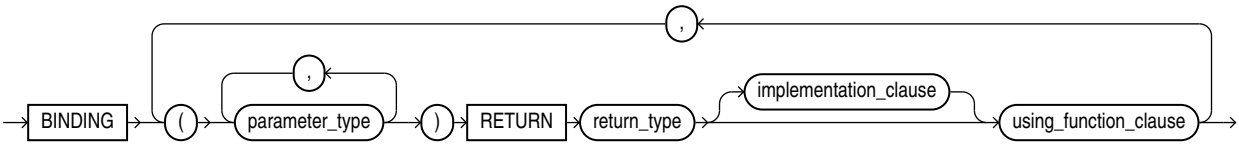
To create an operator in your own schema, you must have the `CREATE OPERATOR` system privilege. To create an operator in another schema, you must have the `CREATE ANY OPERATOR` system privilege. In either case, you must also have the `EXECUTE` object privilege on the functions and operators referenced.

Syntax

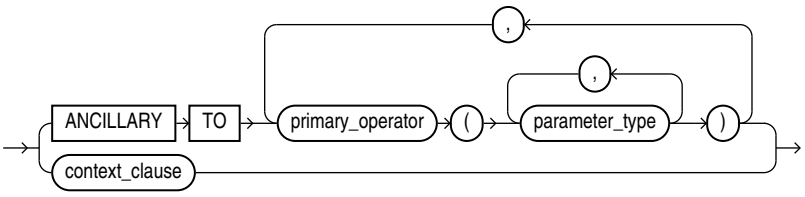
***create_operator*::=**



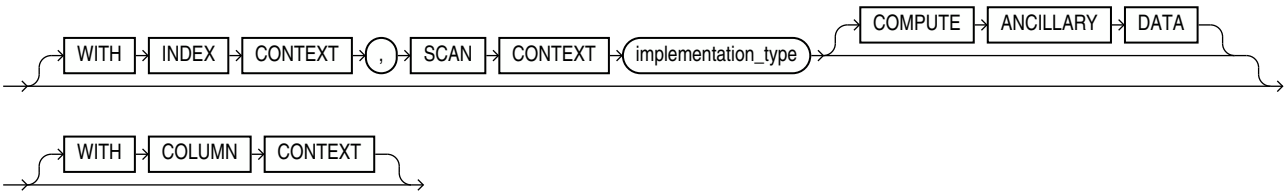
***binding_clause*::=**



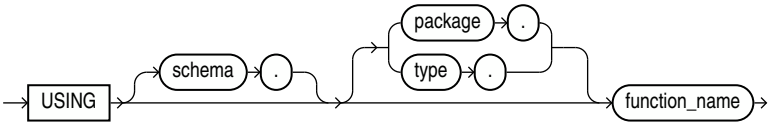
***implementation_clause*::=**



***context_clause*::=**



***using_function_clause*::=**



Semantics

OR REPLACE

Specify `OR REPLACE` to replace the definition of the operator schema object.

Restriction on Replacing an Operator

You can replace the definition only if the operator has no dependent objects, such as indextypes supporting the operator.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the operator does not exist, a new operator is created at the end of the statement.
- If the operator exists, this is the operator you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

schema

Specify the schema containing the operator. If you omit *`schema`*, then the database creates the operator in your own schema.

operator

Specify the name of the operator to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

binding_clause

Use the *binding_clause* to specify one or more parameter data types (*parameter_type*) for binding the operator to a function. The signature of each binding—the sequence of the data types of the arguments to the corresponding function—must be unique according to the rules of overloading.

The *parameter_type* can itself be an object type. If it is, then you can optionally qualify it with its schema.

Restriction on Binding Operators

You cannot specify a *parameter_type* of REF, LONG, or LONG RAW.

> **See Also:**
>
> *Oracle Database PL/SQL Language Reference* for more information about overloading

RETURN Clause

Specify the return data type for the binding.

The *return_type* can itself be an object type. If so, then you can optionally qualify it with its schema.

Restriction on Binding Return Data Type

You cannot specify a *return_type* of REF, LONG, or LONG RAW.

SHARING

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- METADATA - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- NONE - The object is not shared and can only be accessed in the application root.

implementation_clause

Use this clause to describe the implementation of the binding.

ANCILLARY TO Clause

Use the ANCILLARY TO clause to indicate that the operator binding is ancillary to the specified primary operator binding (*primary_operator*). If you specify this clause, then do not specify a previous binding with just one number parameter.

context_clause

Use the *context_clause* to describe the functional implementation of a binding that is not ancillary to a primary operator binding.

WITH INDEX CONTEXT, SCAN CONTEXT

Use this clause to indicate that the functional evaluation of the operator uses the index and a scan context that is specified by the implementation type.

COMPUTE ANCILLARY DATA

Specify `COMPUTE ANCILLARY DATA` to indicate that the operator binding computes ancillary data.

WITH COLUMN CONTEXT

Specify `WITH COLUMN CONTEXT` to indicate that Oracle Database should pass the column information to the functional implementation for the operator.

If you specify this clause, then the signature of the function implemented must include one extra `ODCIFuncCallInfo` structure.

> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide* for instructions on using the `ODCIFuncCallInfo` routine

using_function_clause

The *`using_function_clause`* lets you specify the function that provides the implementation for the binding. The *`function_name`* can be a standalone function, packaged function, type method, or a synonym for any of these.

If the function is subsequently dropped, then the database marks all dependent objects `INVALID`, including the operator. However, if you then subsequently issue an `ALTER OPERATOR ... DROP BINDING` statement to drop the binding, then subsequent queries and DML will revalidate the dependent objects.

Examples

Creating User-Defined Operators: Example

This example creates a very simple functional implementation of equality and then creates an operator that uses the function. For a more complete set of examples, see *Oracle Database Data Cartridge Developer's Guide*.

```
CREATE FUNCTION eq_f(a VARCHAR2, b VARCHAR2) RETURN NUMBER AS
BEGIN
   IF a = b THEN RETURN 1;
   ELSE RETURN 0;
   END IF;
END;
/

CREATE OPERATOR eq_op
   BINDING (VARCHAR2, VARCHAR2)
   RETURN NUMBER
   USING eq_f;
```

CREATE OUTLINE

Purpose

> **Note:**
>
> Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.
>
> You can migrate existing stored outlines to SQL plan baselines by using the `MIGRATE_STORED_OUTLINE` function of the `DBMS_SPM` package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the `DROP_MIGRATED_STORED_OUTLINE` function of the `DBMS_SPM` package.
>
> See Also: *Oracle Database SQL Tuning Guide* for more information about SQL plan management and *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_SPM` package

Use the `CREATE OUTLINE` statement to create a **stored outline**, which is a set of attributes used by the optimizer to generate an execution plan. You can then instruct the optimizer to use a set of outlines to influence the generation of execution plans whenever a particular SQL statement is issued, regardless of changes in factors that can affect optimization. You can also modify an outline so that it takes into account changes in these factors.

> **Note:**
>
> The SQL statement you want to affect must be an exact string match of the statement specified when creating the outline.

> **See Also:**
>
> - *Oracle Database SQL Tuning Guide* for information on execution plans
> - ALTER OUTLINE for information on modifying an outline
> - ALTER SESSION and ALTER SYSTEM for information on the `USE_STORED_OUTLINES` and `USE_PRIVATE_OUTLINES` parameters

Prerequisites

To create a public or private outline, you must have the `CREATE ANY OUTLINE` system privilege.

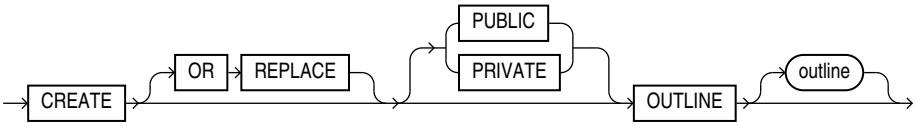
If you are creating a clone outline from a source outline, then you must also have the `SELECT_CATALOG_ROLE` role.

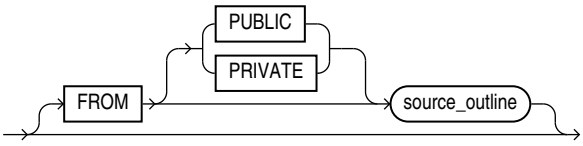
You can enable or disable the use of stored outlines dynamically for an individual session or for the system:

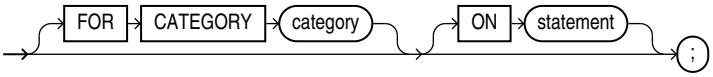
- Enable the `USE_STORED_OUTLINES` parameter to use public outlines.
- Enable the `USE_PRIVATE_OUTLINES` parameter to use private stored outlines.

Syntax

***create_outline*::=**







> **Note:**
>
> None of the clauses after *`outline`* are required. However, you must specify at least one clause after *`outline`*, and it must be either the `FROM` clause or the `ON` clause.

Semantics

OR REPLACE

Specify `OR REPLACE` to replace an existing outline with a new outline of the same name.

PUBLIC | PRIVATE

Specify `PUBLIC` if you are creating an outline for use by `PUBLIC`. This is the default.

Specify `PRIVATE` to create an outline for private use by the current session only. The data of this outline is stored in the current schema.

outline

Specify the unique name to be assigned to the stored outline. The name must satisfy the requirements listed in "Database Object Naming Rules ". If you do not specify *`outline`*, then the database generates an outline name.

> **See Also:**
>
> "Creating an Outline: Example"

FROM *source_outline* Clause

Use the `FROM` clause to create a new outline by copying an existing one. By default, Oracle Database looks for *`source_category`* in the public area. If you specify `PRIVATE`, then the database looks for the outline in the current schema.

Restriction on Copying an Outline

If you specify the `FROM` clause, then you cannot specify the `ON` clause.

> **See Also:**
>
> "Creating a Private Clone Outline: Example" and "Publicizing a Private Outline to the Public Area: Example"

FOR CATEGORY Clause

Specify an optional name used to group stored outlines. For example, you could specify a category of outlines for end-of-week use and another for end-of-quarter use. If you do not specify *`category`*, then the outline is stored in the `DEFAULT` category.

ON Clause

Specify the SQL statement for which the database will create an outline when the statement is compiled. This clause is optional only if you are creating a copy of an existing outline using the `FROM` clause.

You can specify any one of the following statements: `SELECT`, `DELETE`, `UPDATE`, `INSERT ... SELECT`, `CREATE TABLE ... AS SELECT`.

Restrictions on the ON Clause

This clause is subject to the following restrictions:

- If you specify the `ON` clause, then you cannot specify the `FROM` clause.
- You cannot create an outline on a multitable `INSERT` statement.
- The SQL statement in the `ON` clause cannot include any DML operation on a remote object.

> **Note:**
>
> In subsequent statements, you can specify additional outlines for the same SQL statement, but each outline for the same statement must specify a different category in the `CATEGORY` clause.

Examples

Creating an Outline: Example

The following statement creates a stored outline by compiling the `ON` statement. The outline is called `salaries` and is stored in the category `special`.

```
CREATE OUTLINE salaries FOR CATEGORY special
   ON SELECT last_name, salary FROM employees;
```

When this same `SELECT` statement is subsequently compiled, if the `USE_STORED_OUTLINES` parameter is set to `special`, the database generates the same execution plan as was generated when the outline `salaries` was created.

Creating a Private Clone Outline: Example

The following statement creates a stored private outline `my_salaries` based on the public category `salaries` created in the preceding example.

```
CREATE OR REPLACE PRIVATE OUTLINE my_salaries
   FROM salaries;
```

Publicizing a Private Outline to the Public Area: Example

The following statement copies back (publicizes) a private outline to the public area after private editing:

```
CREATE OR REPLACE OUTLINE public_salaries
   FROM PRIVATE my_salaries;
```

CREATE PACKAGE

Purpose

Packages are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `CREATE PACKAGE` statement to create the specification for a stored **package**, which is an encapsulated collection of related procedures, functions, and other program objects stored together in the database. The **package specification** declares these objects. The **package body**, specified subsequently, defines these objects.

> **See Also:**
>
> - CREATE PACKAGE BODY for information on specifying the implementation of the package
> - CREATE FUNCTION and CREATE PROCEDURE for information on creating standalone functions and procedures
> - ALTER PACKAGE and DROP PACKAGE for information on modifying and dropping a package
> - *Oracle Database Development Guide* and *Oracle Database PL/SQL Packages and Types Reference* for detailed discussions of packages and how to use them

Prerequisites

To create or replace a package in your own schema, you must have the `CREATE PROCEDURE` system privilege. To create or replace a package in another user's schema, you must have the `CREATE ANY PROCEDURE` system privilege.

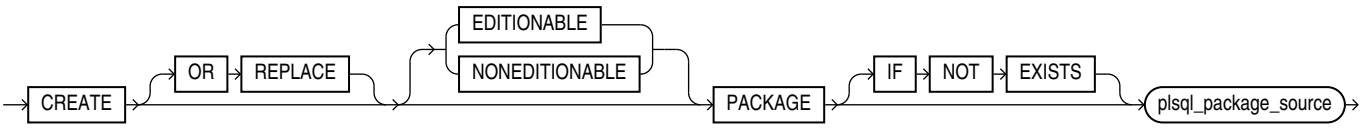
To embed a `CREATE PACKAGE` statement inside an Oracle Database precompiler program, you must terminate the statement with the keyword `END-EXEC` followed by the embedded SQL statement terminator for the specific language.

> **See Also:**
>
> *Oracle Database PL/SQL Language Reference* for more information

Syntax

Packages are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

***create_package*::=**



(*plsql_package_source*: See *Oracle Database PL/SQL Language Reference*.)

Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the package specification if it already exists. Use this clause to change the specification of an existing package without dropping, re-creating, and regranting object privileges previously granted on the package. If you change a package specification, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined package can still access the package without being regranted the privileges.

If any function-based indexes depend on the package, then the database marks the indexes `DISABLED`.

> **See Also:**
>
> `ALTER PACKAGE` for information on recompiling package specifications

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the package does not exist, a new package is created at the end of the statement.
- If the package exists, this is the package you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

[EDITIONABLE | NONEDITIONABLE]

Use these clauses to specify whether the package is an editioned or noneditioned object if editioning is enabled for the schema object type `PACKAGE` in *`schema`*. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

plsql_package_source

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the *`plsql_package_source`*, including examples.

CREATE PACKAGE BODY

Purpose

Package bodies are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `CREATE PACKAGE BODY` statement to create the body of a stored **package**, which is an encapsulated collection of related procedures, stored functions, and other program objects stored together in the database. The **package body** defines these objects. The **package specification**, defined in an earlier `CREATE PACKAGE` statement, declares these objects.

Packages are an alternative to creating procedures and functions as standalone schema objects.

See Also:

- CREATE FUNCTION and CREATE PROCEDURE for information on creating standalone functions and procedures
- CREATE PACKAGE for a discussion of packages, including how to create packages
- ALTER PACKAGE for information on modifying a package
- DROP PACKAGE for information on removing a package from the database

Prerequisites

To create or replace a package in your own schema, you must have the `CREATE PROCEDURE` system privilege. To create or replace a package in another user's schema, you must have the `CREATE ANY PROCEDURE` system privilege. In both cases, the package body must be created in the same schema as the package.

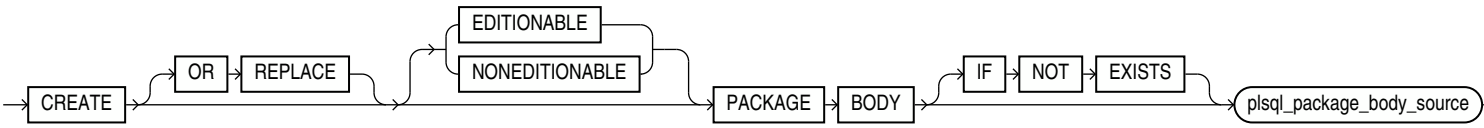
To embed a `CREATE PACKAGE BODY` statement inside an Oracle Database precompiler program, you must terminate the statement with the keyword `END-EXEC` followed by the embedded SQL statement terminator for the specific language.

> **See Also:**
>
> *Oracle Database PL/SQL Language Reference*

Syntax

Package bodies are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

***create_package_body*::=**



(*plsql_package_body_source*: See *Oracle Database PL/SQL Language Reference*.)

Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the package body if it already exists. Use this clause to change the body of an existing package without dropping, re-creating, and regranting object privileges previously granted on it. If you change a package body, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined package can still access the package without being regranted the privileges.

> **See Also:**
>
> ALTER PACKAGE for information on recompiling package bodies

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the package body does not exist, a new package body is created at the end of the statement.
- If the package body exists, this is the package body you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement`.

[EDITIONABLE | NONEDITIONABLE]

If you do not specify this clause, then the package body inherits `EDITIONABLE` or `NONEDITIONABLE` from the package specification. If you do specify this clause, then it must match that of the package specification.

plsql_package_body_source

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the *plsql_package_body_source*.

CREATE PFILE

Purpose

Use the `CREATE PFILE` statement to export either a binary server parameter file or the current In-Memory parameter settings into a text initialization parameter file. Creating a text parameter file is a convenient way to get a listing of the current parameter settings being used by the database, and it lets you edit the file easily in a text editor and then convert it back into a server parameter file using the `CREATE SPFILE` statement.

Upon successful execution of this statement, Oracle Database creates a text parameter file on the server. In an Oracle Real Application Clusters environment, it will contain all parameter settings of all instances. It will also contain any comments that appeared on the same line with a parameter setting in the server parameter file.

Note on Creating Text Parameter Files in a CDB

When you create a text parameter file in a multitenant container database (CDB), the current container can be the root or a PDB.

- If the current container is the root, then the database creates a text file that contains the parameter settings for the root.
- If the current container is a PDB, then the database creates a text file that contains the parameter settings for the PDB. In this case you must specify a *pfile_name*.

> **See Also:**
>
> - CREATE SPFILE for information on server parameter files
> - *Oracle Database Administrator's Guide* for additional information on text initialization parameter files and binary server parameter files
> - *Oracle Real Application Clusters Administration and Deployment Guide* for information on using server parameter files in an Oracle Real Application Clusters environment

Prerequisites

You must have one of the following system privileges to execute this statement:

- `SYSDBA`

- SYSDG
- SYSOPER
- SYSBACKUP
- SYSASM
- SYSRAC

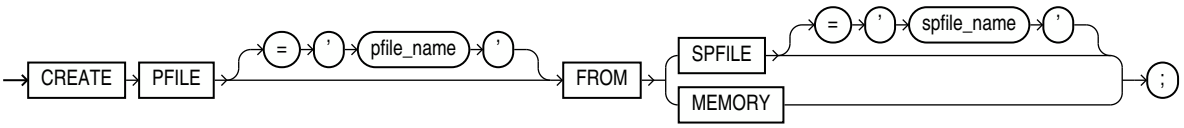
You can execute this statement either before or after instance startup.

Restrictions

You cannot overwrite OS files as a SYSDG, SYSOPER, or SYSRAC user.

Syntax

***create_pfile*::=**



Semantics

pfile_name

Specify the name of the text parameter file you want to create. If you do not specify *pfile_name*, then Oracle Database uses the platform-specific default initialization parameter file name. *pfile_name* can include a path prefix. If you do not specify such a path prefix, then the database adds the path prefix for the default storage location, which is platform dependent.

spfile_name

Specify the name of the binary server parameter from which you want to create a text file.

- If you specify *spfile_name*, then the file must exist on the server. If the file does not reside in the default directory for server parameter files on your operating system, then you must specify the full path.
- If you do not specify *spfile_name*, then the database uses the spfile that is currently associated with the instance, usually the one that was used a startup. If no spfile is associated with the instance, then the database looks for the platform-specific default server parameter file name. If that file does not exist, then the database returns an error.

> **See Also:**
>
> Creating and Configuring an Oracle Database

MEMORY

Specify MEMORY to create a pfile using the current system-wide parameter settings. In an Oracle RAC environment, the created file will contain the parameter settings from each instance.

Examples

Creating a Parameter File: Example

The following example creates a text parameter file `my_init.ora` from a binary server parameter file `s_params.ora`:

```
CREATE PFILE = 'my_init.ora' FROM SPFILE = 's_params.ora';
```

> **Note:**
>
> Typically you will need to specify the full path and filename for parameter files on your operating system. Refer to your Oracle operating system documentation for path information and default parameter file names.

CREATE PLUGGABLE DATABASE

Purpose

Use the `CREATE PLUGGABLE DATABASE` statement to create a pluggable database (PDB).

This statement enables you to perform the following tasks:

- Create a PDB by using the seed as a template

  Use the *`create_pdb_from_seed`* clause to create a PDB by using the seed in the multitenant container database (CDB) as a template. The files associated with the seed are copied to a new location and the copied files are then associated with the new PDB.
- Create a PDB by cloning an existing PDB

  Use the *`create_pdb_clone`* clause to create a PDB by copying an existing PDB and then plugging the copy into the CDB. The files associated with the existing PDB are copied to a new location and the copied files are associated with the new PDB.
- Create a PDB by plugging an unplugged PDB into a CDB

  Use the *`create_pdb_from_xml`* clause to plug an unplugged PDB into a CDB, using an XML metadata file.
- Create a proxy PDB by referencing another PDB. A proxy PDB provides fully functional access to the referenced PDB.

  Use the *`create_pdb_clone`* clause and specify `AS PROXY FROM` to create a proxy PDB.
- Create an application container, application seed, or application PDB

  Use the *`create_pdb_from_seed`*, *`create_pdb_clone`*, or *`create_pdb_from_xml clause`*. To create an application container, you must specify the `AS APPLICATION CONTAINER` clause. To create an application seed, you must specify the `AS SEED` clause.

> **Note:**
>
> A multitenant container database is the only supported architecture in Oracle Database 21c and later releases. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

> **Note:**
>
> When a new PDB is established in a CDB, it is possible that the name of a service offered by the new PDB will collide with an existing service name. The namespace in which a collision can occur is that of the listener that gives access to the CDB. Within that namespace, collisions are possible among the names of CDB's default services, PDB's default services, and user-defined services. For example, if two or more CDBs on the same computer system use the same listener, and the newly established PDB has the same service name as another PDB in these CDBs, then a collision occurs.
>
> When you create a PDB, you can specify new names for any potential colliding service names. See the clause *service_name_convert*. If you discover a service name collision after a PDB is created, you must not attempt to operate the PDB that causes a collision with an existing service name. If the colliding name is that of the PDB's default service, then you must rename the PDB. If the colliding name is that of a user-created service within the PDB, then you must drop that service and create one in its place, with a non-colliding name, that has the same purpose and properties.

> **See Also:**
>
> - *Oracle Multitenant Administrator's Guide* for more information on multi-tenant architecture and concepts.
> - ALTER PLUGGABLE DATABASE and DROP PLUGGABLE DATABASE for information on modifying and dropping PDBs

Prerequisites

You must be connected to a CDB. The CDB must be open and in `READ WRITE` mode.

To create a PDB or an application container, the current container must be the root and you must have the `CREATE PLUGGABLE DATABASE` system privilege, granted commonly.

To create an application seed or an application PDB, the current container must be an application root, the application container must be open and in `READ WRITE` mode, and you must have the `CREATE PLUGGABLE DATABASE` system privilege, either granted commonly or granted locally in that application container.

To specify the *`create_pdb_clone`* clause:

- If *src_pdb_name* refers to a PDB in the same CDB, then you must have the CREATE PLUGGABLE DATABASE system privilege in the root of the CDB in which the new PDB will be created and in the PDB being cloned.
- If *src_pdb_name* refers to a PDB in a remote database, then you must have the CREATE PLUGGABLE DATABASE system privilege in the root of the CDB in which the new PDB will be created. In addition, the remote user must have the CREATE PLUGGABLE DATABASE system privilege in the PDB to which *src_pdb_name* refers.

See *Oracle Multitenant Administrator's Guide* for more information on the prerequisites to PDB creation.

Semantics

pdb_name

Specify the name of the PDB to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ". The first character of a PDB name must be an alphabet character. The remaining characters can be alphanumeric or the underscore character (_).

The PDB name must be unique in the CDB, and it must be unique within the scope of all the CDBs whose instances are reached through a specific listener.

AS APPLICATION CONTAINER

Specify this clause to create an application container.

> **See Also:**
>
> Creating and Removing Application Containers and Seeds

using_snapshot_clause

Specify this clause to create a PDB from an existing PDB snapshot that can be identified by its name, SCN, or timestamp.

If you additionally specify SNAPSHOT COPY, then the new PDB will depend on the existence of the specified PDB snapshot. This will affect your ability to drop or purge the new PDB.

AS SEED

Specify this clause to create an application seed. The database assigns the seed a name of the form *application_container_name*`$SEED`.

An application container can have at most one application seed. The application seed is optional, but, if it exists, you can use it to create application PDBs quickly that match the requirements of the application container. An application seed enables instant provisioning of application PDBs that are created from it.

> **See Also:**
>
> Creating and Removing Application Containers and Seeds

create_pdb_from_seed

This clause enables you to create a PDB by using the seed in the CDB as a template.

> **See Also:**
>
> Creating a PDB from Scratch

ADMIN USER

Use this clause to create an administrative user who can be granted the privileges required to perform administrative tasks on the PDB. For *admin_user_name*, specify name of the user to be created. Use the `IDENTIFIED BY` clause to specify the password for *admin_user_name*. Oracle Database creates a local user in the PDB and grants the `PDB_DBA` local role to that user.

pdb_dba_roles

This clause lets you grant one or more roles to the PDB_DBA role. Use this clause to grant roles that have the privileges required by the administrative user of the PDB. For *role*, specify a predefined role. For a list of predefined roles, refer to *Oracle Database Security Guide*.

You can also use the GRANT statement to grant roles to the PDB_DBA role after the PDB has been created. Until you have granted the appropriate privileges to the PDB_DBA role, the SYS and SYSTEM users can perform administrative tasks on a PDB.

parallel_pdb_creation_clause

This clause instructs the CDB to use parallel execution servers to copy the new PDB's data files to a new location. This may result in faster creation of the PDB.

PARALLEL

If you specify PARALLEL, then the CDB automatically chooses the number of parallel execution servers to use. This is the default if the COMPATIBLE initialization parameter is set to 12.2 or higher.

PARALLEL *integer*

Use integer to specify the number of parallel execution servers to use. The CDB can ignore this setting, depending on the current database load and the number of available parallel execution servers. If you specify a value of 0 or 1, then the CDB does not parallelize the creation of the PDB. This can result in a longer PDB creation time.

default_tablespace

If you specify this clause, then Oracle Database creates a smallfile tablespace and sets it as the default permanent tablespace for the PDB. Oracle Database will assign the default tablespace to any non-SYSTEM user for whom a different permanent tablespace is not specified. The *default_tablespace* clause has the same semantics that it has for the CREATE DATABASE statement. For full information, refer to *default_tablespace* in the documentation on CREATE DATABASE.

pdb_storage_clause

Use this clause to specify storage limits for the PDB.

- Use MAXSIZE to limit the amount of storage that can be used by all tablespaces in the PDB to the value specified with *size_clause*. This limit includes the size of data files and temporary files for tablespaces belonging to the PDB. Specify MAXSIZE UNLIMITED to enforce no limit.
- Use MAX_AUDIT_SIZE to limit the amount of storage that can be used by unified audit OS spillover (.bin format) files in the PDB to the value specified with *size_clause*. Specify MAX_AUDIT_SIZE UNLIMITED to enforce no limit.
- Use MAX_DIAG_SIZE to limit the amount of storage for diagnostics (trace files and incident dumps) in the Automatic Diagnostic Repository (ADR) that can be used by the PDB to the value specified with *size_clause*. Specify MAX_DIAG_SIZE UNLIMITED to enforce no limit.

If you omit this clause, or specify STORAGE UNLIMITED, then there are no storage limits for the PDB. This is equivalent to specifying STORAGE (MAXSIZE UNLIMITED MAX_AUDIT_SIZE UNLIMITED MAX_DIAG_SIZE UNLIMITED).

file_name_convert

Use this clause to determine how the database generates the names of files (such as data files and wallet files) for the PDB.

- For *filename_pattern*, specify a string found in names of files associated with the seed (when creating a PDB by using the seed), associated with the source PDB (when cloning a PDB), or listed in the XML file (when plugging a PDB into a CDB).
- For *replacement_filename_pattern*, specify a replacement string.

Oracle Database will replace *filename_pattern* with *replacement_filename_pattern* when generating the names of files associated with the new PDB.

File name patterns cannot match files or directories managed by Oracle Managed Files.

You can specify `FILE_NAME_CONVERT = NONE`, which is the same as omitting this clause. If you omit this clause, then the database first attempts to use Oracle Managed Files to generate file names. If you are not using Oracle Managed Files, then the database uses the `PDB_FILE_NAME_CONVERT` initialization parameter to generate file names. If this parameter is not set, then an error occurs.

service_name_convert

Use this clause to rename the user-defined services of the new PDB based on the service names of the source PDB. When the service name of a new PDB conflicts with an existing service name in the CDB, plug-in violations can result. This clause enables you to avoid these violations.

- For *service_name*, specify the name of a service found in the PDB seed (when creating a PDB in an application container by using the application seed) or in the source PDB (when cloning a PDB or plugging a PDB into a CDB).
- For *replacement_service_name*, specify the replacement name for the service.

Oracle Database will use the replacement service name for the service in the PDB being created.

You can specify `SERVICE_NAME_CONVERT = NONE`, which is the same as omitting this clause.

Restrictions on *service_name_convert*

The *service_name_convert* clause is subject to the following restrictions:

- You cannot change the name of the default service for a PDB. The default service has the same name as the PDB.
- You cannot specify this clause when you use the *create_pdb_from_seed* clause to create a PDB from the CDB seed, because the CDB seed does not have user-defined services. You can, however, specify this clause when you use the *create_pdb_from_seed* clause to create an application PDB from the application seed.

path_prefix_clause

Use this clause to ensure that file paths for directory objects associated with the PDB are restricted to the specified directory or its subdirectories. This clause also ensures that the following files associated with the PDB are restricted to the specified directory: the Oracle XML repository for the PDB, files created with a `CREATE PFILE` statement, and the export directory for Oracle wallets. You cannot modify the setting of this clause after you create the PDB. This clause does not affect files created by Oracle Managed Files.

- For *path_name*, specify the absolute path name of an operating system directory. The single quotation marks are required, with the result that the path name is case sensitive. Oracle Database uses *path_name* as a prefix for all file paths associated with the PDB.

  Be sure to specify *path_name* so that the resulting path name will be properly formed when relative paths are appended to it. For example, on UNIX systems, be sure to end *path_name* with a forward slash (/), such as:

  ```
  PATH_PREFIX = '/disk1/oracle/dba/salespdb/'
  ```

- For *directory_object_name*, specify the name of a directory object that exists in the CDB root (CDB$ROOT). The directory object points to the absolute path to be used for PATH_PREFIX.
- If you specify PATH_PREFIX = NONE, then the relative paths for directory objects associated with the PDB are treated as absolute paths and are not restricted to a particular directory.

Omitting the *path_prefix_clause* is equivalent to specifying PATH_PREFIX = NONE.

After the *path_prefix_clause* is specified for a PDB, existing directory objects might not work as expected, since the PATH_PREFIX string is always added as a prefix to all local directory objects in the PDB. The *path_prefix_clause* only applies to user-created directory objects. It does not apply to Oracle-supplied directory objects.

tempfile_reuse_clause

When you create a PDB, Oracle Database associates temp files with the new PDB. Depending on how you create the PDB, the temp files may already exist and may have been previously used.

Specify TEMPFILE REUSE to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. If you specify this clause and a temp file does not exist, then the database creates the temp file.

If you do not specify TEMPFILE REUSE and a temp file to be associated with the new PDB already exists, then the database returns an error and does not create the PDB.

user_tablespaces_clause

This clause lets you specify the tablespaces to be made available in the new PDB. The SYSTEM, SYSAUX, and TEMP tablespaces are available in all PDBs and cannot be specified in this clause.

You can use this clause to separate the data for multiple schemas into different PDBs.

- Specify *tablespace* to make the tablespace available in the new PDB. You can specify more than one tablespace in a comma-separated list.
- Specify ALL to make all tablespaces available in the new PDB. This is the default.
- Specify ALL EXCEPT to make all tablespaces available in the new PDB, except the specified tablespaces.
- Specify NONE to make only the SYSTEM, SYSAUX, and TEMP tablespaces available in the new PDB.

When the compatibility level of the CDB is 12.2 or higher, the tablespaces that are excluded by this clause are created offline in the new PDB, and they have no data files associated with them. When the compatibility level of the CDB is lower than 12.2, the tablespaces that are excluded by this clause are offline in the new PDB, and all data files that belong to these tablespaces are unnamed and offline.

{ SNAPSHOT COPY | NO DATA }

These clauses apply only when cloning a PDB with the *create_pdb_clone* clause. By default, the database creates each tablespace to be made available in the new PDB according to the settings specified for cloning the PDB. These clauses allow you to override those settings as follows:

- SNAPSHOT COPY - Clone the tablespace using storage snapshots.
- NO DATA - Clone the data model definition of the tablespace, but not the tablespace's data.

{ COPY | MOVE | NOCOPY }

These clauses apply when you plug in a PDB with the *create_pdb_from_xml* clause. By default, the database creates each tablespace to be made available in the new PDB according to the settings specified for plugging in the PDB. These clauses allow you to override those settings as follows:

- COPY - Copy the tablespace files to the new location.
- MOVE - Move the tablespace files to the new location.
- NOCOPY - Do not copy or move the tablespace files to the new location.

standbys_clause

Use this clause to specify whether the new PDB is included in one or more standby CDBs. If you include a PDB in a standby CDB, then during standby recovery the standby CDB will search for the data files for the PDB. If the data files are not found, then standby recovery will stop and you must copy the data files to the correct location before you can restart recovery.

- Specify *cdb_name* to include the new PDB in the specified standby CDB. You can specify more than one standby CDB name in a comma-separated list.
- Specify ALL to include the new PDB in all standby CDBs. This is the default.
- Specify ALL EXCEPT to include the new PDB in all standby CDBs, except the specified standby CDBs.
- Specify NONE to exclude the new PDB from all standby CDBs. When a PDB is excluded from all standby CDBs, the PDB's data files are unnamed and marked offline on all of the standby CDBs. Standby recovery will not stop if the data files for the PDB are not found on the standby. If you instantiate a new standby CDB after the PDB is created, then you must explicitly disable the PDB for recovery on the new standby CDB.

You can enable a PDB on a standby CDB after it was excluded on that standby CDB by copying the data files to the correct location, bringing the PDB online, and marking it as enabled for recovery.

logging_clause

Use this clause to specify the default logging attribute for tablespaces created within the PDB. The logging attribute controls whether certain DML operations are logged in the redo log file (LOGGING) or not (NOLOGGING).The default is LOGGING.

When creating a tablespace, you can override the default logging attribute by specifying the *logging_clause* of the CREATE TABLESPACE statement.

Refer to *logging_clause* for a full description of this clause.

create_file_dest_clause

By default, a newly created PDB inherits its Oracle Managed Files settings from the root. If the root uses Oracle Managed Files, then the PDB also uses Oracle Managed Files. The PDB shares the same base file system directory for Oracle Managed Files with the root and has its own subdirectory named with the GUID of the PDB. If the root does not use Oracle Managed Files, then the PDB also does not use Oracle Managed Files.

This clause lets you override the default behavior. You can enable or disable Oracle Managed Files for the PDB and you specify a different base file system directory or Oracle ASM disk group for the PDB's files.

- Specify `NONE` to disable Oracle Managed Files for the PDB.
- Specify either *`directory_path_name`* or *`diskgroup_name`* to enable Oracle Managed Files for the PDB.

  Specify *`directory_path_name`* to designate the base file system directory for the PDB's files. Specify the full path name of the operating system directory. The directory must exist and Oracle processes must have appropriate permissions on the directory. The single quotation marks are required, with the result that the path name is case sensitive.

  Specify *`diskgroup_name`* to designate the default Oracle ASM disk group for the PDB's files.

If you specify a value other than `NONE`, then the database implicitly sets the `DB_CREATE_FILE_DEST` initialization parameter with `SCOPE=SPFILE` in the PDB.

HOST and PORT

These clauses are useful only if you are creating a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB.

When creating a referenced PDB:

- If the name of the listener is different from the host name of the PDB, then you must specify the `HOST` clause. For *`hostname`*, specify the fully qualified domain name of the listener. Enclose *`hostname`* in single quotation marks. For example: `'myhost.example.com'`.

  In an Oracle Real Application Clusters (Oracle RAC) environment, you can specify for *`hostname`* any of the hosts for the PDB.
- If the port number of the listener is not 1521, then you must specify the `PORT` clause. For *`number`*, specify the port number for the listener.

A proxy PDB uses a database link to establish communication with its referenced PDB. After communication is established, the proxy PDB communicates directly with the referenced PDB without using a database link. The host name and port number of the listener for the referenced PDB must be correct for the proxy PDB to function properly.

> **See Also:**
>
> The clause AS PROXY FROM of *`create_pdb_clone`* for information on creating a proxy PDB

create_pdb_clone

This clause enables you to create a new PDB by cloning a source to a target PDB. The source can be a PDB in the local CDB, or a PDB in a remote CDB. The target PDB is the clone of the source.

If the source is a PDB in the local CDB, then the source PDB can be plugged in or unplugged. If the source is a PDB in a remote CDB, then the source PDB must be plugged in.

If the source is a PDB in a remote CDB, then the source and the CDB that contains the target PDB must meet the following requirements:

- They must have the same endian format.
- They must have compatible character sets and national character sets, which means:
  - Every character in the source character set is available in the local CDB character set.
  - Every character in the source character set has the same code point value in the local CDB character set.
- They must have the same set of database options installed.

Users in the PDB who used the default temporary tablespace of the source PDB use the default temporary tablespace of the new PDB. Users who used non-default temporary tablespaces in the PDB continue to use the same local temporary tablespaces in the new PDB.

You can clone a united PDB or an isolated PDB with the same command. The only difference is that the keystore password you must provide are for different keystores.

Hot Clone a PDB: Example

```
CREATE PLUGGABLE DATABASE CDB1_PDB2_CLONE FROM CDB1_PDB2
 KEYSTORE IDENTIFIED BY keystore_password
```

For a **united** PDB:

- `keystore_password` is the `ROOT` keystore password.
- The wallet must be open in `ROOT`.

For an **isolated** PDB:

- `keystore_password` is the **new** keystore password for the PDB `CDB1_PDB2_CLONE`.
- The wallet must be open in `CDB1_PDB2_CLONE`.

Clone a PDB: Example

United PDB

```
CREATE PLUGGABLE DATABASE CDB1_PDB1_C AS CLONE USING '/tmp/cdb1_pdb3.pdb'
 KEYSTORE IDENTIFED BY keystore_password DECRYPT USING transport_secret
```

- The wallet must be open in `ROOT`, if TDE is in use.
- If there are TDE keys in the `.pdb` file, you must specify `KEYSTORE IDENTIFED BY` and provide *`transport_secret`*.
- *`keystore_password`* is the `ROOT` keystore password.

Isolated PDB

```
CREATE PLUGGABLE DATABASE CDB1_PDB2_C AS CLONE USING '/tmp/cdb1_pdb2.pdb'
```

- You need not specify `KEYSTORE IDENTIFED BY` or *`transport_secret`*. If specified, they are ignored.
- The wallet need *not* be open in `ROOT`.

> Cloning a PDB

FROM

Use this clause to specify the source PDB. The files associated with the source are copied to a new location and these copied files are then associated with the new PDB.

The source PDB cannot be closed. It can be open as follows:

- If the CDB that contains the source PDB (the source CDB) is in `ARCHIVELOG` mode and local undo mode, then the source PDB can be open in `READ WRITE` mode and fully functional during the cloning operation. This is called hot PDB cloning.
- If the source CDB is not in `ARCHIVELOG` mode, then the source PDB must be open `READ ONLY`.

Specify the source PDBas follows:

- If the source is a PDB in the local CDB, then use *`src_pdb_name`* to specify the name of the source PDB. You cannot specify `PDB$SEED` for *`src_pdb_name`*. Instead, use the *create_pdb_from_seed* clause to create a PDB by using the seed as a template.
- If the source is a PDB in a remote CDB, then use *`src_pdb_name`* to specify the name of the source PDB and *`dblink`* to specify the name of the database link to use to connect to the remote CDB.

AS PROXY FROM

Use this clause to create a proxy PDB by referencing a different PDB, which is referred to as the referenced PDB. The referenced PDB can be in the same CDB as the proxy PDB or in a different CDB. A local proxy PDB is in the same CDB as its referenced PDB, and a remote proxy PDB is in a different CDB than its referenced PDB.

For *`src_pdb_name@dblink`*, specify the referenced PDB.

> **See Also:**
>
> Creating a PDB as a Proxy PDB

default_tablespace

Use this clause to specify a permanent default tablespace for the PDB. Oracle Database will assign the default tablespace to any non-`SYSTEM` user for whom a different permanent tablespace is not specified. The tablespace must already exist in the source PDB. Because the tablespace already exists, you cannot specify the `DATAFILE` clause or the *`extent_management_clause`* when creating a PDB with the *`create_pdb_clone`* clause.

pdb_storage_clause

Use this clause to specify storage limits for the new PDB. Refer to *pdb_storage_clause* for the full semantics of this clause.

file_name_convert

Use this clause to determine how the database generates the names of files for the new PDB. Refer to *file_name_convert* for the full semantics of this clause.

service_name_convert

Use this clause to determine how the database renames services for the new PDB. Refer to *service_name_convert*::= for the full semantics of this clause.

path_prefix_clause

Use this clause to ensure that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. Refer to *path_prefix_clause* for the full semantics of this clause.

tempfile_reuse_clause

Specify `TEMPFILE REUSE` to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. Refer to *tempfile_reuse_clause* for the full semantics of this clause.

SNAPSHOT COPY

You can specify `SNAPSHOT COPY` only when cloning a PDB. The source PDB can be in the local CDB or a remote CDB. The `SNAPSHOT COPY` clause instructs the database to clone the source PDB using storage snapshots. This reduces the time required to create the clone because the database does not need to make a complete copy of the source data files.

When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB and the `CLONEDB` initialization parameter is set to `FALSE`, the underlying file system for the source PDB's files must support storage snapshots. Such file systems include Oracle Advanced Cluster File System (Oracle ACFS) and Direct NFS Client storage.

When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB and the `CLONEDB` initialization parameter is set to `TRUE`, the underlying file system for the source PDB's files can be any local file system, network file system (NFS), or clustered file system that has Direct NFS enabled. However, the source PDB must remain in open read-only mode as long as any clones exist.

Direct NFS Client enables an Oracle database to access network attached storage (NAS) devices directly, rather than using the operating system kernel NFS client. If the PDB files are stored on Direct NFS Client storage, then the following additional requirements must be met:

- The source PDB files must be located on an NFS volume.
- Storage credentials must be stored in a Transparent Data Encryption keystore.
- The storage user must have the privileges required to create and destroy snapshots on the volume that hosts the source PDB files.
- Credentials must be stored in the keystore using an `ADMINISTER KEY MANAGEMENT ADD SECRET` SQL statement.

When you use the SNAPSHOT COPY clause to create a clone of a source PDB, the following restrictions apply to the source PDB as long as any clones exist:

- It cannot be unplugged.
- It cannot be dropped.

PDB clones created using the SNAPSHOT COPY clause cannot be unplugged. They can only be dropped. Attempting to unplug a clone created using the SNAPSHOT COPY clause results in an error.

For a PDB created using the SNAPSHOT COPY clause in an Oracle Real Application Clusters (Oracle RAC) environment, each node that must access the PDB's files must be mounted. For Oracle RAC databases running on Linux or UNIX platforms, the underlying NFS volumes must be mounted. If the Oracle RAC database is running on a Windows platform and using Direct NFS for shared storage, then you must update the oranfstab file on all nodes with the created volume export and mount entries.

Storage clones are named and tagged using the new PDB GUID. You can query the CLONETAG column of DBA_PDB_HISTORY view to view clone tags for storage clones.

keystore_clause

Specify this clause if the source database has encrypted data or a keystore set.

If you want to create the PDB by cloning another PDB, and if the source database has encrypted data or a TDE master encryption key that has been set, then you must provide the keystore password of the target keystore in *keystore_password* .

You can find if the source database has encrypted data by querying the DBA_ENCRYPTED_COLUMNS data dictionary view or the V$ENCRYPTED_TABLESPACES dynamic performance view.

You can use the EXTERNAL STORE clause instead of *keystore_password* to clone a PDB that is using a united keystore. Note that you must configure the TDE SEPS wallet first before you use this option.

You cannot use the EXTERNAL STORE clause for a PDB that is using an isolated keystore.

You can set the password to a maximum length of 1024 bytes.

pdb_refresh_mode_clause

The REFRESH MODE clause applies only when cloning a PDB. The source PDB must be in a remote CDB, that is, you must specify the source PDB using the FROM *src_pdb_name@dblink* clause.

This clause lets you specify the refresh mode of the PDB. You can use this clause to create a **refreshable PDB**. Changes in the source PDB can be propagated to the refreshable PDB, either manually or automatically. This operation is called a refresh. You can specify the following refresh modes:

- MANUAL - This mode allows you to refresh the refreshable PDB manually at any time by issuing an ALTER PLUGGABLE DATABASE REFRESH statement.
- EVERY *refresh_interval* MINUTES or HOURS – This mode instructs the database to refresh the refreshable PDB every *refresh_interval* of selected time units, minutes or hours. If you select MINUTES, the refresh_interval must be less than 3000. If you select HOURS, the refresh_interval must be less than 2000. This mode also allows you to refresh the PDB manually at any time by issuing an ALTER PLUGGABLE DATABASE REFRESH statement.

- `NONE` - If you specify this mode, then the clone PDB is not a refreshable PDB. The database cannot refresh the PDB automatically and you cannot refresh the PDB manually. If you specify this mode, then you cannot later change the PDB into a refreshable PDB. This is the default.

A refreshable PDB can be opened only in `READ ONLY` mode. A refreshable PDB must be closed in order for a refresh to occur. If it is not closed when you attempt to perform a manual refresh, then an error will occur. If it is not closed when the database attempts an automatic refresh, then the refresh will be deferred until the next scheduled refresh.

> **See Also:**
>
> - `ALTER PLUGGABLE DATABASE` REFRESH for information on refreshing a PDB manually
> - `ALTER PLUGGABLE DATABASE` *pdb_refresh_mode_clause* for information on changing the refresh mode of a PDB
> - *Oracle Database Administrator's Guide* for more information on refreshable PDBs

RELOCATE

Use this clause to relocate a PDB from one CDB to another. The database first clones the source PDB to the target PDB, and then removes the source PDB. The database also moves the files associated with the PDB to a new location. This operation is the fastest way to relocate a PDB with minimal down time. The down time for the PDB is approximately the time required to copy the PDB's files from their old location to their new location. The source PDB can be open in `READ WRITE` mode and fully functional during the relocation operation.

Specify `REFRESH MODE` to keep the PDB current during the relocate process.

You can specify the availability level with the `AVAILABILITY` keyword. The default availability is `NORMAL`. If you specify `AVAILABILITY MAX`, then additional operations are performed to ensure a smooth migration of the workload in a persistent connection between source and target.

In the *create_pdb_clone* clause, you must use the `FROM` *src_pdb_name@dblink* syntax to identify the location of the source PDB. For *src_pdb_name*, specify the name of the source PDB. For *dblink*, specify a database link that indicates the location of the source PDB. The database link must have been created in the CDB to which the PDB will be relocated. It can connect either to the root of the remote CDB or to the remote PDB.

KEEP SOURCE

Specify `KEEP SOURCE` if you want to keep the source PDB and preserve it in an unplugged state.

> **See Also:**
>
> Relocating a PDB

NO DATA

The `NO DATA` clause applies only when cloning a PDB. This clause specifies that the source PDB's data model definition is cloned, but not the PDB's data. The dictionary data in the source PDB is cloned, but all user-created table and index data from the source PDB is discarded.

Restrictions on the NO DATA Clause

The following restrictions apply to the `NO DATA` clause:

- The source PDB should be open in read only mode when you use the `NO DATA` clause to clone a PDB.
- You cannot specify `NO DATA` if the source PDB contains clustered tables, Advanced Queuing (AQ) tables, index-organized tables, or tables that contain abstract data type columns.

HOST and PORT

These clauses are useful only if you are creating a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB. Refer to HOST and PORT for the full semantics of these clauses.

create_pdb_from_xml

This clause enables you to create a PDB by plugging an unplugged PDB (the source database) into a CDB (the target CDB). If the source database is an unplugged PDB, then it may have been unplugged from the target CDB or a different CDB.

The source database and the target CDB must meet the following requirements:

- They must have the same endian format.
- They must have compatible character sets and national character sets, which means:
  - Every character in the source database character set is available in the target CDB character set.
  - Every character in the source database character set has the same code point value in the target CDB character set.
- They must have the same set of database options installed.

> **See Also:**
>
> - Plugging In an Unplugged PDB
> - *Oracle Database PL/SQL Packages and Types Reference* for more information on the `DBMS_PDB` package

AS CLONE

Specify this clause only if the target CDB already contains a PDB that was created using the same set of data files. The source files remain as an unplugged PDB and can be used again. Specifying `AS CLONE` also ensures that Oracle Database generates new identifiers, such as DBID and GUID, for the new PDB.

USING

This clause lets you specify a file that contains information about the source database that your are plugging in. For *filename*, specify the full path name of the file. You can obtain this file in one of the following ways:

- If the source database is an unplugged PDB, then the file was created by the *pdb_unplug_clause* of ALTER PLUGGABLE DATABASE as follows:
  - If the filename ends with the extension .xml, then it is an XML file containing metadata about the PDB. In this case, you must ensure that the XML metadata file, as well as the PDB's data files, are in a location that is accessible to the CDB.
  - If the filename ends with the extension .pdb, then it is a PDB archive file. This is a compressed file that includes an XML file containing metadata about the PDB, as well as the PDB's data files. The PDB archive file must exist in a location that is accessible to the CDB. When you use a .pdb archive file, this file is extracted when you plug in the PDB, and the PDB's files are placed in the same directory as the .pdb archive file. Therefore, the *source_file_directory* clause is not required.
- If the source database is a non-CDB, then you must create the XML metadata file using the DBMS_PDB package, and ensure that the XML metadata file, as well as the source non-CDB's data files, are in a location that is accessible to the CDB.

> **See Also:**
>
> - *pdb_unplug_clause* of ALTER PLUGGABLE DATABASE
> - *Oracle Database PL/SQL Packages and Types Reference* for more information on the DBMS_PDB package

source_file_name_convert

Specify this clause only if the contents of the XML file do not accurately describe the locations of the source files. If the files that must be used to plug in the source database are no longer in the location specified in the XML file, then use this clause to map the specified file names to the actual file names.

- For *filename_pattern*, specify the string for the location of the files as specified in the XML file.
- For *replacement_filename_pattern*, specify the string for the actual location that contains the files that must be used to create the PDB.

Oracle Database will replace *filename_pattern* with *replacement_filename_pattern* when searching for the source database files.

File name patterns cannot match files or directories managed by Oracle Managed Files.

If the files that must be used to create the PDB exist in the location specified in the XML file, you can either omit this clause or specify SOURCE_FILE_NAME_CONVERT=NONE.

source_file_directory

Specify this clause only if the contents of the XML file do not accurately describe the locations of the source files *and* the source files are all present in a single directory. This clause is

convenient when you have a large number of data files and specifying a replacement file name pattern for each file using the *source_file_name_convert* clause is not feasible.

- For *directory_path_name*, specify the absolute path of the directory that contains the source files. The directory is scanned to find the appropriate files based on the unplugged PDB's XML file.

You can specify this clause for configurations that use Oracle Managed Files and for configurations that do not use Oracle Managed Files.

If the files that must be used to create the PDB exist in the location specified in the XML file, you can either omit this clause or specify `SOURCE_FILE_DIRECTORY=NONE`.

COPY

Specify `COPY` if you want the files listed in the XML file to be copied to the new location and used for the new PDB. This is the default. You can use the optional *file_name_convert* clause to use pattern replacement in the new file names. Refer to *file_name_convert* for the full semantics of this clause.

MOVE

Specify `MOVE` if you want the files listed in the XML file to be moved, rather than copied, to the new location and used for the new PDB. You can use the optional *file_name_convert* clause to use pattern replacement in the new file names. Refer to *file_name_convert* for the full semantics of this clause.

If the storage locations are different mounts, or if the storage locations do not support move at the OS or storage level, then the `MOVE` clause first copies the files then deletes the originals.

NOCOPY

Specify `NOCOPY` if you want the files for the PDB to remain in their current locations. Use this clause if there is no need to copy or move the files required to plug in the PDB.

service_name_convert

Use this clause to determine how the database renames services for the new PDB. Refer to *service_name_convert*::= for the full semantics of this clause.

default_tablespace

Use this clause to specify a permanent default tablespace for the PDB. Oracle Database will assign the default tablespace to any non-`SYSTEM` user for whom a different permanent tablespace is not specified. The *tablespace* must already exist in the source database. Because the tablespace already exists, you cannot specify the `DATAFILE` clause or the *extent_management_clause* when creating a PDB with the *create_pdb_from_xml* clause.

pdb_storage_clause

Use this clause to specify storage limits for the new PDB. Refer to *pdb_storage_clause* for the full semantics of this clause.

path_prefix_clause

Use this clause to ensure that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. Refer to *path_prefix_clause* for the full semantics of this clause.

tempfile_reuse_clause

Specify `TEMPFILE REUSE` to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. Refer to *tempfile_reuse_clause* for the full semantics of this clause.

HOST and PORT

These clauses are useful only if you are creating a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB. Refer to HOST and PORT for the full semantics of these clauses.

create_pdb_from_mirror_copy

Specify this clause to create a pluggable database *new_pdb_name* using the prepared files of the mirror copy *mirror_name*. The new PDB will be split from the source database using the prepared files created by the *prepare_clause*.

- You must execute this clause from the root container.
- The meaning of the other optional parameters remains unchanged by this clause.
- You can only split one database from a prepared mirror copy. If you want to create additional splits, you must prepare a new mirror copy.
- You can specify the database link name after you have specifed the mirror copy name in the *prepare_clause* of the `ALTER PLUGGABLE DATABASE` statement. In addition, the current CDB name should match the target CDB name specified in the *prepare_clause*. You must be a valid user in the CDB being referenced by the database link with the system privileges `CREATE SESSION` and `CREATE PLUGGABLE DATABASE`.
- If the database link name is omitted, then the base PDB name is looked up in the current CDB.

using_snapshot_clause

Specify this clause to create a PDB using an existing PDB snapshot that can be identified by its name, SCN, or timestamp.

If you create a PDB specifying `SNAPSHOT COPY`, then the new PDB will depend on the existence of the PDB snapshot. This will affect your ability to drop or purge the PDB.

container_map_clause

Specify this clause in CDB Root, Application Root or both to dynamically update changes as they happen to the new PDB.

You must note the following points with container maps:

- The `container_map_clause` is optional.
- The `add_partition_clause` will add a new partition to the container map defined in the Root (CDB Root and/or Application Root) of the new PDB.
- The `split_partition_clause` will split an existing partition of the container map defined in the Root (CDB Root and/or Application Root) of the new PDB.
- In the absence of `add_partition_clause` and `split_partition_clause`, container map defined in the Root of the new PDB is not updated.

- For PDB relocate, container map defined in the Root (CDB Root and/or Application Root) of the source PDB are automatically updated to reflect the “drop” of the source PDB.
- Dynamic maintenance of container map defined using hash partitioning is not supported

Add a New Partition to a Range-Partitioned Container Map: Example

```
CREATE PLUGGABLE DATABASE cdb1_pdb3
  ADMIN USER IDENTIFIED BY manager
  FILE_NAME_CONVERT=('cdb1_pdb0, cdb1_pdb3')
  CONTAINER_MAP UPDATE (ADD PARTITION cdb1_pdb3 VALUES LESS THAN (100));
  ALTER PLUGGABLE DATABASE cdb1_pdb3 OPEN
```

Split an Existing Partition of a Range-Partitioned Container Map to Create a New Partition: Example

```
CREATE PLUGGABLE DATABASE cdb1_pdb4
  ADMIN USER IDENTIFIED BY manager
  FILE_NAME_CONVERT=('cdb1_pdb0, cdb1_pdb4')
  CONTAINER_MAP UPDATE (SPLIT PARTITION cdb1_pdb3
                          AT (50)
                          INTO
                          (PARTITION cdb1_pdb3, PARTITION cdb1_pdb3)
  ALTER PLUGGABLE DATABASE cdb1_pdb4 OPEN
```

Verify Updated in Range-Partitioned Container Map : Example

```
SELECT partition_name, high_value
  FROM dba_tab_partitions
  WHERE table_name='MAP' AND table_owner='SYS'
```

pdb_snapshot_clause

Specify this clause if you want to be able to create PDB snapshots.

- `NONE` is the default. It means that no snapshots of the PDB can be created.
- `MANUAL` means that the PDB snapshot can *only* be created manually.
- If snapshot interval is specified, PDB snapshots will be created automatically at specified interval. In addition, a user will also be able to create PDB snapshots manually
- If expressed in minutes, `snapshot_interval` must be less than 3000.
- If expressed in hours, `snapshot_interval` must be less than 2000.

create_pdb_decrypt_from_xml

You must have the `SYSKM` privilege to execute this command.

For PDBs in **united** mode, the following restrictions apply:

- You must specify the clause if you are using a TDE protected database. Otherwise it is optional.
- You need not specify the clause for an isolated PDB.
- The wallet must be open in `ROOT`.
- The wallet file is copied in all cases: `NOCOPY`, `COPY`, and `MOVE`.

Plugging a PDB from an XML Metadata File: Example

```
CREATE PLUGGABLE DATABASE CDB1_PDB2 USING '/tmp/cdb1_pdb2.xml' NOCOPY
KEYSTORE IDENTIFIED BY keystore_password DECRYPT USING transport_secret
```

Plugging a PDB from an Archive File: Example

```
CREATE PLUGGABLE DATABASE CDB1_PDB1_1_C USING '/tmp/cdb1_pdb3.pdb' DECRYPT USING
transport_secret
```

For PDBs in **isolated** mode, you need not specify `DECRYPT USING transport_secret`. This is not required because the wallet file is copied during the creation of an unplugged PDB from an XML file. if you are creating a PDB from an archive file with the `.pdb` extension, the wallet file of the PDB is available in the zipped archive.

If the `ewallet.p12` file already exists at the destination, a backup is automatically initiated. The backup file has the following format: `ewallet_PLGDB_2017090517455564.p12`.

Examples

Creating a PDB by Using the Seed: Example

The following statement creates a PDB `salespdb` by using the seed in the CDB as a template. The administrative user `salesadm` is created and granted the `dba` role. The default tablespace assigned to any non-`SYSTEM` users for whom no permanent tablespace is assigned is `sales`. File names for the new PDB will be constructed by replacing `/disk1/oracle/dbs/pdbseed/` in the file names in the seed with `/disk1/oracle/dbs/salespdb/`. All tablespaces that belong to `sales` must not exceed 2G. The location of all directory object paths associated with `salespdb` are restricted to the directory `/disk1/oracle/dbs/salespdb/`.

```
CREATE PLUGGABLE DATABASE salespdb
  ADMIN USER salesadm IDENTIFIED BY password
  ROLES = (dba)
  DEFAULT TABLESPACE sales
    DATAFILE '/disk1/oracle/dbs/salespdb/sales01.dbf' SIZE 250M AUTOEXTEND ON
  FILE_NAME_CONVERT = ('/disk1/oracle/dbs/pdbseed/',
                       '/disk1/oracle/dbs/salespdb/')
  STORAGE (MAXSIZE 2G)
  PATH_PREFIX = '/disk1/oracle/dbs/salespdb/';
```

Cloning a PDB From an Existing PDB: Example

The following statement creates a PDB `newpdb` by cloning PDB `salespdb`. PDBs `newpdb` and `salespdb` are in the same CDB. Because no storage limits are explicitly specified, there is no limit on the amount of storage for `newpdb`. The files are copied from `/disk1/oracle/dbs/salespdb/` to `/disk1/oracle/dbs/newpdb/`. The location of all directory object paths associated with `newpdb` are restricted to the directory `/disk1/oracle/dbs/newpdb/`.

```
CREATE PLUGGABLE DATABASE newpdb FROM salespdb
  FILE_NAME_CONVERT = ('/disk1/oracle/dbs/salespdb/', '/disk1/oracle/dbs/newpdb/')
  PATH_PREFIX = '/disk1/oracle/dbs/newpdb';
```

Plugging a PDB into a CDB: Example

The following statement plugs the PDB `salespdb`, which was previously unplugged, into the CDB. The details about the metadata describing `salespdb` are stored in the XML file `/disk1/usr/salespdb.xml`. The XML file does not accurately describe the current locations of the files. Therefore, the `SOURCE_FILE_NAME_CONVERT` clause is used to indicate that the files are in `/disk2/oracle/dbs/salespdb/`, not `/disk1/oracle/dbs/salespdb/`. The `NOCOPY` clause indicates that the files are already in the correct location. All tablespaces that belong to `sales` must not exceed 2G. A file with the same name as the temp file specified in the XML file exists in the target location. Therefore, the `TEMPFILE REUSE` clause is required.

```
CREATE PLUGGABLE DATABASE salespdb
  USING '/disk1/usr/salespdb.xml'
```

```
  SOURCE_FILE_NAME_CONVERT =
    ('/disk1/oracle/dbs/salespdb/', '/disk2/oracle/dbs/salespdb/')
  NOCOPY
  STORAGE (MAXSIZE 2G)
  TEMPFILE REUSE;
```

CREATE PMEM FILESTORE

Purpose

You can create a persistent memory file store with this statement.

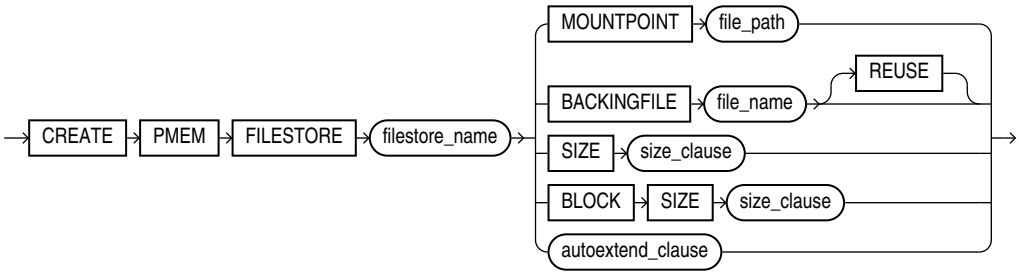
Prerequistes

You must have `SYSDBA` privileges to execute `CREATE PMEM FILESTORE` .

You must execute this statement from `CDB$ROOT`.

Syntax

***create_pmem_filestore*::=**



Semantics

MOUNTPOINT

`file_path` contains the final directory name and must match the PMEM file store name. If there is no match, the statement will fail.

You must start database instance with at least `NOMOUNT` mode.

It is recommeded to use a `spfile` for the database `init.ora` file.

When you use a `spfile` , the `CREATE PMEM FILESTORE` command automatically writes the necessary `init.ora` parameters into the `spfile` to remember the configuration. If you do not use a `spfile` , you must explicitly add the required parameters to `init.ora` so that the next database instance startup will automatically mount the PMEM file store.

Example

```
CREATE PMEM FILESTORE cloud_db_1 MOUNTPOINT '/corp/db/cloud_db_1'
    BACKINGFILE '/var/pmem/foo_1.' SIZE 2T BLOCKSIZE 8K
    AUTOEXTEND ON NEXT 10G MAXSIZE 3T
```

CREATE PROCEDURE

Purpose

Procedures are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `CREATE PROCEDURE` statement to create a standalone stored procedure or a call specification.

A **procedure** is a group of PL/SQL statements that you can call by name. A **call specification** (sometimes called call spec) declares a Java method, a JavaScript method, or a third-generation language (3GL) routine so that it can be called from SQL and PL/SQL. The call spec tells Oracle Database which Java method, JavaScript function, or third-generation language (3GL) routine to invoke when a call is made. It also tells the database what type conversions to make for the arguments and return value.

Stored procedures offer advantages in the areas of development, integrity, security, performance, and memory allocation.

See Also:

- *JavaScript Developer's Guide*
- CREATE MLE MODULE
- CREATE MLE ENV
- *Oracle Database Development Guide* for more information on stored procedures, including how to call stored procedures and for information about registering external procedures.
- CREATE FUNCTION for information specific to functions, which are similar to procedures in many ways.
- CREATE PACKAGE for information on creating packages. The `CREATE PROCEDURE` statement creates a procedure as a standalone schema object. You can also create a procedure as part of a package.
- ALTER PROCEDURE and DROP PROCEDURE for information on modifying and dropping a standalone procedure.
- CREATE LIBRARY for more information about shared libraries.

Prerequisites

To create or replace a procedure in your own schema, you must have the `CREATE PROCEDURE` system privilege. To create or replace a procedure in another user's schema, you must have the `CREATE ANY PROCEDURE` system privilege.

To invoke a call spec, you may need additional privileges, for example, the `EXECUTE` object privilege on the C library for a C call spec.

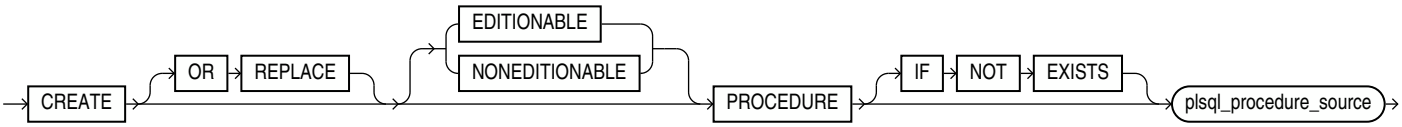
To embed a `CREATE PROCEDURE` statement inside an Oracle precompiler program, you must terminate the statement with the keyword `END-EXEC` followed by the embedded SQL statement terminator for the specific language.

> **See Also:**
>
> *Oracle Database PL/SQL Language Reference* or *Oracle Database Java Developer's Guide* for more information

Syntax

Procedures are defined using PL/SQL. Alternatively they can refer to non-PL/SQL code such as Java, JavaScript, C, and others by means of call specifications. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

***create_procedure*::=**



(*plsql_procedure_source*: See *Oracle Database PL/SQL Language Reference*.)

Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the procedure if it already exists. Use this clause to change the definition of an existing procedure without dropping, re-creating, and regranting object privileges previously granted on it. If you redefine a procedure, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined procedure can still access the procedure without being regranted the privileges.

If any function-based indexes depend on the procedure, then Oracle Database marks the indexes `DISABLED`.

> **See Also:**
>
> ALTER PROCEDURE for information on recompiling procedures

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the procedure does not exist, a new procedure is created at the end of the statement.
- If the procedure exists, this is the procedure you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

[EDITIONABLE | NONEDITIONABLE]

Use these clauses to specify whether the procedure is an editioned or noneditioned object if editioning is enabled for the schema object type `PROCEDURE` in *`schema`*. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

plsql_procedure_source

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the *`plsql_procedure_source`*.

CREATE PROFILE

> **Note:**
>
> Oracle recommends that you use the Database Resource Manager rather than this SQL statement to establish resource limits. The Database Resource Manager offers a more flexible means of managing and tracking resource use. For more information on the Database Resource Manager, refer to *Oracle Database Administrator's Guide.*

Purpose

Use the `CREATE PROFILE` statement to create a **profile**, which is a set of limits on database resources. If you assign the profile to a user, then that user cannot exceed these limits.

To specify resource limits for a user, you must:

- Enable resource limits dynamically with the `ALTER SYSTEM` statement or with the initialization parameter `RESOURCE_LIMIT`. This parameter does not apply to password resources. Password resources are always enabled.
- Create a profile that defines the limits using the `CREATE PROFILE` statement
- Assign the profile to the user using the `CREATE USER` or `ALTER USER` statement

In a multitenant environment, different profiles can be assigned to a common user in the root and in a PDB. When the common user logs in to the PDB, a profile whose setting applies to the session depends on whether the settings are password-related or resource-related.

- Password-related profile settings are fetched from the profile that is assigned to the common user in the root. For example, suppose you assign a common profile `c##prof` (in which `FAILED_LOGIN_ATTEMPTS` is set to 1) to common user `c##admin` in the root. In a PDB that user is assigned a local profile`local_prof` (in which `FAILED_LOGIN_ATTEMPTS` is set to 6.) Common user `c##admin` is allowed only one failed login attempt when he or she tries to log in to the PDB where `loc_prof` is assigned to him.
- Resource-related profile settings specified in the profile assigned to a user in a PDB get used without consulting resource-related settings in a profile assigned to the common user

in the root. For example, if the profile `local_prof` that is assigned to user `c##admin` in a PDB has `SESSIONS_PER_USER` set to 2, then `c##admin` is only allowed only 2 concurrent sessions when he or she logs in to the PDB `loc_prof` is assigned to him, regardless of value of this setting in a profile assigned to him in the root.

> **See Also:**
>
> *Oracle Database Security Guide* for a detailed description and explanation of how to use password management and protection

Prerequisites

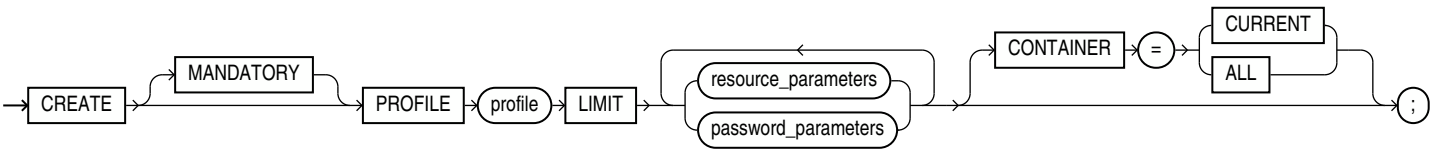
To create a profile, you must have the `CREATE PROFILE` system privilege.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

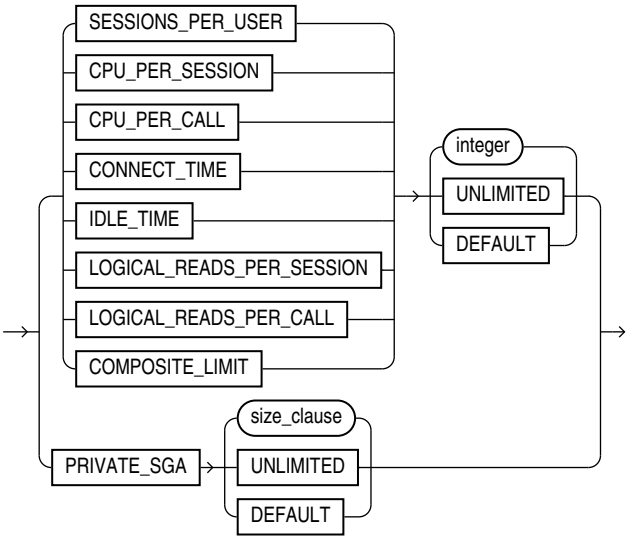
> **See Also:**
>
> - ALTER SYSTEM for information on enabling resource limits dynamically
> - *Oracle Database Reference* for information on the `RESOURCE_LIMIT` parameter
> - CREATE USER and ALTER USER for information on profiles

Syntax

***create_profile*::=**

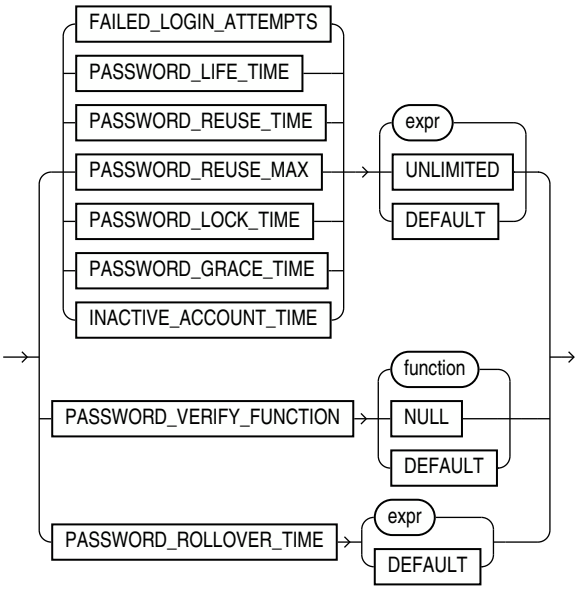


***resource_parameters*::=**



(*size_clause*::=

***password_parameters*::=**



Semantics

profile

Specify the name of the profile to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ". Use profiles to limit the database resources available to a user for a single call or a single session.

In a non-CDB, a profile name cannot begin with `C##` or `c##`.

> **Note:**
>
> A multitenant container database is the only supported architecture in Oracle Database 21c and later releases. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

In a CDB, the requirements for a profile name are as follows:

- The name of a **common profile** must begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, the prefix is `C##`.
- The name of a **local profile** must not begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. Regardless of the value of `COMMON_USER_PREFIX`, the name of a local profile can never begin with `C##` or `c##`.

> **Note:**
>
> If the value of `COMMON_USER_PREFIX` is an empty string, then there are no requirements for common or local profile names with one exception: the name of a local profile can never begin with `C##` or `c##`. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common profiles when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

Oracle Database enforces resource limits in the following ways:

- If a user exceeds the `CONNECT_TIME` or `IDLE_TIME` session resource limit, then the database rolls back the current transaction and ends the session. When the user process next issues a call, the database returns an error.
- If a user attempts to perform an operation that exceeds the limit for other session resources, then the database aborts the operation, rolls back the current statement, and immediately returns an error. The user can then commit or roll back the current transaction, and must then end the session.
- If a user attempts to perform an operation that exceeds the limit for a single call, then the database aborts the operation, rolls back the current statement, and returns an error, leaving the current transaction intact.

MANDATORY

Specify the keyword `MANDATORY` to create a generic mandatory profile in `CDB$ROOT`. You can use the mandatory profile to enforce password complexity requirements for database user accounts across the entire CDB or individual PDBs using the profile parameter *`password_verify_function`*.

The mandatory profile adds the password complexity requirement in addition to existing profile limits for common and local users. A PDB administrator cannot remove the password complexity requirement and allow users to set insecure shorter passwords, because mandatory profiles, just like common profiles, can only be altered in `CDB$ROOT` .

You can only use *password_verify_function* and *password_grace_time* profile parameters to define the limits for the mandatory profile.

Use the profile parameter *password_grace_time* to specify a grace period for user accounts in violation of mandatory password complexity requirements and whose passwords have to be changed.

The default value for *password_verify_function* is null. The default value for *password_grace_time* is 0.

User accounts imported using Oracle Data Pump are checked for password compliance against the mandatory profile and forced to change their passwords. If the password is not changed within the grace period, further connections are rejected. On import, the password is not checked for compliance against the mandatory profile because the password is hashed and cannot be decrypted. So the password is marked to expire after a configurable period set in the parameter PASSWORD_GRACE_TIME of the mandatory profile. Once the password expires, the new password is checked for compliance against the mandatory profile. Note that, post import, the mandatory password verification check can be performed ONLY when the user logs into the database. If the user does not login, the verification does not happen. In this case there is no way for the system to know that the password complies with mandatory profile's password complexity checks and MANDATORY_PROFILE_VIOLATION will continue to show up as NO for such users.

User-Created Password Complexity Function: Example

The example creates a password complexity function *my_mandatory_function* as the argument to PASSWORD_VERIFY_FUNCTION.

```
SQL> create or replace function my_mandatory_verify_function
 ( username     varchar2,
   password     varchar2,
   old_password varchar2)
 return boolean IS
begin
   -- mandatory verify function will always be evaluated regardless of the
   -- password verify function that is associated to a particular profile/user
   -- requires the minimum password length to be 8 characters
   if not ora_complexity_check(password, chars => 8) then
      return(false);
   end if;
   return(true);
end;
/
  2    3    4    5    6    7    8    9   10   11   12   13   14   15   16   17   18
Function created.
```

Create a Mandatory Profile: Example

The example creates mandatory profile c##cdb_profile. LIMIT restricts the profile to use the only profile parameter allowed, the PASSWORD_VERIFY_FUNCTION. The PASSWORD_VERIFY_FUNCTION specifies the user-created password complexity function my_mandatory_function.

```
CREATE MANDATORY PROFILE c##cdb_profile LIMIT PASSWORD_VERIFY_FUNCTION
my_mandatory_function
     CONTAINER = ALL ;
```

If you want to apply the mandatory user profile for all PDBs in the CDB, then you must do so in the CDB root using the ALTER SYSTEM statement.

Apply the Mandatory Profile to the Entire CDB: Example

You must be in `CDB$ROOT` to execute this statement.

```
ALTER SYSTEM SET MANDATORY_USER_PROFILE=c##cdb_profile;
```

If you want to apply the mandatory user profile for individual PDBs, then you must configure the `MANDATORY_USER_PROFILE` parameter in the `init.ora` file that is associated with the PDB.

Apply the Mandatory Profile to an Individual PDB: Example

Open the `init.ora` file associated with the PDB and set the `MANDATORY_USER_PROFILE`.

```
MANDATORY_USER_PROFILE=c##cdb_profile;
```

You can use `SHOW PARAMETER` to find the current `MANDATORY_USER_PROFILE` setting.

The mandatory profile that you set in `init.ora` takes precedence over the mandatory profile that you set with the `ALTER SYSTEM` statement in the CDB root.

Restrictions

- Only common users who have been commonly granted the `ALTER PROFILE` system privilege can alter or drop the mandatory profile, and only from the CDB root.
- Only a common user who has been commonly granted the `ALTER SYSTEM` privilege or has the `SYSDBA` administrative privilege can modify the `MANDTORY_USER_PROFILE` in the `init.ora` file.

Note:

- You can use fractions of days for all parameters that limit time, with days as units. For example, 1 hour is 1/24 and 1 minute is 1/1440.
- You can specify resource limits for users regardless of whether the resource limits are enabled. However, Oracle Database does not enforce the limits until you enable them.

See Also:

- Managing Security for Database Users
- "Creating a Profile: Example"

UNLIMITED

When specified with a resource parameter, `UNLIMITED` indicates that a user assigned this profile can use an unlimited amount of this resource. When specified with a password parameter, `UNLIMITED` indicates that no limit has been set for the parameter.

DEFAULT

Specify `DEFAULT` if you want to omit a limit for this resource in this profile. A user assigned this profile is subject to the limit for this resource specified in the `DEFAULT` profile. The `DEFAULT`

profile initially defines unlimited resources. You can change those limits with the `ALTER PROFILE` statement.

Any user who is not explicitly assigned a profile is subject to the limits defined in the `DEFAULT` profile. Also, if the profile that is explicitly assigned to a user omits limits for some resources or specifies `DEFAULT` for some limits, then the user is subject to the limits on those resources defined by the `DEFAULT` profile.

resource_parameters

SESSIONS_PER_USER

Specify the number of concurrent sessions to which you want to limit the user.

CPU_PER_SESSION

Specify the CPU time limit for a session, expressed in hundredth of seconds.

CPU_PER_CALL

Specify the CPU time limit for a call (a parse, execute, or fetch), expressed in hundredths of seconds.

CONNECT_TIME

Specify the total elapsed time limit for a session, expressed in minutes.

IDLE_TIME

Specify the permitted periods of continuous inactive time during a session, expressed in minutes. Long-running queries and other operations are not subject to this limit.

When you set an idle timeout of X minutes, note that the session will take X minutes, plus a couple of additional minutes to be terminated.

On the client application side, the error message shows up the next time, when the idle client attempts to issue a new command.

LOGICAL_READS_PER_SESSION

Specify the permitted number of data blocks read in a session, including blocks read from memory and disk.

LOGICAL_READS_PER_CALL

Specify the permitted number of data blocks read for a call to process a SQL statement (a parse, execute, or fetch).

PRIVATE_SGA

Specify the amount of private space a session can allocate in the shared pool of the system global area (SGA). Refer to *size_clause* for information on that clause.

> **Note:**
>
> This limit applies only if you are using shared server architecture. The private space for a session in the SGA includes private SQL and PL/SQL areas, but not shared SQL and PL/SQL areas.

COMPOSITE_LIMIT

Specify the total resource cost for a session, expressed in **service units**. Oracle Database calculates the total service units as a weighted sum of `CPU_PER_SESSION`, `CONNECT_TIME`, `LOGICAL_READS_PER_SESSION`, and `PRIVATE_SGA`.

> **See Also:**
>
> - ALTER RESOURCE COST for information on how to specify the weight for each session resource
> - "Setting Profile Resource Limits: Example"

password_parameters

Use the following clauses to set password parameters. Parameters that set lengths of time—that is, all the password parameters except `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_REUSE_MAX`—are interpreted in number of days. For testing purposes you can specify minutes (*n*/1440) or even seconds (*n*/86400) for these parameters. You can also use a decimal value for this purpose (for example .0833 for approximately one hour). The minimum value is 1 second. The maximum value is 24855 days. For `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_REUSE_MAX`, you must specify an integer.

FAILED_LOGIN_ATTEMPTS

Specify the number of consecutive failed attempts to log in to the user account before the account is locked. If you omit this clause, then the default is 10 times.

PASSWORD_LIFE_TIME

Specify the number of days the same password can be used for authentication. If you also set a value for `PASSWORD_GRACE_TIME`, then the password expires if it is not changed within the grace period, and further connections are rejected. If you omit this clause, then the default is 180 days.

> **See Also:**
>
> *Oracle Database Security Guide* for information on setting `PASSWORD_LIFE_TIME` to a low value

PASSWORD_REUSE_TIME and PASSWORD_REUSE_MAX

These two parameters must be set in conjunction with each other. `PASSWORD_REUSE_TIME` specifies the number of days which need to pass before a user having this profile can reuse one of their earlier passwords. `PASSWORD_REUSE_MAX` specifies the number of password changes required before the current password can be reused. For these parameters to have any effect, you must specify a value for both of them.

- If you specify a value for both of these parameters, then the user cannot reuse a password until the password has been changed the number of times specified for `PASSWORD_REUSE_MAX` during the number of days specified for `PASSWORD_REUSE_TIME`.

  For example, if you specify `PASSWORD_REUSE_TIME` to 30 and `PASSWORD_REUSE_MAX` to 10, then the user can reuse the password after 30 days if the password has already been changed 10 times.

- If you specify a value for either of these parameters and specify UNLIMITED for the other, then the user can never reuse a password.
- If you specify DEFAULT for either parameter, then Oracle Database uses the value defined in the DEFAULT profile. By default, the PASSWORD_REUSE_TIME and PASSWORD_REUSE_MAX parameters are set to UNLIMITED in the DEFAULT profile. If you have not changed the default setting of UNLIMITED in the DEFAULT profile, then the database treats the value for that parameter as UNLIMITED.
- If you set both of these parameters to UNLIMITED, then the database ignores both of them. This is the default if you omit both parameters.

PASSWORD_LOCK_TIME

Specify the number of days an account will be locked after the specified number of consecutive failed login attempts. If you omit this clause, then the default is 1 day.

PASSWORD_GRACE_TIME

Specify the number of days after the grace period begins during which a warning is issued and login is allowed. If you omit this clause, then the default is 7 days.

INACTIVE_ACCOUNT_TIME

Specify the permitted number of consecutive days of no logins to the user account, after which the account will be locked. The minimum value is 15 days. The maximum value is 24855. If you omit this clause, then the default is UNLIMITED.

PASSWORD_VERIFY_FUNCTION

You can pass a PL/SQL password complexity verification script as an argument to CREATE PROFILE by specifying PASSWORD_VERIFY_FUNCTION. Oracle Database provides a default script, but you can write your own function or use third-party software instead.

- For *function*, specify the name of the password complexity verification function. The function must exist in the SYS schema, and you must have EXECUTE privilege on the function.
- Specify NULL to indicate that no password verification is performed.

If you specify *expr* for any of the password parameters, then the expression can be of any form except scalar subquery expression.

Restriction on Password Parameters

When you assign a profile to an external user or a global user, the password parameters do not take effect for that user.

> **See Also:**
>
> "Setting Profile Password Limits: Example"

PASSWORD_ROLLOVER_TIME

You must configure a non-zero limit for the PASSWORD_ROLLOVER_TIME user profile parameter in order to enable the gradual database password rollover. You can configure this parameter using CREATE PROFILE or ALTER PROFILE.

Use *expr* to specify a value for PASSWORD_ROLLOVER_TIME in days. You must specify hours as a fraction of one day. For example, if you want to set the limit to four hours, *expr* would be 4/24 .

The granularity of the PASSWORD_ROLLOVER_TIME limit value is one second. For example, you can have a limit of one hour plus three minutes and five seconds by providing an *expr* like this: (1/24) + (3/1440) + (5/86400)) .

The default setting for PASSWORD_ROLLOVER_TIME is 0, which means that gradual password rollover is disabled.

Example

The example sets the gradual password rollover time period to 1 day:

```
CREATE PROFILE usr_prof LIMIT PASSWORD_ROLLOVER_TIME 1
```

Limits on PASSWORD_ROLLOVER_TIME:

- Specify a value of 0 for PASSWORD_ROLLOVER_TIME if you want to disable the password rollover period.
- Specify a positive value for PASSWORD_ROLLOVER_TIME to enable the password rollover feature for all users who are members of the profile.
- The minimum value you can specify for PASSWORD_ROLLOVER_TIME is one hour. You do this by entering 1/24. If you want to set the password rollover time to six hours, you enter 6/24 as the value for PASSWORD_ROLLOVER_TIME .
- The value for PASSWORD_ROLLOVER_TIME cannot exceed either 60 days, or the current value of the PASSWORD_GRACE_TIME limit of the profile, or the current value of the PASSWORD_LIFE_TIME limit of the profile; whichever is lowest.

To find user accounts that are currently in the password rollover period, query the ACCOUNT_STATUS column of the DBA_USERS data dictionary view. The status will be IN ROLLOVER.

The password rollover period begins the moment the user changes their password.

> **See Also:**
>
> Configuring Authentication

CONTAINER Clause

The CONTAINER clause applies when you are connected to a CDB. However, it is not necessary to specify the CONTAINER clause because its default values are the only allowed values.

- To create a common profile, you must be connected to the root. You can optionally specify CONTAINER = ALL, which is the default when you are connected to the root.
- To create a local profile, you must be connected to a PDB. You can optionally specify CONTAINER = CURRENT, which is the default when you are connected to a PDB.

Examples

Creating a Profile: Example

The following statement creates the profile new_profile:

```
CREATE PROFILE new_profile
  LIMIT PASSWORD_REUSE_MAX 10
        PASSWORD_REUSE_TIME 30;
```

Setting Profile Resource Limits: Example

The following statement creates the profile `app_user`:

```
CREATE PROFILE app_user LIMIT
   SESSIONS_PER_USER          UNLIMITED
   CPU_PER_SESSION            UNLIMITED
   CPU_PER_CALL               3000
   CONNECT_TIME               45
   LOGICAL_READS_PER_SESSION  DEFAULT
   LOGICAL_READS_PER_CALL     1000
   PRIVATE_SGA                15K
   COMPOSITE_LIMIT            5000000;
```

If you assign the `app_user` profile to a user, then the user is subject to the following limits in subsequent sessions:

- The user can have any number of concurrent sessions.
- In a single session, the user can consume an unlimited amount of CPU time.
- A single call made by the user cannot consume more than 30 seconds of CPU time.
- A single session cannot last for more than 45 minutes.
- In a single session, the number of data blocks read from memory and disk is subject to the limit specified in the `DEFAULT` profile.
- A single call made by the user cannot read more than 1000 data blocks from memory and disk.
- A single session cannot allocate more than 15 kilobytes of memory in the SGA.
- In a single session, the total resource cost cannot exceed 5 million service units. The formula for calculating the total resource cost is specified by the `ALTER RESOURCE COST` statement.
- Since the `app_user` profile omits a limit for `IDLE_TIME` and for password limits, the user is subject to the limits on these resources specified in the `DEFAULT` profile.

Setting Profile Password Limits: Example

The following statement creates the `app_user2` profile with password limits values set:

```
CREATE PROFILE app_user2 LIMIT
   FAILED_LOGIN_ATTEMPTS 5
   PASSWORD_LIFE_TIME 60
   PASSWORD_REUSE_TIME 60
   PASSWORD_REUSE_MAX 5
   PASSWORD_VERIFY_FUNCTION ora12c_verify_function
   PASSWORD_LOCK_TIME 1/24
   PASSWORD_GRACE_TIME 10
   INACTIVE_ACCOUNT_TIME 30;
```

This example uses the default Oracle Database password verification function, `ora12c_verify_function`. Refer to *Oracle Database Security Guide* for information on using this verification function provided or designing your own verification function.

CREATE PROPERTY GRAPH

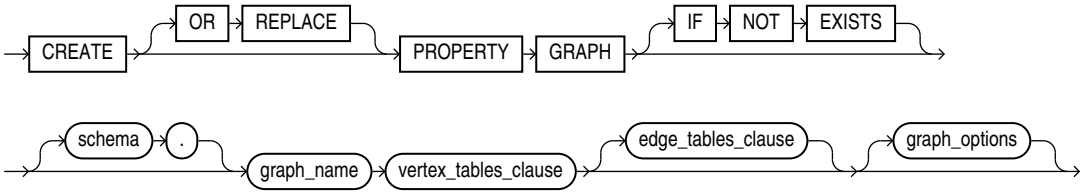
Purpose

Use `CREATE PROPERTY GRAPH` to create a property graph from existing schema objects. The schema object can be a table, an external table, a materialized view or a synonym of the table, external table, or materialized view.

Prerequistes

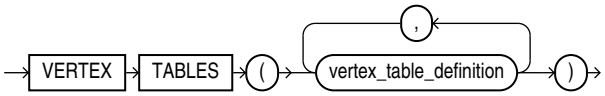
You need the `CREATE PROPERTY GRAPH` privilege to create a property graph in your own schema. To create a property graph in any schema except `SYS` and `AUDSYS`, you must have the `CREATE ANY PROPERTY GRAPH` privilege.

Syntax

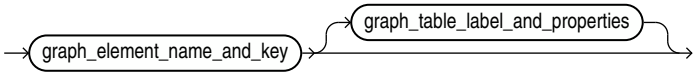


(edge_tables_clause::= , graph_options)

***vertex_tables_clause*::=**

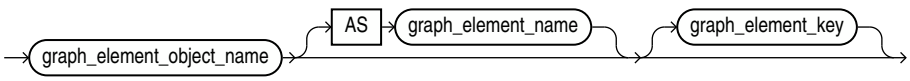


***vertex_table_definition*::=**

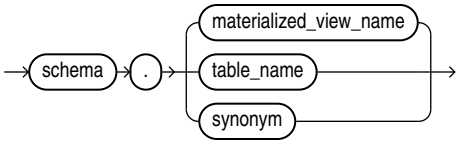


graph_table_level_and_properties

***graph_element_name_and_key*::=**

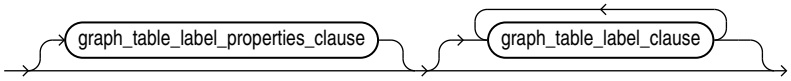


***graph_element_object_name*::=**

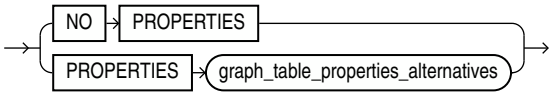


***graph_element_key*::=**

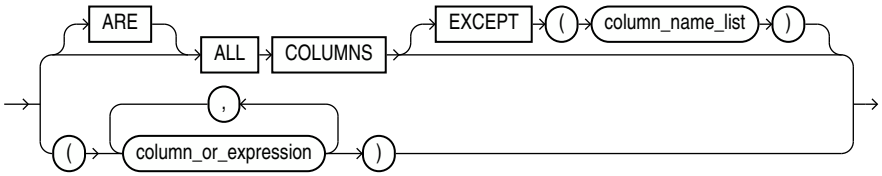
***graph_table_label_and_properties*::=**



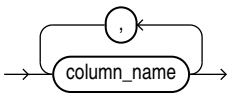
***graph_table_label_properties_clause*::=**



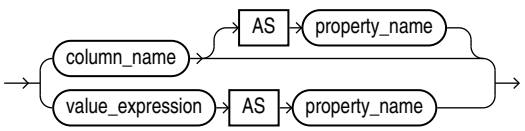
***graph_table_properties_alternatives*::=**



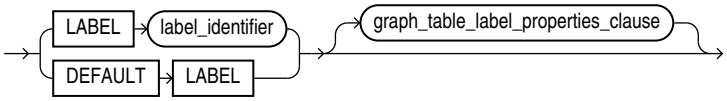
***column_name_list*::=**



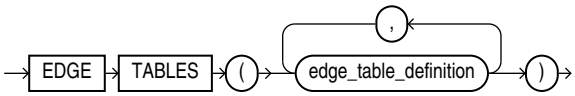
***column_or_expression*::=**



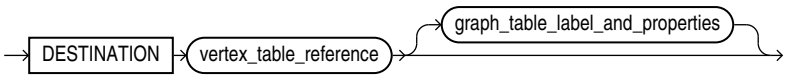
***graph_table_label_clause*::=**



***edge_tables_clause*::=**

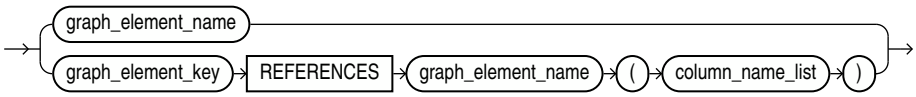


***edge_tables_definition*::=**

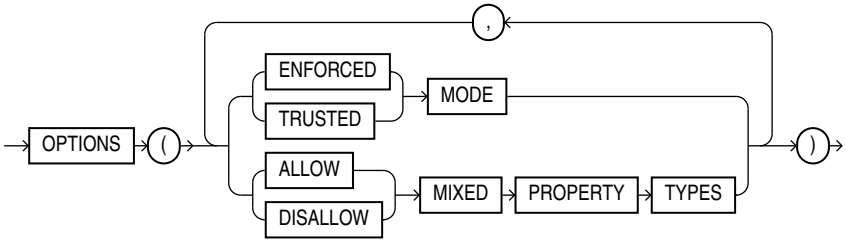


graph_table_level_and_properties

***vertex_table_reference*::=**



***graph_options*::=**



Semantics

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the property graph does not exist, a new property graph is created at the end of the statement.
- If the property graph exists, the existing property graph is what you have at the end of the statement. A new one is not created because the older one is detected.

Using `IF EXISTS` with `CREATE` results in the following error: Incorrect `IF NOT EXISTS` clause for `CREATE` statement .

You must create a property graph with the *`vertex_tables_clause`* .

Specify the schema to contain the property graph. If you omit schema, then Oracle Database creates the graph in your own schema.

The name of the property graph must not be used by any other object in the same schema, because property graphs share the name space used for tables and views. `ORA-00955` is raised in the case of name conflicts.

Specify `OR REPLACE` to re-create the property graph, if it already exists. You can use this clause to change the definition of an existing property graph without dropping, re-creating, and regranting object privileges previously granted on it.

If any materialized views are dependent on the property graph, then those materialized views will be marked `UNUSABLE` and will require a full refresh to restore them to a usable state. Invalid materialized views cannot be used by query rewrite and cannot be refreshed until they are recompiled.

vertex_tables_clause

The *`vertex_tables_clause`* lets you define one or more vertex tables for the property graph. A *`vertex_table_definition`* needs to specify the underlying object name. It can optionally specify more items (like labels and properties) as explained below.

You can define a property graph by specifying just the name of the underlying object used to define the graph element table. In this case a default label with the same name as the underlying table is created and all the columns are exposed as graph properties.

The object name can be the name of a table, an external table, a materialized view, or a synonym of a table or materialized view.

The object name can be qualified by specifying the schema it resides in. This means that you can use objects from other schemas to define a graph element table. If no option is specified, the name of the specified object is used as the name of the graph element table.

Example: Create a Property Graph with Vertex Table

In the following example, the vertex table name `my_table_1` is the name of underlying object `my_table_1`.

```
CREATE PROPERTY GRAPH “myGraph” VERTEX TABLES (my_table_1);
```

Example: Create a Property Graph with a Schema-Qualified Vertex Table

In the following example, the name `my_table_1` is qualified by the schema `other_schema` and the vertex table name is the name of underlying object `my_table_1`.

```
CREATE PROPERTY GRAPH “myGraph” VERTEX TABLES (other_schema.my_table_1);
```

graph_element_name_and_key

The *`graph-element-name-and-key`* clause lets you specify:

- The name of the schema object to be used for defining a graph element table. The name of the graph element table defaults to the *graph_element_object_name* without the schema qualification, if an AS clause is not used to provide an alternative name.
- One or more column names used to explicitly specify what columns of the underlying object are used to identify a row in that underlying object.

Graph element table names are defined in a name space specific to the property graph: they do not conflict with the names of schema objects, nor with the names of graph element tables defined in other property graphs. This implies also that an edge table cannot use the name of a vertex table. Graph element table names follow the same rules as other identifiers: they may be quoted to indicate case-sensitivity, and are limited by default to 128 characters. Any subsequent symbolic references to a graph element table in the DDL statement must use the graph element table name, not the name of its underlying object. In particular, you must use the graph element table name when you define the source and destination vertex table of an edge table.

graph_element_object_name identifies the table or the materialized view directly or indirectly using a synonym for the table or the materialized view.

You can omit the clause *graph-element-key* in the following cases:

- The clause *graph_element_object_name* identifies a base table with a single primary key constraint. The primary key constraint takes precedence over any unique key that might also be defined.
- The clause *graph_element_object_name* identifies a base table without primary keys and a single unique key constraint where all columns are not nullable.

You must specify *graph-element-key* when *object_name* identifies a materialized view.

Example

The example shows the ways *graph-element-key* is used. In vertex table VT3 it is used to specify a composite key made of multiple columns of the underlying table. Vertex table ALTVT2 is defined from the same underlying object used to define vertex table VT2, but a different column of that object (PK4) is specified as identifier for its vertices. It is assumed that vertex table VT1 has a primary key constraint or unique key with not null columns.

```
CREATE PROPERTY GRAPH "myGraph"
     VERTEX TABLES (
       VT1,
       VT2 KEY(PK2),
       VT3 KEY(PK31, PK32),
       VT2 AS ALTVT2 KEY(PK4)
     );
```

Note that a same underlying object VT2 can be used to define another graph element table using the same primary key used to define other graph element tables from VT2. So in the example above, specifying PK2 instead of PK4 for ALTVT2 is allowed.

When the *graph-element-key* clause is present, all the declared column names must match column names of the underlying object of the graph element table.

When the *graph-element-key* clause is omitted, the database will infer the columns from the constraints of the underlying object. If multiple primary or unique key constraints are defined for that object, inferring a key fails and an error is raised. Note that the primary constraint is only used to infer the key for the graph element table, no dependency to the constraint is created as a result of this inference. This means that the constraint may be dropped later without invalidating the graph or impact to its definition.

You can change this behavior and create a dependency to the constraint with the `ENFORCED MODE` option.

You can define multiple graph element tables from the same object. For example, a table may act as a different edge table in the same graph. You can also define a graph from tables from different schemas but with the same name. In both cases you must take care to avoid name collisions by specifying an alternative graph element table name with the optional `AS` clause.

Example: Create a Property Graph with the AS Clause

```
CREATE PROPERTY GRAPH "myGraph" VERTEX TABLES (my_table_1, other_schema.my_table_1 AS
my_table2);
```

Restrictions

Restrictions that apply on primary key constraints also apply on vertex and edge table keys:

- Columns of the following built-in data types can be used to define keys of vertex or edge tables: `VARCHAR2`, `NVARCHAR2`, `NUMBER`, `BINARY_FLOAT`, `BINARY_DOUBLE`, `CHAR`, `NCHAR`, `DATE`, `INTERVAL` (both `YEAR TO MONTH` and `DAY TO SECOND`), and `TIMESTAMP` (but not `TIMESTAMP WITH TIME ZONE`).
- A composite key cannot exceed 32 columns.

edge_tables_clause

Use *edge_tables_clause* to specify one or more *edge_table_definition* clauses. Each *edge_table_definition* clause specifies the underlying object used to define the edge table of the graph.

edge_table_definition

Use *edge_table_definition* to explicitly define the vertex table that acts as the source of the edge, and the vertex table that acts as the destination of the edge using the keywords `SOURCE` and `DESTINATION`.

vertex_table_reference

The source and destination of the edge specify a *vertex_table_reference*. The *vertex_table_reference* specifies three components:

- The graph element name of a vertex table, *graph_element_name*
- A list of columns of the edge table to be treated as foreign key *graph_element_key*.
- A list of columns of the referenced vertex table to be treated as referenced keys *column_name_list*

The *graph_element_name* of a *vertex_table_reference* clause must be defined by a preceding *vertex_tables_definition* clause. A vertex table name defined in the *vertex_tables_definition* may be used to define multiple edge table definitions, either as a source for the edge, a destination, or both.

Example

Given the following vertex tables defined as follows:

```
CREATE PROPERTY GRAPH "myGraph"
     VERTEX TABLES (
       VT1,
       VT2 KEY(PK2),
       VT3 KEY(PK31, PK32),
```

```
      VT2 AS ALTVT2 KEY(PK4)
    )
    EDGE TABLES (
      E1 SOURCE VT1
         DESTINATION VT2,
      E2 SOURCE      KEY(FK1) REFERENCES VT1 (PK1)
         DESTINATION KEY(FK2) REFERENCES VT2 (PK2),
      E3 SOURCE      KEY(FK1) REFERENCES VT1 (PK1)
         DESTINATION VT2,
      E4 SOURCE VT1
         DESTINATION KEY(FK5) REFERENCES VT2(RK5))
;
```

Both vertex-table-reference from edge table `E1` to, respectively, source table `VT1` and destination table `VT2` are declared implicitly. When using this syntax, the user relies on the database to infer source and destination keys from existing foreign-key constraints between `E1` and, respectively, `VT1` and `VT2`. In this case, there must be exactly only foreign-key constraints between `E1` and `VT1` (respectively, `VT2`).

If that is not the case an error is raised. Note that the foreign key constraint is only used to infer the foreign key relationships between an edge table and its source and destination vertex tables. No dependency to the foreign key constraint is created as a result of this inference. This means that the constraint may be dropped later without invalidating the graph or impact to its definition.

In contrast, both vertex-table-references from edge table `E2`, respectively, source vertex table `VT1` and destination vertex table `VT2` are declared explicitly. This syntax is mandatory when there are no or multiple foreign constraints defined between `E2` and its referenced vertex tables.

Implicit and explicit syntax can be mixed, as shown for edge table `E3` and `E4`, wherein the former uses an explicit syntax only of the source table, while the latter uses it only for the destination table.

Note that the *`column_name_list`* clause that specifies the columns of the underlyng object for the referenced vertex table to be treated as referenced key don't necessarily match the columns specified in the graph-element-key sub-clause of the vertex-definition clause that defined the referenced vertex table. This is illustrated with edge table E4 from the example above: the referenced key specified for `VT2` is `RK5`, whereas the key that was specified in the vertex table definition clause for `VT2` was `PK2`.

graph_table_label_and_properties

Use *`graph_table_label_and_properties`* to specify the labels and properties of a graph. Then you can formulate graph queries using the labels of a graph and the properties defined by these labels.

Graph Labels and Properties

You can associate graph element tables with labels that expose the columns of the underlying object as properties. A label has a name and declares a mapping of property names to columns of the underlying object for a given graph element table. Labels give you a way to refer to one or more graph element tables in a graph query using a same label name. Properties give you a way to refer to columns of one or more graph element tables using a same, possibly label qualified, property name.

You can associate one label to multiple graph element tables, provided that all the graph element tables that share this label declare the same property name. The columns or value expressions exposed by the same property name must have union compatible types.

A graph element table may be associated with multiple labels.

Graph element tables are always associated with at least one label. If none is defined explicitly, a label is assigned automatically with the same name as the graph element table.

Declaring labels and properties is optional. All the following ways to explicitly declare properties and labels are valid:

- Only properties using *graph_table_label_properties_clause*
- Only labels using *graph_table_label_clause*
- Both properties and labels using *graph_table_label_properties_clause*
- No properties or labels

graph_table_label_properties_clause

The properties are derived from columns or SQL value expressions of columns of the underlying object used to define the graph element table. By default, all visible columns are mapped to properties and the names of the properties default to the names of these columns. Pseudo-columns cannot be exposed as a property.

The *graph_table_label_properties_clause* provides the following options:

- `PROPERTIES [ ARE ] ALL COLUMNS`

  All visible columns of the graph element table are exposed as properties of the label with the same names as the column names. (This is the default when no properties are specified.) Note that all visible columns that are used as keys will also be exposed as properties.

- `PROPERTIES [ ARE ] ALL COLUMNS EXCEPT(`*column_name_list*`)`

  All visible columns are exposed as properties of the label except for the ones explicitly listed. This option is useful, if the number of columns not supposed to be exposed as properties is small compared to the number of columns exposed as properties.

- `PROPERTIES (`*column_name_list*`)`

  Only the columns explicitly listed become properties of the label with the same names as the column names. This option is useful, if the number of columns exposed as properties is small compared to the number of columns not supposed to be exposed as properties, or if the user wants to expose invisible columns. It is also useful when renaming some or all of the properties is necessary, as shown in the following:

- `PROPERTIES(`*column_name_list AS property_name* `)`

  Only the columns explicitly listed become properties of the label. If `AS` *property_name* is appended to the *column_name*, then the *property_name* is used as the property name, otherwise the property name defaults to the column name. A property name can only be defined once per label. The `AS` clause is useful to enable association of one label to multiple graph element tables.

- `PROPERTIES (`*value_expression AS property_name, ...*`)`

  It is possible to define a property as an expression over columns of the underlying object used to define a graph element table. The `AS` clause is mandatory in this case. A value expression can be a scalar expression, or a function expression, or expression list. It can contain only the following forms of expression:

  – Columns of the underlying object

  – Constants: strings or numbers

  - Deterministic functions — either SQL built-in functions or PL/SQL functions

    No other expression forms are valid (in particular, sub-query expressions and aggregate functions are invalid). The expression can only return a scalar data type. SQL operator used in the expression must be deterministic

- `NO PROPERTIES`

  The label does not expose any column of the underlying object associated with the graph element table.

Note that that for a given vertex or edge table, the properties exposed in the various labels applied to this vertex or edge table must have the same definition.

graph_table_properties_alternatives

You can control explicitly what columns are exposed as properties using the options of *`graph_table_properties_alternatives`* clause.

Note that for implicit clauses, for example `ALL COLUMNS`, the list of exposed columns is determined when the graph is created. If you add additional columns to a table after you create the graph, for example you add a virtual column, the graph will not reflect the virtual column.

Examples

The following example illustrates various uses of *`graph_table_label_and_properties`* for declaring labels associated to graph element tables (here only vertex tables) and their properties:

```
CREATE PROPERTY GRAPH "myGraph"
  VERTEX TABLES (
    HR.VT1,
    VT1  AS ALTVT1,
    VT2  LABEL "foo" ,
    VT3  NO PROPERTIES,
    VT4  PROPERTIES(C1),
    VT5  PROPERTIES(C1, C2 as P2),
    VT6  LABEL "bar" LABEL "weighted" NO PROPERTIES,
    VT7  LABEL "bar2" PROPERTIES ARE ALL COLUMNS EXCEPT (C3),
    VT8  LABEL "weighted" NO PROPERTIES DEFAULT LABEL,
    VT9  PROPERTIES(Cx + Cy * 0.15 AS PX, Cz AS PZ),
    VT10 PROPERTIES(JSON_VALUE(JCOL,
      '$.person.creditScore[0]' returning number) AS CREDITSCORE,
    VT11 PROPERTIES(XMLCAST(XMLQUERY('/purchaseOrder/poDate'
       PASSING XCOL RETURNING CONTENT) AS DATE) AS PURCHASEDATE
 );
```

The meaning of each vertex table definition of the example:

- Vertex table `VT1` defines (implicitly) a single label `VT1` that exposes all the visible columns of the underlying object `HR.VT1`. This is the default when no options to specify label or property are used.
- Vertex table `ALTVT1` defines (implicitly) a single label `ALTVT1` that exposes all the visible columns of the underlying object `VT1`. If object name `VT1` resolves to `HR.VT1`, both vertex tables `ALTVT1` and `VT1` exposes the same columns from the same underlying object `HR.VT1`
- Vertex table `VT2` defines a single label `foo` that exposes all the visible columns of the underlying object `VT2`.
- Vertex table `VT3` defines (implicitly) a single label `VT3` without any properties. No columns from the underlying object `VT3` are exposed.

- Vertex table VT4 defines (implicitly) a single label VT4 with a single property C1 that exposes the column C1 of the underlying object VT4.
- Vertex table VT5 defines (implicitly) a single label VT5 with a two properties C1 and P2, that exposes, respectively, column C1 and C2 of the underlying object VT5.
- Vertex table VT6 defines two labels, bar and weighted, such that label bar exposes all visible columns of underlying object VT6 as properties, while label "weighted" has no properties.
- Vertex table VT7 defines a single label bar that exposes all columns of the underlying object VT3 but its column C3.
- Vertex table VT8 defines two labels, bar2 and VT8 (via the DEFAULT LABEL). The former has no properties while the later exposes all columns as properties.
- Vertex table VT9 defines (implicitly) a single label VT9 with two properties PX and PZ, with PX exposing an expression over columns Cx and Cy of the underlying object VT9, while PZ exposes its column Cz.
- Vertex table VT10 defines one property CREDITSCORE that extracts creditScore value as number data type from the JSON type column JCOL.
- Vertex table VT11 defines one property PURCHASEDATE that extracts purchase order date value as date data type from the XMLtype column XCOL.

graph_options

Use the OPTIONS clause to specify a comma separated list of options. Each option can appear only once. You can specify the mode of the graph, one of ENFORCED or TRUSTED. You can either allow or disallow mixed types in properties with the same name.

ENFORCED or TRUSTED Mode

Option ENFORCED on the property graph means that guarantees are enforced over the entire graph via constraints in the ENABLE VALIDATE state.

If you do not specify ENFORCED , the mode is TRUSTED. This is the default mode.

A property graph is in ENFORCED mode if :

- All of its graph element tables are defined with a primary key that matches an existing ENABLE VALIDATE primary key constraint, or a unique key constraint in the ENABLE VALIDATE state where all columns are not nullable.
- All vertex table references from edge tables are defined with a foreign key that matches an existing ENABLE VALIDATE foreign key constraint between the underlying objects for the edge and the vertex table respectively, that (foreign key constraint) defines the source or destination vertex table reference. Further, the foreign key columns must have a NOT NULL constraint, and a ENABLE VALIDATE primary key constraint, or both a unique and not null constraints, must be defined on the referenced keys for each of the source and destination table.

If neither one of these conditions is true, then the property graph is in TRUSTED mode. This is the default mode.

Example: Creation of a Property Graph in Enforced Mode

```
CREATE PROPERTY GRAPH "mygraph"
  VERTEX TABLES (VT1, VT2 KEY(PK2)),
  EDGE TABLES (
    ET1 SOURCE VT1 DESTINATION VT2,
```

```
   ET2 SOURCE KEY(FK2) REFERENCES VT2 (PK2) DESTINATION VT1)
OPTIONS(ENFORCED MODE);
```

The DDL in the example fails if any of the following is true:

- If neither a primary key constraint, or exacly one unique key constraints on non nullable columns can be found for vertex table `VT1`, edge table `ET1` or edge table `ET2`, regardless of the `ENFORCED MODE` option.
- If there is not exactly one foreign key between `ET1` and its referenced tables `VT1` and `VT2`, or between `ET2` and its referenced table `VT1`, regardless of the `ENFORCED MODE` option.
- If neither a single primary key constraint on `VT2.PK2`, or a unique key constraint and `NOT NULL` constraint on `VT2.PK2` can be found, as a result of the `ENFORCED MODE` option.
- If no foreign key constraint can be found between `ET2.FK2` and its referenced table `VT2.PK2`, and there is neither a primary key constraint, or both a unique key and a `NOT NULL` constraint on `VT2.PK2`, as a result of the `ENFORCED MODE` option.

DDL operations on constraints on tables that form the underlying objects of a property graph can invalidate the graph if this one was successfully created with the `ENFORCED MODE` option and have no effect on the graph if this one was successfully created with the `TRUSTED MODE` option.

Table 14-1 DDL Operations on Constraints that Causes Graph Created with the ENFORCED MODE Option to become Invalid

Operations	Description
`pkc` is a `PRIMARY KEY` constraint in the statements below. `ALTER TABLE t DROP CONSTRAINT pkc;`	If `t` is a graph element table `e` of `G`, and `pkc` is a primary or unique key constraint on columns used as keys for `e`, and `G` was in `ENFORCED` mode, `G` is changed to be in `TRUSTED` mode.
`ALTER TABLE t DISABLE CONSTRAINT pkc;` `ALTER TABLE t ENABLE NOVALIDATE CONSTRAINT pkc;`	If `t` is a vertex table `e` of `G` and `pkc` is a primary or unique key constraint on columns used to define a referenced key of a foreign key constraint with one or more edge tables, and `G` was in `ENFORCED` mode, `G` is changed to be in `TRUSTED` mode.

`fkc` is a `FOREIGN KEY` constraint in the statements below.
`ALTER TABLE t DROP CONSTRAINT fkc;`
`ALTER TABLE t DISABLE CONSTRAINT fkc;`
`ALTER TABLE t ENABLE NOVALIDATE CONSTRAINT fkc;`
	If `t` is an edge table `e` of `G`, and `fkc` is a foreign key constraint on columns used as source or destination keys for `e` referencing columns of vertex table `v`, and `G` was in `ENFORCED` mode, `G` is changed to be in `TRUSTED` mode

ALLOW or DISALLOW MIXED PROPERTY TYPES

`DISALLOW` means that the types of properties with same name should be exactly the same, regardless of the labels where they come. Use `DISALLOW` when you want to ensure that a given property has the same type across all labels.

`ALLOW` means that the types of properties with same name exposed in different labels can be distinct and of properties with same name coming from same label should be `UNION` compatible.

If you specify `DISALLOW MIXED PROPERTY TYPES`, the properties of a given name must have exactly the same type in every label. Note that this option also requires that you define a label associated with multiple graph element tables with the same data type.

The table summarizes the compatibility rules.

Table 14-2 Compatibility Rules for Mixed Property Types

Options	ALLOW	DISALLOW
Properties with same name in different definition of the same labels	Types must be `UNION` Compatible	Types must match
Properties with same name from different labels	Any	Types must match

`DISALLOW MIXED PROPERTY TYPES` is the default.

Dependencies Between Property Graph and its Underlying Objects

A property graph depends on the underlying objects it is based upon, tables, materialized views, or synonyms of tables or materialized views. Changes in these underlying objects can render the property graph invalid. Cursors that depend on the underlying objects are also invalidated. Queries against an invalid property graph in invalid state will error.

The following summarizes operations on dependent objects that cause a property graph to become invalid:

Table 14-3 Operations on Dependent Objects that Invalidate a Property Graph

Operations	Result

`DROP TABLE t ;`
`DROP [PUBLIC] SYNONYM t;`
`DROP MATERIALIZED VIEW t;`
`CREATE OR REPLACE [PUBLIC] SYNONYM t;`
	If `t` is used to define a graph element table *e* of graph `G`, then `G` becomes invalid.

`RENAME t TO t2;`	If `t` is used to defined a graph element table *e* of graph `G`, then `G` becomes invalid
`ALTER TABLE` for dropping an unused column `C` of table `t` `ALTER TABLE`	If `t` is used to defined a graph element table *e* of graph `G`, then `G` becomes invalid
`ALTER TABLE t RENAME C TO C2;`	If `t` is used to defined a graph element table *e* of graph `G` and at least one label applied to *e* define a property as an SQL operator expression, then `G` becomes invalid
`ALTER TABLE` for modifying the type of a column `C` of table `t`	If `t` is used to defined a graph element table *e* of graph `G`, then `G` becomes invalid

Other DDL operations to alter dependent tables, views, or synonyms do not invaliate the property graph.

Note also that using a materialized view to define vertex or edge tables in a property graph creates a dependency to the container table for the view, not directly to the materialized view schema object. This has the following implications:

- When dropping a materialized view but preserving its table (i.e., using `PRESERVE TABLE`), the property graph remains valid.
- When dropping one of the tables, views, or synonyms used in the definition of the materialized view, the materialized view becomes invalid, but the property graph remains valid as it only depends on the container table.

This behavior is similar to the behavior of views defined over a materialized view.

Revalidating a Property Graph

Changes to the underlying objects of a property graph may invalidate the graph. An invalid state indicates that the metadata of the property graph describes an incorrect definition with respect to the property graph data model.

You can revalidate the property graph by redefining it with `CREATE OR REPLACE PROPERTY GRAPH` .

Sometimes however a graph may report an invalid state when it is actually valid. This can happen when the dependencies of the graph to its underlying objects are too coarse. When this happens you can revalidate the graph using `ALTER PROPERTY GRAPH COMPILE` instead of redefining it.

> **See Also:**
>
> ALTER PROPERTY GRAPH

Examples

Example: Property Graph Without Explicit Labels or Properties

In the example a property graph `myGraph` is created without labels or properties. A label with name `mytable` is automatically associated with the vertex table `mytable` defined over the object `myschema`. A label with name `T2` is automatically associated with the vertex table `T2` defined over the object `mytable2`.

All the columns of the underlying tables `mytable` and `T2` are exposed as properties. The property name is the column name.

```
CREATE PROPERTY GRAPH “myGraph”
      VERTEX TABLES (“myschema”. “mytable”, “mytable2” AS T2);
```

Example: Property Graph With An Explicit Label

In the example the vertex table `mytable` is associated with the label `person`.

All the columns of `mytable` are exposed as properties.

```
CREATE PROPERTY GRAPH “myGraph”
     VERTEX TABLES (“myschema”. “mytable” LABEL “person”);
```

If a label with the name of the graph element table is also needed, you have to explicitly declare it in addition to the `person` label. You can do this by declaring another explicit label that has the name of the graph element table, or by adding a `DEFAULT LABEL`.

The following vertex table declarations are semantically equivalent and all associate the graph element table `mytable` with the label `mytable`:

```
CREATE PROPERTY GRAPH "myGraph"
  VERTEX TABLES ("myschema". "mytable" LABEL "mytable");

CREATE PROPERTY GRAPH
  VERTEX TABLES ("myschema". "mytable" DEFAULT LABEL);

CREATE PROPERTY GRAPH
  VERTEX TABLES ("myschema". "mytable" AS "mytable");

CREATE PROPERTY GRAPH
  VERTEX TABLES ("myschema". "mytable");
```

Example: Property Graph With Multipe Labels

You can associate multiple labels to the same graph element. The example vertex table `mytable` is associated with two labels `foo` and `bar`.

All the columns of `mytable` are exposed as properties.

```
CREATE PROPERTY GRAPH "myGraph"
  VERTEX TABLES ("myschema". "mytable" LABEL "foo" LABEL "bar");
```

Example: Property Graph With One Label Associating Multiple Graph Elements

The example shows a property graph `mygraph` where the shared `weighted` label associates two vertex tables `mytable1` and `mytable2` and two edge tables `E1` and `E2` .

All the columns of `mytable1` and `mytable2`are exposed as properties.

```
CREATE PROPERTY GRAPH "myGraph"
    VERTEX TABLES (
      "mytable1" LABEL "foo" LABEL "weighted",
      "mytable2" LABEL "weighted"),
    EDGE TABLES (
      "E1" SOURCE  "mytable1" DESTINATION "mytable2" LABEL "weighted"
      "E2" SOURCE  "mytable2" DESTINATION "mytable1" LABEL "weighted"
  );
```

CREATE RESTORE POINT

Purpose

Use the `CREATE RESTORE POINT` statement to create a **restore point**, which is a name associated with a timestamp or an SCN of the database. A restore point can be used to flash back a table or the database to the time specified by the restore point without the need to determine the SCN or timestamp. Restore points are also useful in various RMAN operations, including backups and database duplication. You can use RMAN to create restore points in the process of implementing an archival backup.

See Also:

- *Oracle Database Backup and Recovery User's Guide* for more information on creating and using restore points and guaranteed restore points, for information on database duplication, and for information on archival backups
- FLASHBACK DATABASE, FLASHBACK TABLE , and DROP RESTORE POINT for information on using and dropping restore points

Prerequisites

To create a normal restore point, you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege.

To create a guaranteed restore point, you must fulfill *one* of the following conditions:

- You must connect AS SYSDBA, or AS SYSBACKUP, or AS SYSDG.
- You must have been granted the SYSDBA privilege and be using a multitenant database.
- You must be running as user SYS, and be using a a multitenant database.

To view or use a restore point, you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege or the SELECT_CATALOG_ROLE role.

You can create a restore point on a primary or standby database. The database can be open, or mounted but not open. If the database is mounted, then it must have been shut down consistently before being mounted unless it is a physical standby database.

You must have created a fast recovery area before creating a guaranteed restore point. You need not enable flashback database before you create the guaranteed restore point. The database must be in ARCHIVELOG mode if you are creating a guaranteed restore point.

You need not enable flashback database before you create a normal restore point, because normal restore points have other applications besides FLASHBACK DATABASE. However, you would need to have enabled flashback database before you create a normal restore point, if you intend to perform a FLASHBACK DATABASE to that normal restore point.

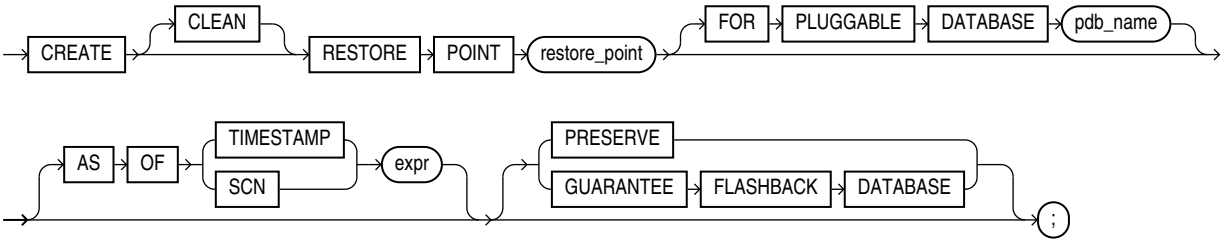
You can create, use, or view a restore point when connected to a multitenant container database (CDB) as follows:

- To create a normal CDB restore point, the current container must be the root and you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly.
- To create a guaranteed CDB restore point, the current container must be the root and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly.
- To view a CDB restore point, the current container must be the root and you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege or the SELECT_CATALOG_ROLE role, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly, or the current container must be a PDB and you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.
- To use a CDB restore point, you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege or the SELECT_CATALOG_ROLE role, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly.
- To create a normal PDB restore point, the current container must be the root and you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly, or the current container must be the PDB for which you want to create the restore point and you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.

- To create a guaranteed PDB restore point, the current container must be the root and you must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly, or the current container must be the PDB for which you want to create the restore point and you must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly .
- To view a PDB restore point, the current container must be the root and you must have the `SELECT ANY DICTIONARY` or `FLASHBACK ANY TABLE` system privilege or the `SELECT_CATALOG_ROLE` role, either granted commonly or granted locally in the root, or the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege granted commonly, or the current container must be the PDB for the restore point and you must have the `SELECT ANY DICTIONARY`, `FLASHBACK ANY TABLE`, `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly or granted locally in that PDB.
- To use a PDB restore point, the current container must be the PDB for the restore point and you must have the `SELECT ANY DICTIONARY`, `FLASHBACK ANY TABLE`, `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly or granted locally in that PDB.

Syntax

***create_restore_point*::=**



Semantics

CLEAN

You can specify `CLEAN` only when creating a PDB restore point. The PDB must use shared undo and must be closed with no outstanding transactions. Flashing back a PDB using shared undo to a clean PDB restore point does not require restoring backups or creating a clone instance. Therefore, it is faster than flashing back a PDB using shared undo to an SCN or other type of restore point.

restore_point

Specify the name of the restore point. The name must satisfy the requirements listed in "Database Object Naming Rules ".

In a multitenant environment, the CDB and PDBs have their own namespaces for restore points. Therefore, the CDB and each PDB can have a restore point with the same name. When you specify a restore point name in a PDB or for a PDB operation, the name is first interpreted as a PDB restore point for the concerned PDB. If a PDB restore point with the specified name is not found, then it is interpreted as a CDB restore point.

The database can retain at least 2048 normal restore points. In a Multitenant environment, a CDB can retain at least 2048 normal restore points across the entire CDB, including PDB restore points. Normal restore points are retained in the database for at least the number of days specified for the `CONTROL_FILE_RECORD_KEEP_TIME` initialization parameter. The default value of that parameter is 7 days. Guaranteed restore points are retained in the database until explicitly dropped by the user.

If you specify neither PRESERVE nor GUARANTEE FLASHBACK DATABASE, then the resulting restore point enables you to flash the database back to a restore point within the time period determined by the DB_FLASHBACK_RETENTION_TARGET initialization parameter. The database automatically manages such restore points. When the maximum number of restore points is reached, according to the rules described in *restore_point* above, the database automatically drops the oldest restore point. Under some circumstances the restore points will be retained in the RMAN recovery catalog for use in restoring long-term backups. You can explicitly drop a restore point using the DROP RESTORE POINT statement.

FOR PLUGGABLE DATABASE

This clause enables you to create a PDB restore point when you are connected to the root. For *pdb_name*, specify the name of the PDB.

If you are connected to the PDB for which you want to create the restore point, then it is not necessary to specify this clause. However, if you specify this clause, then you must specify the name of the PDB to which you are connected.

AS OF Clause

Use this clause to create a restore point at a specified datetime or SCN in the past. If you specify TIMESTAMP, then *expr* must be a valid datetime expression resolving to a time in the past. If you specify SCN, then *expr* must be a valid SCN in the database in the past. In either case, *expr* must refer to a datetime or SCN in the current incarnation of the database.

PRESERVE

Specify PRESERVE to indicate that the restore point must be explicitly deleted. Such restore points are useful for preserving a flashback database.

GUARANTEE FLASHBACK DATABASE

A guaranteed restore point enables you to flash the database back deterministically to the restore point regardless of the DB_FLASHBACK_RETENTION_TARGET initialization parameter setting. The guaranteed ability to flash back depends on sufficient space being available in the fast recovery area.

Guaranteed restore points guarantee only that the database will maintain enough flashback logs to flashback the database to the guaranteed restore point. It does not guarantee that the database will have enough undo to flashback any table to the same restore point.

Guaranteed restore points are always preserved. They must be dropped explicitly by the user using the DROP RESTORE POINT statement. They do not age out. Guaranteed restore points can use considerable space in the fast recovery area. Therefore, Oracle recommends that you create guaranteed restore points only after careful consideration.

Examples

Creating and Using a Restore Point: Example

The following example creates a normal restore point, updates a table, and then flashes back the altered table to the restore point. The example assumes the user hr has the appropriate system privileges to use each of the statements.

```
CREATE RESTORE POINT good_data;

SELECT salary FROM employees WHERE employee_id = 108;

    SALARY
```

```
----------
     12000

UPDATE employees SET salary = salary*10
   WHERE employee_id = 108;

SELECT salary FROM employees
   WHERE employee_id = 108;

    SALARY
----------
    120000

COMMIT;

FLASHBACK TABLE employees TO RESTORE POINT good_data;

SELECT salary FROM employees
   WHERE employee_id = 108;

    SALARY
----------
     12000
```

CREATE ROLE

Purpose

Use the `CREATE ROLE` statement to create a **role**, which is a set of privileges that can be granted to users or to other roles. You can use roles to administer database privileges. You can add privileges to a role and then grant the role to a user. The user can then enable the role and exercise the privileges granted by the role.

A role contains all privileges granted to the role and all privileges of other roles granted to it. A new role is initially empty. You add privileges to a role with the `GRANT` statement.

If you create a role that is `NOT IDENTIFIED` or is `IDENTIFIED EXTERNALLY` or `BY` *`password`*, then Oracle Database grants you the role with `ADMIN OPTION`. However, if you create a role `IDENTIFIED GLOBALLY`, then the database does not grant you the role. A global role cannot be granted to a user or role directly. Global roles can be granted through EUS enterprise roles, mapped group memberships, and mapped app roles.

See Also:

- GRANT for information on granting roles
- ALTER USER for information on enabling roles
- ALTER ROLE and DROP ROLE for information on modifying or removing a role from the database
- SET ROLE for information on enabling and disabling roles for the current session
- *Oracle Database Security Guide* for general information about roles
- *Oracle Database Enterprise User Security Administrator's Guide* for details on enterprise roles

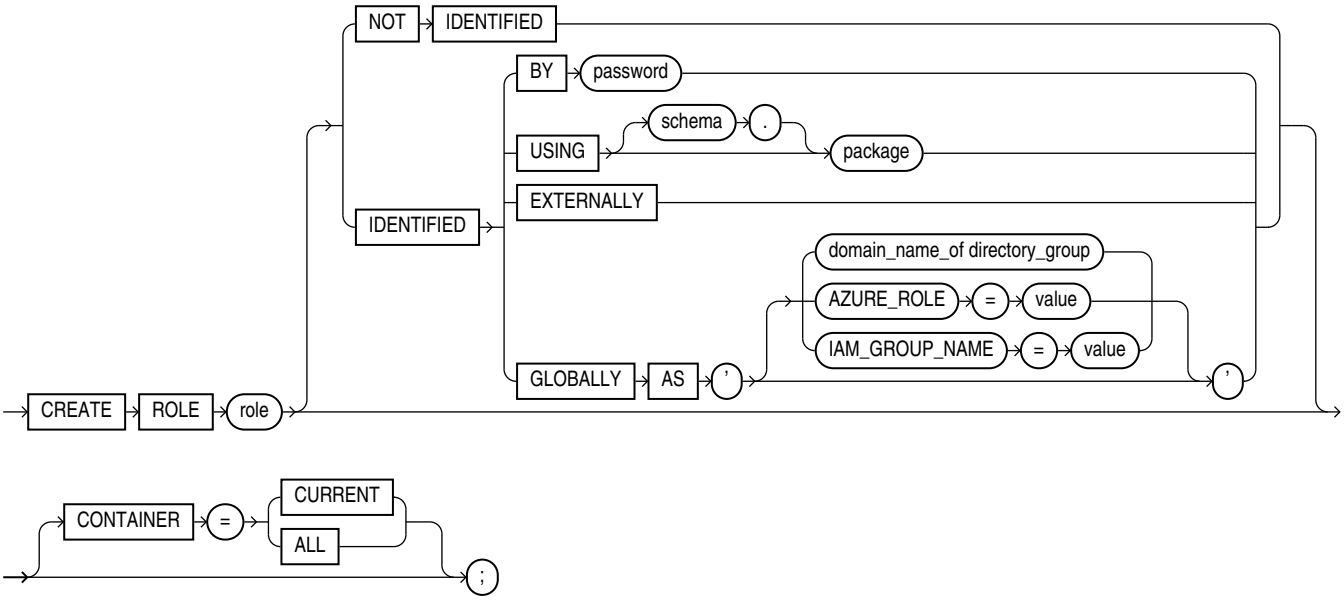
Prerequisites

You must have the `CREATE ROLE` system privilege.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

Syntax

***create_role*::=**



Semantics

role

Specify the name of the role to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ". Oracle recommends that the role contain at least one single-byte character regardless of whether the database character set also contains multibyte characters. The maximum length of the role name is 128 bytes. The maximum number of user-defined roles that can be enabled for a single user at one time is 148.

In a non-CDB, a role name cannot begin with `C##` or `c##`.

> **Note:**
>
> A multitenant container database is the only supported architecture in Oracle Database 21c and later releases. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

In a CDB, the requirements for a role name are as follows:

- The name of a **common role** must begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, the prefix is `C##`.
- The name of a **local role** must not begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. Regardless of the value of `COMMON_USER_PREFIX`, the name of a local role can never begin with `C##` or `c##`.

> **Note:**
>
> If the value of `COMMON_USER_PREFIX` is an empty string, then there are no requirements for common or local role names with one exception: the name of a local role can never begin with `C##` or `c##`. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common roles when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

Some roles are defined by SQL scripts provided on your distribution media.

> **See Also:**
>
> GRANT for a list of these predefined roles and SET ROLE for information on enabling and disabling roles for a user

NOT IDENTIFIED Clause

Specify `NOT IDENTIFIED` to indicate that this role is authorized by the database and that no password is required to enable the role.

IDENTIFIED Clause

Use the `IDENTIFIED` clause to indicate that a user must be authorized by the specified method before the role is enabled with the `SET ROLE` statement.

BY *password*

You can create a **local role** with a password with the `BY` *`password`* clause. This means that you must specify the password to the database at the time you enable the role.

The password can contain any characters from the database character set except the `NULL` character `(CHR(0))` and the double-quote. The maximum length of the password is 1024 bytes. The password is syntactically an identifier, and may need to be enclosed in double-quotes as required by the "Database Object Naming Rules ". You must ensure that your database, and the clients that need to enable the role are configured to support all the characters comprising the password.

You can enable password-protected roles in a proxy session. Both secure application role and password-protected roles provide a secure method for enabling a role in a session. Oracle recommends using secure password roles instead of password protected roles in instances where the password has to be maintained and transmitted over insecure channels, or if more than one person needs to know the password. Password-protected roles in a proxy session are suitable for situations where automation is used to set the role.

USING *package*

The `USING package` clause lets you create a **secure application role**, which is a role that can be enabled only by applications using an authorized package. If you do not specify *schema*, then the database assumes the package is in your own schema.

> **See Also:**
>
> *Oracle Database Security Guide* for information on creating a secure application role

EXTERNALLY

Specify `EXTERNALLY` to create an **external role.** An external user must be authorized by an external service, such as an operating system or third-party service, before enabling the role.

Depending on the operating system, the user may have to specify a password to the operating system before the role is enabled.

GLOBALLY

Specify `GLOBALLY` to create a **global role** . A global user must be authorized to use the role by the enterprise directory service before the role is enabled at login.

Specify `GLOBALLY` with `AS` to map a directory group to a global role when using centrally managed users. The directory group is identified by its domain name.

Example: Map a Directory User to a Global User

```
  CREATE USER scott_global IDENTIFIED GLOBALLY AS 'cn=scott
taylor,ou=sales,dc=abccorp,dc=com';
```

This effectively maps a directory user named ‘scott taylor’ in the ‘sales’ organization unit of the abccorp.com domain to a database global user ‘scott_global’.

You can map an Oracle Database global role to an Azure app role in order to give Azure users and applications additional privileges and roles beyond those that they have through their login schemas.

Example: Map an Oracle Database Global Role to an App Role

The example creates a new database global role *widget_sales_role* and maps it to an existing Azure AD application role *WidgetManagerGroup*:

```
CREATE ROLE widget_sales_role IDENTIFIED GLOBALLY AS 'AZURE_ROLE=WidgetManagerGroup';
```

> **See Also:**
>
> *Authenticating and Authorizing Microsoft Azure Active Directory Users for Oracle Autonomous Databases*

CONTAINER Clause

The `CONTAINER` clause applies when you are connected to a CDB. However, it is not necessary to specify the `CONTAINER` clause because its default values are the only allowed values.

- To create a common role, you must be connected to the root. You can optionally specify `CONTAINER = ALL`, which is the default when you are connected to the root.
- To create a local role, you must be connected to a PDB. You can optionally specify `CONTAINER = CURRENT`, which is the default when you are connected to a PDB.

Examples

Creating a Role: Example

The following statement creates the role `dw_manager`:

```
CREATE ROLE dw_manager;
```

Users who are subsequently granted the `dw_manager` role will inherit all of the privileges that have been granted to this role.

You can add a layer of security to roles by specifying a password, as in the following example:

```
CREATE ROLE dw_manager
   IDENTIFIED BY warehouse;
```

Users who are subsequently granted the `dw_manager` role must specify the password `warehouse` to enable the role with the `SET ROLE` statement.

The following statement creates global role `warehouse_user`:

```
CREATE ROLE warehouse_user IDENTIFIED GLOBALLY;
```

The following statement creates the same role as an external role:

```
CREATE ROLE warehouse_user IDENTIFIED EXTERNALLY;
```

The following statement creates local role `role1` in the current PDB. The current container must be a PDB when you issue this statement:

```
CREATE ROLE role1 CONTAINER = CURRENT;
```

The following statement creates common role `c##role1`. The current container must be the root when you issue this statement:

```
CREATE ROLE c##role1 CONTAINER = ALL;
```

CREATE ROLLBACK SEGMENT

> **Note:**
>
> Oracle strongly recommends that you run your database in automatic undo management mode instead of using rollback segments. Do not use rollback segments unless you must do so for compatibility with earlier versions of Oracle Database. Refer to *Oracle Database Administrator's Guide* for information on automatic undo management.

Purpose

Use the `CREATE ROLLBACK SEGMENT` statement to create a **rollback segment**, which is an object that Oracle Database uses to store data necessary to reverse, or undo, changes made by transactions.

The information in this section assumes that your database is not running in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `MANUAL` or not set at all). If your database is running in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `AUTO`, which is the default), then rollback segments are not permitted. However, errors generated in rollback segment operations are suppressed.

Further, if your database has a locally managed `SYSTEM` tablespace, then you cannot create rollback segments in any dictionary-managed tablespace. Instead, you must either use the automatic undo management feature or create locally managed tablespaces to hold the rollback segments.

> **Note:**
>
> A tablespace can have multiple rollback segments. Generally, multiple rollback segments improve performance.
>
> - The tablespace must be online for you to add a rollback segment to it.
> - When you create a rollback segment, it is initially offline. To make it available for transactions by your Oracle Database instance, bring it online using the `ALTER ROLLBACK SEGMENT` statement. To bring it online automatically whenever you start up the database, add the segment name to the value of the `ROLLBACK_SEGMENT` initialization parameter.

To use objects in a tablespace other than the `SYSTEM` tablespace:

- If you are using rollback segments for undo, then at least one rollback segment (other than the `SYSTEM` rollback segment) must be online.
- If you are running the database in automatic undo mode, then at least one `UNDO` tablespace must be online.

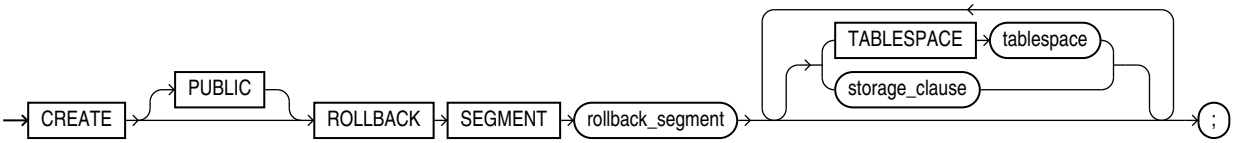
> **See Also:**
>
> - ALTER ROLLBACK SEGMENT for information on altering a rollback segment
> - DROP ROLLBACK SEGMENT for information on removing a rollback segment
> - *Oracle Database Reference* for information on the `UNDO_MANAGEMENT` parameter
> - *Oracle Database Administrator's Guide* for information on automatic undo mode

Prerequisites

To create a rollback segment, you must have the `CREATE ROLLBACK SEGMENT` system privilege.

Syntax

***create_rollback_segment*::=**



(*storage_clause*)

Semantics

PUBLIC

Specify `PUBLIC` to indicate that the rollback segment is public and is available to any instance. If you omit this clause, then the rollback segment is private and is available only to the instance naming it in its initialization parameter `ROLLBACK_SEGMENTS`.

rollback_segment

Specify the name of the rollback segment to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

TABLESPACE

Use the `TABLESPACE` clause to identify the tablespace in which the rollback segment is created. If you omit this clause, then the database creates the rollback segment in the `SYSTEM` tablespace.

> **Note:**
>
> Oracle Database must access rollback segments frequently. Therefore, Oracle strongly recommends that you do not create rollback segments in the `SYSTEM` tablespace, either explicitly or implicitly by omitting this clause. In addition, to avoid high contention for the tablespace containing the rollback segment, it should not contain other objects such as tables and indexes, and it should require minimal extent allocation and deallocation.
>
> To achieve these goals, create rollback segments in locally managed tablespaces with autoallocation disabled—in tablespaces created with the `EXTENT MANAGEMENT LOCAL` clause with the `UNIFORM` setting. The `AUTOALLOCATE` setting is not supported.

> **See Also:**
>
> CREATE TABLESPACE

storage_clause

The *storage_clause* lets you specify storage characteristics for the rollback segment.

- The `OPTIMAL` parameter of the *`storage_clause`* is of particular interest, because it applies only to rollback segments.
- You cannot specify the `PCTINCREASE` parameter of the *`storage_clause`* with `CREATE ROLLBACK SEGMENT`.

> **See Also:**
>
> *storage_clause*

Examples

Creating a Rollback Segment: Example

The following statement creates a rollback segment with default storage values in an appropriately configured tablespace:

```
CREATE TABLESPACE rbs_ts
   DATAFILE 'rbs01.dbf' SIZE 10M
   EXTENT MANAGEMENT LOCAL UNIFORM SIZE 100K;

/* This example and the next will fail if your database is in
   automatic undo mode.
*/
CREATE ROLLBACK SEGMENT rbs_one
   TABLESPACE rbs_ts;
```

The preceding statement is equivalent to the following:

```
CREATE ROLLBACK SEGMENT rbs_one
   TABLESPACE rbs_ts
   STORAGE
   ( INITIAL 10K );
```

CREATE SCHEMA

Purpose

Use the `CREATE SCHEMA` statement to create multiple tables and views and perform multiple grants in your own schema in a single transaction.

To execute a `CREATE SCHEMA` statement, Oracle Database executes each included statement. If all statements execute successfully, then the database commits the transaction. If any statement results in an error, then the database rolls back all the statements.

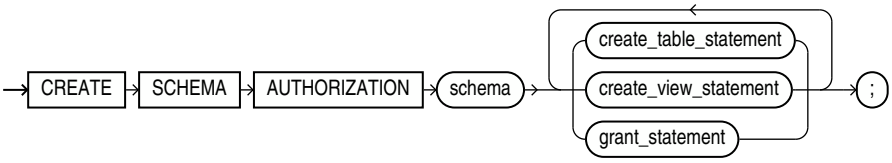
> **Note:**
>
> This statement does not actually create a schema. Oracle Database automatically creates a schema when you create a user (see CREATE USER). This statement lets you populate your schema with tables and views and grant privileges on those objects without having to issue multiple SQL statements in multiple transactions.

Prerequisites

The `CREATE SCHEMA` statement can include `CREATE TABLE`, `CREATE VIEW`, and `GRANT` statements. To issue a `CREATE SCHEMA` statement, you must have the privileges necessary to issue the included statements.

Syntax

***create_schema*::=**



Semantics

schema

Specify the name of the schema. The schema name must be the same as your Oracle Database username.

Restrictions

While `CREATE SCHEMA` supports `CREATE TABLE` , `CREATE BLOCKCHAIN TABLE` is unsupported.

create_table_statement

Specify a `CREATE TABLE` statement to be issued as part of this `CREATE SCHEMA` statement. Do not end this statement with a semicolon (or other terminator character).

> **See Also:**
>
> CREATE TABLE

create_view_statement

Specify a `CREATE VIEW` statement to be issued as part of this `CREATE SCHEMA` statement. Do not end this statement with a semicolon (or other terminator character).

> **See Also:**
>
> CREATE VIEW

grant_statement

Specify a `GRANT` statement to be issued as part of this `CREATE SCHEMA` statement. Do not end this statement with a semicolon (or other terminator character). You can use this clause to grant object privileges on objects you own to other users. You can also grant system privileges to other users if you were granted those privileges `WITH ADMIN OPTION`.

> **See Also:**
>
> GRANT

The `CREATE SCHEMA` statement supports the syntax of these statements only as defined by standard SQL, rather than the complete syntax supported by Oracle Database.

The order in which you list the `CREATE TABLE`, `CREATE VIEW`, and `GRANT` statements is unimportant. The statements within a `CREATE SCHEMA` statement can reference existing objects or objects you create in other statements within the same `CREATE SCHEMA` statement.

Restriction on Granting Privileges to a Schema

The syntax of the *parallel_clause* is allowed for a `CREATE TABLE` statement in `CREATE SCHEMA`, but parallelism is not used when creating the objects.

> **See Also:**
>
> The *parallel_clause* in the `CREATE TABLE` documentation

Examples

Creating a Schema: Example

The following statement creates a schema named `oe` for the sample order entry user `oe`, creates the table `new_product`, creates the view `new_product_view`, and grants the `SELECT` object privilege on `new_product_view` to the sample human resources user `hr`.

```
CREATE SCHEMA AUTHORIZATION oe
   CREATE TABLE new_product
      (color VARCHAR2(10)  PRIMARY KEY, quantity NUMBER)
   CREATE VIEW new_product_view
      AS SELECT color, quantity FROM new_product WHERE color = 'RED'
   GRANT select ON new_product_view TO hr;
```

15

SQL Statements: CREATE SEQUENCE to DROP CLUSTER

This chapter contains the following SQL statements:

- CREATE SEQUENCE
- CREATE SPFILE
- CREATE SYNONYM
- CREATE TABLE
- CREATE TABLESPACE
- CREATE TABLESPACE SET
- CREATE TRIGGER
- CREATE TYPE
- CREATE TYPE BODY
- CREATE USER
- CREATE VECTOR INDEX
- CREATE VIEW
- DELETE
- DISASSOCIATE STATISTICS
- DROP ANALYTIC VIEW
- DROP ATTRIBUTE DIMENSION
- DROP AUDIT POLICY (Unified Auditing)
- DROP CLUSTER

CREATE SEQUENCE

Purpose

A sequence is a database object used to produce unique integers, which are commonly used to populate a synthetic primary key column in a table. The sequence number always increases, typically by 1, and each new entry is placed on the right-most leaf block of the index.

Use the `CREATE SEQUENCE` statement to create a sequence to automatically generate primary key values.

When a sequence number is generated, the sequence is incremented, independent of the transaction committing or rolling back. If two users concurrently increment the same sequence, then the sequence numbers each user acquires may have gaps, because sequence numbers are being generated by the other user. One user can never acquire the sequence number generated by another user. After a sequence value is generated by one user, that user can

continue to access that value regardless of whether the sequence is incremented by another user.

Sequence numbers are generated independently of tables, so the same sequence can be used for one or for multiple tables. It is possible that individual sequence numbers will appear to be skipped, because they were generated and used in a transaction that ultimately rolled back. Additionally, a single user may not realize that other users are drawing from the same sequence.

After a sequence is created, you can access its values in SQL statements with the `CURRVAL` pseudocolumn, which returns the current value of the sequence, or the `NEXTVAL` pseudocolumn, which increments the sequence and returns the new value.

See Also:

- Pseudocolumns for more information on using the `CURRVAL` and `NEXTVAL`
- "How to Use Sequence Values " for information on using sequences
- ALTER SEQUENCE or DROP SEQUENCE for information on modifying or dropping a sequence

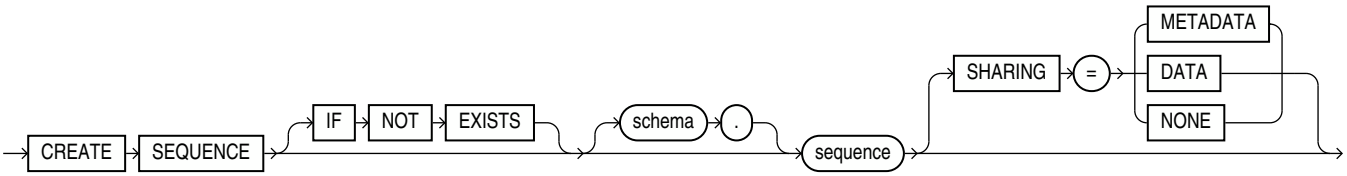
Prerequisites

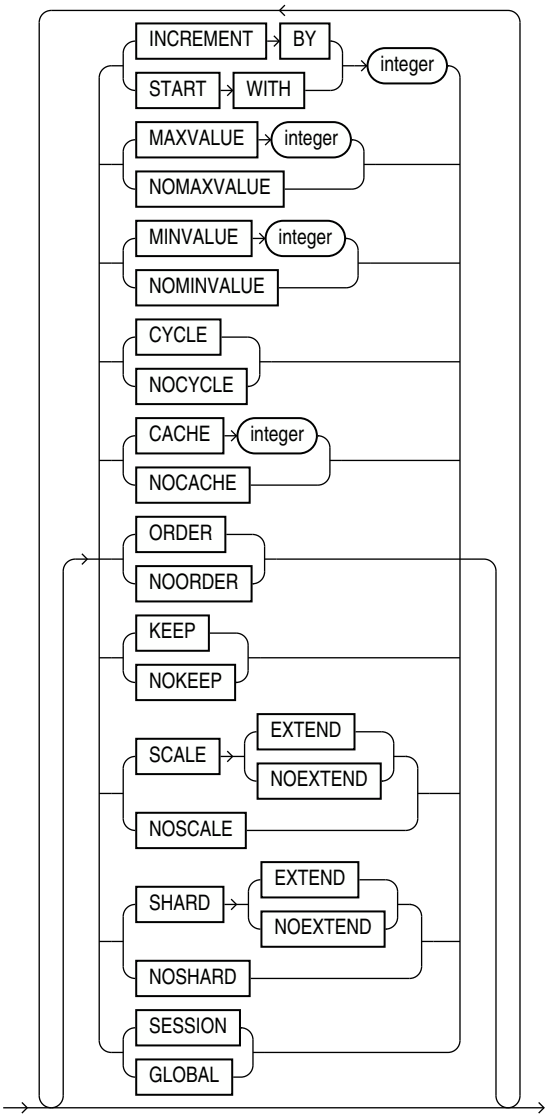
To create a sequence in your own schema, you must have the `CREATE SEQUENCE` system privilege.

To create a sequence in another user's schema, you must have the `CREATE ANY SEQUENCE` system privilege.

Syntax

***create_sequence*::=**





Semantics

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the sequence does not exist, a new sequence is created at the end of the statement.

- If the sequence exists, this is the sequence you have at the end of the statement. A new one is not created because the older one is detected.

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement`.

schema

Specify the schema to contain the sequence. If you omit *`schema`*, then Oracle Database creates the sequence in your own schema.

sequence

Specify the name of the sequence to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

If you specify none of the clauses `INCREMENT BY` through `GLOBAL`, then you create an ascending sequence that starts with 1 and increases by 1 with no upper limit. Specifying only `INCREMENT BY` -1 creates a descending sequence that starts with -1 and decreases with no lower limit.

- To create a sequence that increments without bound, for ascending sequences, omit the `MAXVALUE` parameter or specify `NOMAXVALUE`. For descending sequences, omit the `MINVALUE` parameter or specify the `NOMINVALUE`.
- To create a sequence that stops at a predefined limit, for an ascending sequence, specify a value for the `MAXVALUE` parameter. For a descending sequence, specify a value for the `MINVALUE` parameter. Also specify `NOCYCLE`. Any attempt to generate a sequence number once the sequence has reached its limit results in an error.
- To create a sequence that restarts after reaching a predefined limit, specify values for both the `MAXVALUE` and `MINVALUE` parameters. Also specify `CYCLE`.

SHARING

This clause applies only when creating a sequence in an application root. This type of sequence is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the sequence is shared, specify one of the following sharing attributes:

- `METADATA` - A metadata link shares the sequence's metadata, but its data is unique to each container. This type of sequence is referred to as a **metadata-linked application common object**.
- `DATA` - A data link shares the sequence, and its data is the same for all containers in the application container. Its data is stored only in the application root. This type of sequence is referred to as a **data-linked application common object**.
- `NONE` - The sequence is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the sequence. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

You cannot change the sharing attribute of a sequence after it is created.

> **See Also:**
>
> - *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
> - *Oracle Database Administrator's Guide* for complete information on creating application common objects

INCREMENT BY

Specify the interval between sequence numbers. This integer value can be any positive or negative integer, but it cannot be 0. This value can have 28 or fewer digits for an ascending sequence and 27 or fewer digits for a descending sequence. The absolute of this value must be less than the difference of `MAXVALUE` and `MINVALUE`. If this value is negative, then the sequence descends. If the value is positive, then the sequence ascends. If you omit this clause, then the interval defaults to 1.

START WITH

Specify the first sequence number to be generated. Use this clause to start an ascending sequence at a value greater than its minimum or to start a descending sequence at a value less than its maximum. For ascending sequences, the default value is the minimum value of the sequence. For descending sequences, the default value is the maximum value of the sequence. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values.

> **Note:**
>
> This value is not necessarily the value to which an ascending or descending cycling sequence cycles after reaching its maximum or minimum value, respectively.

MAXVALUE

Specify the maximum value the sequence can generate. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values. `MAXVALUE` must be equal to or greater than `START WITH` and must be greater than `MINVALUE`.

NOMAXVALUE

Specify `NOMAXVALUE` to indicate a maximum value of 10^{28}-1 for an ascending sequence or -1 for a descending sequence. This is the default.

MINVALUE

Specify the minimum value of the sequence. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values. `MINVALUE` must be less than or equal to `START WITH` and must be less than `MAXVALUE`.

NOMINVALUE

Specify `NOMINVALUE` to indicate a minimum value of 1 for an ascending sequence or -(10^{27} -1) for a descending sequence. This is the default.

CYCLE

Specify `CYCLE` to indicate that the sequence continues to generate values after reaching either its maximum or minimum value. After an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum, it generates its maximum value.

NOCYCLE

Specify `NOCYCLE` to indicate that the sequence cannot generate more values after reaching its maximum or minimum value. This is the default.

CACHE

Specify how many values of the sequence the database preallocates and keeps in memory for faster access. This integer value can have 28 or fewer digits. The minimum value for this parameter is 2. For sequences that cycle, this value must be less than the number of values in the cycle. You cannot cache more values than will fit in a given cycle of sequence numbers. Therefore, the maximum value allowed for `CACHE` must be less than the value determined by the following formula:

```
CEIL ( (MAXVALUE - MINVALUE) / ABS (INCREMENT) )
```

If a system failure occurs, then all cached sequence values that have not been used in committed DML statements are lost. The potential number of lost values is equal to the value of the `CACHE` parameter.

> **Note:**
>
> Oracle recommends using the `CACHE` setting to enhance performance if you are using sequences in an Oracle Real Application Clusters environment.

NOCACHE

Specify `NOCACHE` to indicate that values of the sequence are not preallocated. If you omit both `CACHE` and `NOCACHE`, then the database caches 20 sequence numbers by default.

ORDER

Specify `ORDER` to guarantee that sequence numbers are generated in order of request. This clause is useful if you are using the sequence numbers as timestamps. Guaranteeing order is usually not important for sequences used to generate primary keys.

NOORDER

Specify `NOORDER` if you do not want to guarantee sequence numbers are generated in order of request. This is the default.

KEEP

Specify `KEEP` if you want `NEXTVAL` to retain its original value during replay for Application Continuity. This behavior will occur only if the user running the application is the owner of the schema containing the sequence. This clause is useful for providing bind variable consistency at replay after recoverable errors. Refer to *Oracle Database Development Guide* for more information on Application Continuity.

NOKEEP

Specify `NOKEEP` if you do not want `NEXTVAL` to retain its original value during replay for Application Continuity. This is the default.

> **Note:**
>
> The `KEEP` and `NOKEEP` clauses apply only to the owner of the schema containing the sequence. You can control whether `NEXTVAL` retains its original value for other users during replay for Application Continuity by granting or revoking the `KEEP SEQUENCE` object privilege on the sequence. Refer to Table 18-4 for more information on the `KEEP SEQUENCE` object privilege.

SCALE

Use `SCALE` to create a scalable sequence. A scalable sequence adds a 5 digit prefix to the sequence. The prefix is made up of a 2 digit instance offset concatenated to a 3 digit session offset as follows:

```
[(instance id % 100) ] || [session id % 1000]
```

The final sequence number is in the format `prefix || zero-padding || sequence`, where the amount of padding depends on the maximum width of the sequence.

Prior to Release 23, a scalable sequence would have a leading "1" as part of the instance offset:

```
SELECT mysequence.nextval FROM DUAL;

NEXTVAL
----------
101213001
```

In Release 23, this same scalable sequence will have the leading "1" of the instance offset removed:

```
SELECT mysequence.nextval FROM DUAL;

NEXTVAL
----------
1213001
```

> **Note:**
>
> Starting with Oracle Database Release 23 any newly created scalable sequences will have the leading "1" of the instance offset removed. Scalable sequences created prior to Release 23 will retain the leading '1' of the instance offset.

When you use `SCALE` it is highly recommended that you not use `ORDER` simultaneously on the sequence.

EXTEND

Specifying `EXTEND` with `SCALE` causes the sequence number to be left padded with zeros to its maximum length, then the prefix concatenated, so the final sequence number has 6 more digits than the `MAXVALUE` setting.

NOEXTEND

The default setting for the `SCALE` clause is `NOEXTEND`. With the `NOEXTEND` setting, the generated sequence values are at most as wide as the maximum number of digits in the sequence `MAXVALUE` setting.

`NOEXTEND` is the default setting for the `SCALE` clause. With the `NOEXTEND` setting, the generated sequence values are at most as wide as the maximum number of digits in the sequence `(maxvalue/minvalue)`. This setting is useful for integration with existing applications where sequences are used to populate fixed width columns.

NOSCALE

The default attribute for a sequence is `NOSCALE`, but you can also specify it explicitly to disable sequence scalability..

SHARD

For complete semantics on the `SHARD` clause please refer to the `SHARD` clause of the ALTER SEQUENCE statement.

SESSION

Specify `SESSION` to create a session sequence, which is a special type of sequence that is specifically designed to be used with global temporary tables that have session visibility. Unlike the existing regular sequences (referred to as "global" sequences for the sake of comparison), a session sequence returns a unique range of sequence numbers only within a session, but not across sessions. Another difference is that session sequences are not persistent. If a session goes away, so does the state of the session sequences that were accessed during the session.

Session sequences must be created by a read-write database but can be accessed on any read-write or read-only databases (either a regular database temporarily open read-only or a standby database).

The `CACHE`, `NOCACHE`, `ORDER`, or `NOORDER` clauses are ignored when specified with the `SESSION` clause.

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information on session sequences

GLOBAL

Specify `GLOBAL` to create a global, or regular, sequence. This is the default.

Examples

Creating a Sequence: Example

The following statement creates the sequence `customers_seq` in the sample schema `oe`. This sequence could be used to provide customer ID numbers when rows are added to the `customers` table.

```
CREATE SEQUENCE customers_seq
 START WITH     1000
 INCREMENT BY   1
 NOCACHE
 NOCYCLE;
```

The first reference to `customers_seq.nextval` returns 1000. The second returns 1001. Each subsequent reference will return a value 1 greater than the previous reference.

CREATE SPFILE

Purpose

Use the `CREATE SPFILE` statement to create a server parameter file either from a traditional plain-text initialization parameter file or from the current system-wide settings. Server parameter files are binary files that exist only on the server and are called from client locations to start up the database.

Server parameter files let you make persistent changes to individual parameters. When you use a server parameter file, you can specify in an `ALTER SYSTEM SET` *`parameter`* statement that the new parameter value should be persistent. This means that the new value applies not only in the current instance, but also to any instances that are started up subsequently. Traditional plain-text parameter files do not let you make persistent changes to parameter values.

Server parameter files are located on the server, so they allow for automatic database tuning by Oracle Database and for backup by Recovery Manager (RMAN).

To use a server parameter file when starting up the database, you must create it using the `CREATE SPFILE` statement.

All instances in an Oracle Real Application Clusters environment must use the same server parameter file. However, when otherwise permitted, individual instances can have different settings of the same parameter within this one file. Instance-specific parameter definitions are specified as *`SID.parameter = value`*, where *`SID`* is the instance identifier.

The method of starting up the database with a server parameter file depends on whether you create a default or nondefault server parameter file. Refer to "Creating a Server Parameter File: Examples" for examples of how to use server parameter files.

Note on Creating Server Parameter Files in a CDB

When you create a server parameter file in a multitenant container database (CDB), the current container can be the root or a PDB.

- If the current container is the root, then the values that you set for initialization parameters in the root are used as default values for all other containers.
- If the current container is a PDB, then the database stores the PDB's initialization parameter values internally, rather than in a file. Therefore, you cannot specify an *`spfile_name`*. The values that you set for initialization parameters in the PDB are persistent and override any values set for those parameters in the root.

When PDB is in `MOUNT` state, any query on `V$parameter` (show parameter) shows the values from `ROOT` parameter table.

When PDB is in `OPEN` state, any query on `V$parameter` (show parameter) shows the values from PDB parameter table.

You can subsequently use the `ALTER SYSTEM` statement to modify initialization parameter values for the root or a PDB.

> **See Also:**
>
> - CREATE PFILE for information on creating a regular text parameter file from a binary server parameter file
> - *Oracle Database Administrator's Guide* for information on traditional plain-text initialization parameter files and server parameter files
> - *Oracle Real Application Clusters Administration and Deployment Guide* for information on using server parameter files in an Oracle Real Application Clusters environment

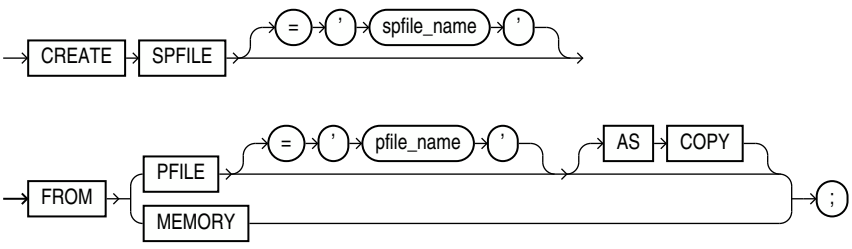
Prerequisites

You must have the `SYSBACKUP`, `SYSDBA`, `SYSDG`, or `SYSOPER` system privilege to execute this statement. You can execute this statement before or after instance startup. However, if you have already started an instance using *`spfile_name`*, you cannot specify the same *`spfile_name`* in this statement.

To create a server parameter file in a CDB, the current container must be the root and you must have the commonly granted `SYSBACKUP`, `SYSDBA`, `SYSDG`, or `SYSOPER` system privilege.

Syntax

***create_spfile*::=**



Semantics

spfile_name

This clause lets you specify a name for the server parameter file you are creating.

If you specify *`spfile_name`*, then Oracle Database creates a nondefault server parameter file.

- For *`spfile_name`*, you can specify a traditional filename, a file in an Oracle ACFS (Oracle Advanced Cluster File System) file system, or an Oracle Storage Management (Oracle ASM) filename.

- If you specify a traditional filename or a file in an Oracle ACFS file system, then *spfile_name* can include a path prefix. If you do not specify such a path prefix, then the database adds the path prefix for the default storage location, which is platform dependent.
- If you specify the Oracle ASM filename syntax, then the database creates the spfile in an Oracle ASM disk group.
- When using a nondefault server parameter file, you must specify the server parameter filename in the `STARTUP` command when you start up the database. The exception to this rule is as follows:
  - If the database is defined as a resource in Oracle Clusterware, the instance from which the command is issued is running, and you specify the *spfile_name*, specify the `FROM PFILE` clause, and omit the `AS COPY` clause, then this statement automatically updates the SPFILE in the database resource. In this case, you can start up the database without referring to the server parameter file by name. If the instance from which the command is issued is *not* running, then the SPFILE in the database resource must be updated manually using `srvctl modify database -d` *dbname* `-spfile` *spfile_path*.

If you omit *spfile_name*, then Oracle Database uses the platform-specific default server parameter filename. If such a file already exists on the server, then this statement overwrites it. When using a default server parameter file, you can start up the database without referring to the file by name.

Restriction on *spfile_name*

You cannot specify *spfile_name* when creating a server parameter file while connected to a PDB.

> **See Also:**
>
> - "Creating a Server Parameter File: Examples" for information on starting up the database with default and nondefault server parameter files
> - *file_specification* for the syntax of traditional and Oracle ASM filenames and ALTER DISKGROUP for information on modifying the characteristics of an Oracle ASM file
> - The appropriate operating-system-specific documentation for default parameter file names

pfile_name

Specify the traditional plain-text initialization parameter file from which you want to create a server parameter file. The traditional parameter file must reside on the server.

- If you specify *pfile_name* and the traditional parameter file does not reside in the default directory for parameter files on your operating system, then you must specify the full path.
- If you do not specify *pfile_name*, then Oracle Database looks in the default directory for parameter files on your operating system for the default parameter filename and uses that file. If that file does not exist in the expected directory, then the database returns an error.

> **Note:**
>
> In an Oracle Real Application Clusters environment, you must first combine all instance parameter files into one file before specifying that filename in this statement to create a server parameter file. For information on accomplishing this step, see *Oracle Real Application Clusters Administration and Deployment Guide*.

AS COPY

This clause applies only if the database is defined as a resource in Oracle Clusterware. By default, if you specify both the *spfile_name* and the `FROM PFILE` clause, then the `CREATE SPFILE` statement automatically updates the SPFILE in the database resource. You can specify `AS COPY` to prevent the database from updating the SPFILE in the database resource.

MEMORY

Specify `MEMORY` to create an spfile using the current system-wide parameter settings. In an Oracle RAC environment, the created file will contain the parameter settings from each instance.

Examples

Creating a Server Parameter File: Examples

The following example creates a default server parameter file from a traditional plain-text parameter file named `t_init1.ora`:

```
CREATE SPFILE
   FROM PFILE = '$ORACLE_HOME/work/t_init1.ora';
```

> **Note:**
>
> Typically you will need to specify the full path and filename for parameter files on your operating system.

When you create a default server parameter file, you subsequently start up the database using that server parameter file by using the SQL*Plus command `STARTUP` without the `PFILE` parameter, as follows:

```
STARTUP
```

The following example creates a nondefault server parameter file `s_params.ora` from a traditional plain-text parameter file named `t_init1.ora`:

```
CREATE SPFILE = 's_params.ora'
   FROM PFILE = '$ORACLE_HOME/work/t_init1.ora';
```

When you create a nondefault server parameter file, you subsequently start up the database by first creating a traditional parameter file containing the following single line:

```
spfile = 's_params.ora'
```

The name of this parameter file must comply with the naming conventions of your operating system. You then use the single-line parameter file in the `STARTUP` command. The following

example shows how to start up the database, assuming that the single-line parameter file is named `new_param.ora`:

```
STARTUP PFILE=new_param.ora
```

CREATE SYNONYM

Purpose

Use the `CREATE SYNONYM` statement to create a **synonym**, which is an alternative name for a table, view, sequence, operator, procedure, stored function, package, materialized view, Java class schema object, user-defined object type, or another synonym. A synonym places a dependency on its target object and becomes invalid if the target object is changed or dropped.

Synonyms provide both data independence and location transparency. Synonyms permit applications to function without modification regardless of which user owns the table or view and regardless of which database holds the table or view. However, synonyms are not a substitute for privileges on database objects. Appropriate privileges must be granted to a user before the user can use the synonym.

You can refer to synonyms in the following DML statements: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `FLASHBACK TABLE`, `EXPLAIN PLAN`, `LOCK TABLE`, `MERGE`, and `CALL` .

You can refer to synonyms in the following DDL statements: `AUDIT`, `NOAUDIT`, `GRANT`, `REVOKE`, and `COMMENT`.

> **See Also:**
>
> *Oracle Database Concepts* for general information on synonyms

Prerequisites

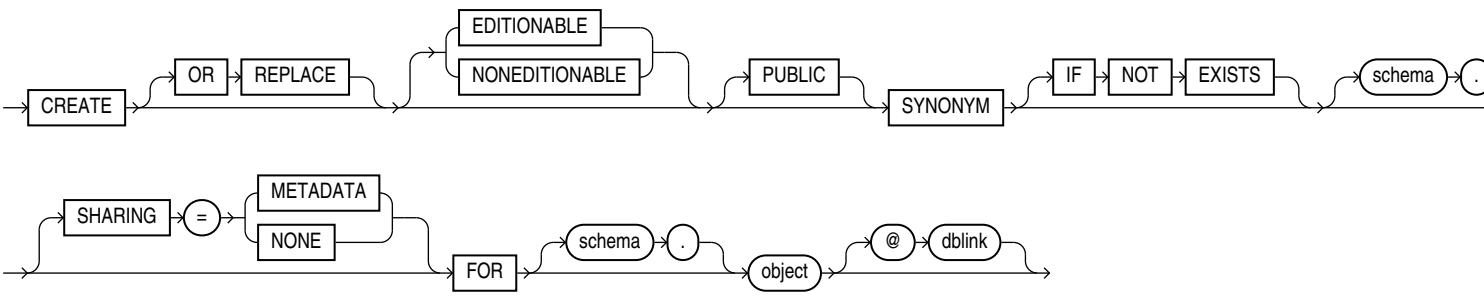
To create a private synonym in your own schema, you must have the `CREATE SYNONYM` system privilege.

To create a private synonym in another user's schema, you must have the `CREATE ANY SYNONYM` system privilege.

To create a `PUBLIC` synonym, you must have the `CREATE PUBLIC SYNONYM` system privilege.

Syntax

***create_synonym*::=**



Semantics

OR REPLACE

Specify `OR REPLACE` to re-create the synonym if it already exists. Use this clause to change the definition of an existing synonym without first dropping it.

Restriction on Replacing a Synonym

You cannot use the `OR REPLACE` clause for a type synonym that has any dependent tables or dependent valid user-defined object types.

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the synonym does not exist, a new synonym is created at the end of the statement.
- If the synonym exists, this is the synonym you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

[EDITIONABLE | NONEDITIONABLE]

Use these clauses to specify whether the synonym is an editioned or noneditioned object if editioning is enabled for the schema object type `SYNONYM` in *`schema`*. For private synonyms, the default is `EDITIONABLE`. For public synonyms, the default is `NONEDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

PUBLIC

Specify `PUBLIC` to create a public synonym. Public synonyms are accessible to all users. However each user must have appropriate privileges on the underlying object in order to use the synonym.

When resolving references to an object, Oracle Database uses a public synonym only if the object is not prefaced by a schema and is not followed by a database link.

If you omit this clause, then the synonym is private. A private synonym name must be unique in its schema. A private synonym is accessible to users other than the owner only if those users have appropriate privileges on the underlying database object and specify the schema along with the synonym name.

Notes on Public Synonyms

The following notes apply to public synonyms:

- If you create a public synonym and it subsequently has dependent tables or dependent valid user-defined object types, then you cannot create another database object of the same name as the synonym in the same schema as the dependent objects.
- Take care not to create a public synonym with the same name as an existing schema. If you do so, then all PL/SQL units that use that name will be invalidated.

schema

Specify the schema to contain the synonym. If you omit *schema*, then Oracle Database creates the synonym in your own schema. You cannot specify a schema for the synonym if you have specified PUBLIC.

synonym

Specify the name of the synonym to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

> **Note:**
>
> The maximum length of a synonym name is subject to the following rules:
>
> - If the COMPATIBLE initialization parameter is set to a value of 12.2 or higher, then the maximum length of a synonym name is 128 bytes. The database will allow you to create and drop synonyms of length 129 to 4000 bytes. However, unless these longer synonym names represent a Java name they will not work in any other SQL command.
> - If the COMPATIBLE initialization parameter is set to a value lower than 12.2, then the maximum length of a synonym name is 30 bytes. The database will allow you to create and drop synonyms of length 31 to 128 bytes. However, unless these longer synonym names represent a Java name they will not work in any other SQL command.
>
> The longer synonym names are transformed into obscure shorter strings for storage in the data dictionary.

> **See Also:**
>
> "CREATE SYNONYM: Examples" and "Oracle Database Resolution of Synonyms: Example"

SHARING

This clause applies only when creating a synonym in an application root. This type of synonym is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the synonym is shared, specify one of the following sharing attributes:

- METADATA - A metadata link shares the synonym's metadata, but its data is unique to each container. This type of synonym is referred to as a **metadata-linked application common object**.
- NONE - The synonym is not shared.

If you omit this clause, then the database uses the value of the DEFAULT_SHARING initialization parameter to determine the sharing attribute of the synonym. If the DEFAULT_SHARING initialization parameter does not have a value, then the default is METADATA.

You cannot change the sharing attribute of a synonym after it is created.

> **See Also:**
>
> - *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
> - *Oracle Database Administrator's Guide* for complete information on creating application common objects

FOR Clause

Specify the object for which the synonym is created. The schema object for which you are creating the synonym can be of the following types:

- Table or object table
- View or object view
- Sequence
- Stored procedure, function, or package
- Materialized view
- Java class schema object
- User-defined object type
- Synonym

The schema object need not currently exist and you need not have privileges to access the object.

Restriction on the FOR Clause

The schema object cannot be contained in a package.

schema

Specify the schema in which the object resides. If you do not qualify object with *`schema`*, then the database assumes that the schema object is in your own schema.

If you are creating a synonym for a procedure or function on a remote database, then you must specify *`schema`* in this `CREATE` statement. Alternatively, you can create a local public synonym on the database where the object resides. However, the database link must then be included in all subsequent calls to the procedure or function.

dblink

You can specify a complete or partial database link to create a synonym for a schema object on a remote database where the object is located. If you specify *`dblink`* and omit *`schema`*, then the synonym refers to an object in the schema specified by the database link. Oracle recommends that you specify the schema containing the object in the remote database.

If you omit *`dblink`*, then Oracle Database assumes the object is located on the local database.

Restriction on Database Links

You cannot specify *`dblink`* for a Java class synonym.

> **See Also:**
>
> - "References to Objects in Remote Databases " for more information on referring to database links
> - CREATE DATABASE LINK for more information on creating database links

Examples

CREATE SYNONYM: Examples

To define the synonym `offices` for the table `locations` in the schema `hr`, issue the following statement:

```
CREATE SYNONYM offices
   FOR hr.locations;
```

To create a `PUBLIC` synonym for the `employees` table in the schema `hr` on the `remote` database, you could issue the following statement:

```
CREATE PUBLIC SYNONYM emp_table
   FOR hr.employees@remote.us.example.com;
```

A synonym may have the same name as the underlying object, provided the underlying object is contained in another schema.

Oracle Database Resolution of Synonyms: Example

Oracle Database attempts to resolve references to objects at the schema level before resolving them at the `PUBLIC` synonym level. For example, the schemas `oe` and `sh` both contain tables named `customers`. In the next example, user `SYSTEM` creates a `PUBLIC` synonym named `customers` for `oe.customers`:

```
CREATE PUBLIC SYNONYM customers FOR oe.customers;
```

If the user `sh` then issues the following statement, then the database returns the count of rows from `sh.customers`:

```
SELECT COUNT(*) FROM customers;
```

To retrieve the count of rows from `oe.customers`, the user `sh` must preface `customers` with the schema name. (The user `sh` must have select permission on `oe.customers` as well.)

```
SELECT COUNT(*) FROM oe.customers;
```

If the user `hr`'s schema does not contain an object named `customers`, and if `hr` has select permission on `oe.customers`, then `hr` can access the `customers` table in `oe`'s schema by using the public synonym `customers`:

```
SELECT COUNT(*) FROM customers;
```

CREATE TABLE

Purpose

Use the `CREATE TABLE` statement to create one of the following types of tables:

- A **relational table** is the basic structure to hold user data.
- An **object table** that uses an object type for a column definition. An object table is explicitly defined to hold object instances of a particular type.
- A **JSON collection table** is a table that stores a collection of JSON documents (objects) in a JSON-type column while also guaranteeing a unique key per document.

You can also create an object type and then use it in a column when creating a relational table.

Tables are created with no data unless a subquery is specified. You can add rows to a table with the `INSERT` statement. After creating a table, you can define additional columns, partitions, and integrity constraints with the `ADD` clause of the `ALTER TABLE` statement. You can change the definition of an existing column or partition with the `MODIFY` clause of the `ALTER TABLE` statement.

See Also:

- *Oracle Database Administrator's Guide* and CREATE TYPE for more information about creating objects
- ALTER TABLE and DROP TABLE for information on modifying and dropping tables

Prerequisites

To create a **relational table** in your own schema, you must have the `CREATE TABLE` system privilege. To create a table in another user's schema, you must have the `CREATE ANY TABLE` system privilege. Also, the owner of the schema to contain the table must have either space quota on the tablespace to contain the table or the `UNLIMITED TABLESPACE` system privilege.

In addition to these table privileges, to create an object table or a relational table with an object type column, the owner of the table must have the `EXECUTE` object privilege in order to access all types referenced by the table, or you must have the `EXECUTE ANY TYPE` system privilege. These privileges must be granted explicitly and not acquired through a role.

Additionally, if the table owner intends to grant access to the table to other users, then the owner must have been granted the `EXECUTE` object privilege on the referenced types `WITH GRANT OPTION`, or have the `EXECUTE ANY TYPE` system privilege `WITH ADMIN OPTION`. Without these privileges, the table owner has insufficient privileges to grant access to the table to other users.

To enable a unique or primary key constraint, you must have the privileges necessary to create an index on the table. You need these privileges because Oracle Database creates an index on the columns of the unique or primary key in the schema containing the table.

To specify an edition in the *`evaluation_edition_clause`* or the *`unusable_editions_clause`*, you must have the `USE` privilege on the edition.

To specify the *`zonemap_clause`*, you must have the permissions necessary to create a zone map. Refer to the "Prerequisites" section in the documentation on `CREATE MATERIALIZED ZONEMAP`.

To create an **external table**, you must have the required read and write operating system privileges on the appropriate operating system directories. You must have the `READ` object privilege on the database directory object corresponding to the operating system directory in which the external data resides. You must also have the `WRITE` object privilege on the database

directory in which the files will reside if you specify a log file or bad file in the *opaque_format_spec* or if you unload data into an external table from a database table by specifying the AS *subquery* clause.

To create an **XMLType table** in a different database schema from your own, you must have not only privilege CREATE ANY TABLE but also privilege CREATE ANY INDEX. This is because a unique index is created on column OBJECT_ID when you create the table. Column OBJECT_ID stores a system-generated object identifier.

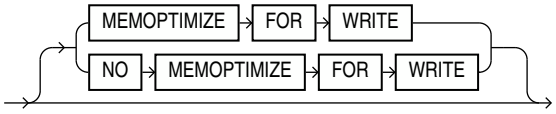
memoptimize_write_clause



Semantics

GLOBAL TEMPORARY

Specify `GLOBAL TEMPORARY` to create a temporary table, whose **definition** is visible to all sessions with appropriate privileges. The **data** in a temporary table is visible only to the session that inserts the data into the table.

When you first create a temporary table, its metadata is stored in the data dictionary, but no space is allocated for table data. Space is allocated for the table segment at the time of the first DML operation on the table. The temporary table definition persists in the same way as the definitions of regular tables, but the table segment and any data the table contains are either **session-specific** or **transaction-specific** data. You specify whether the table segment and data are session- or transaction-specific with the ON COMMIT clause.

You can perform DDL operations (such as `ALTER TABLE`, `DROP TABLE`, `CREATE INDEX`) on a temporary table only when no session is bound to it. A session becomes bound to a temporary table with an `INSERT` operation on the table. A session becomes unbound to a temporary table with a `TRUNCATE` statement or at session termination, or, for a transaction-specific temporary table, by issuing a `COMMIT` or `ROLLBACK` statement.

PRIVATE TEMPORARY

Specify `PRIVATE TEMPORARY` to create a private temporary table.

A private temporary table differs from a temporary table in that its **definition** and **data** are visible ***only*** within the session that created it.

Use the `ON COMMIT` clause to define the scope of a private temporary table: either **transaction** or **session**.

The `ON COMMIT` clause used with the keywords `DROP DEFINITION` creates a transaction-specific table whose data **and** definition are dropped when the transaction commits. This is the default behavior.

The `ON COMMIT` clause used with keywords `PRESERVE DEFINITION` creates a session-specific table whose definition is preserved when the transaction commits.

See here for usage details of the ON COMMIT clause.

Three DDL statements are supported for private temporary tables: `CREATE`, `DROP`, and `TRUNCATE`.

Restrictions on Temporary Tables

Temporary tables are subject to the following restrictions:

- Temporary tables cannot be partitioned, clustered, or index organized.

- You cannot specify any foreign key constraints on temporary tables.
- Temporary tables cannot contain columns of nested table.
- You cannot specify the following clauses of the *LOB_storage_clause*: TABLESPACE, *storage_clause*, or *logging_clause*.
- Parallel UPDATE, DELETE and MERGE are not supported for temporary tables.
- The only part of the *segment_attributes_clause* you can specify for a temporary table is TABLESPACE, which allows you to specify a single temporary tablespace.
- Distributed transactions are not supported for temporary tables.
- A temporary table cannot contain INVISIBLE columns.

Restrictions on Private Temporary Tables

In addition to the general limitations of temporary tables, private temporary tables are subject to the following restrictions:

You must be a user other than SYS to create private temporary tables.

You cannot specify the following constraints on private temporary tables that are permitted on global temporary tables:

- PRIMARY KEY constraint
- UNIQUE constraint
- CHECK constraint
- NOT NULL constraint
- The name of private temporary tables must *always* be prefixed with whatever is defined with the init.ora parameter PRIVATE_TEMP_TABLE_PREFIX. The default is ORA$PTT_.
- You cannot create indexes, materialized views, or zone maps on private temporary tables.
- You cannot define column with default values.
- You cannot reference private temporary tables in any permanent object, e.g. views or triggers.
- Private temporary tables are not visible through database links.
- You cannot associate table columns of private temporary tables with a domain using CREATE TABLE. Doing so results in the following error: Cannot associate a private temporary table with a domain.

> **See Also:**
>
> *Oracle Database Concepts* for information on temporary tables and "Creating a Table: Temporary Table Example"

SHARDED

Specify SHARDED to create a sharded table.

This clause is valid only if you are using Oracle Sharding, which is a data tier architecture in which data is horizontally partitioned across independent databases. Each database in such configuration is called a shard. All of the shards together make up a single logical database, which is referred to as a sharded database (SDB). Horizontal partitioning involves splitting a

table across shards so that each shard contains the table with the same columns but a different subset of rows. A table split up in this manner is called a sharded table.

When you create a sharded table, you must specify a tablespace set in which to create the table. There is no default tablespace set for sharded tables. See CREATE TABLESPACE SET for more information.

Oracle Sharding is based on the Oracle Partitioning feature. Therefore, a sharded table must be a partitioned or composite-partitioned table. When creating a sharded table, you must specify one of the *table_partitioning_clauses*. See *table_partitioning_clauses* for the full semantics of these clauses.

Restrictions on Sharded Tables

The following restrictions apply to sharded tables:

- In system-managed sharding you can create multiple root tables (and therefore table families) without throwing `ORA-02530` , when the `CREATE SHARDED TABLE` statement does not contain a `PARTITION BY REFERENCE` or `PARENT` clause and there is already a root table in existence.
- A sharded table cannot be a temporary table or an index-organized table.
- A sharded table cannot contain a nested table column or an identity column.
- You cannot specify a tablespace for a sharded system or a composite sharded table with the `TABLESPACE`clause, because system or composite sharded tables require tablespace sets.
- You cannot create tablespace sets in a user-defined sharding environment.
- A sharded tablespace is required for sharded tables. Normal tablespaces are not supported.
- You cannot specify the same tablespace for multiple partitions of the sharded table. This rule applies to subpartitions also. The same tablespace cannot be specified for subpartitions belonging to different partitions of a sharded table.
- You must specify a tablespace per partition of non-reference partitioned sharded tables.
- For user defined sharding the partition method must be range or list. Autolist and Interval partitioning is not supported.
- The list partition method can only have one partitioning column.
- Default partitions are not supported in list partitioned tables.
- NULL partitions are not supported in list partitioned tables.
- A primary key constraint defined on a sharded table must contain the sharding columns. A foreign key constraint on a column of a sharded table referencing a duplicated table column is not supported.
- System partitioning and interval-range partitioning are not supported for sharded tables.
- You cannot specify a virtual (expression) column in a sharded table in the `PARTITION BY` or `PARTITIONSET BY` clauses.
- `XMLType` columns for sharded tables are defaulted to `TRANSPORTABLE BINARY XML`, which is the only storage type allowed. Any other storage clause for `XMLType` will throw an error.

> **See Also:**
>
> - *Using Oracle Sharding*
> - *Oracle Database Administrator's Guide*

DUPLICATED

This clause is valid only if you are using Oracle Sharding. Specify `DUPLICATED` to create a duplicated table, which is duplicated on all shards. It can be a nonpartitioned table or partitioned table.

Duplicated tables are not tied to any table family.

Restrictions on Duplicated Tables

The following restrictions apply to duplicated tables:

- A duplicated table cannot contain a `LONG` column.
- The maximum number of non-primary key columns in a duplicated table is 999.
- `XMLType` columns for duplicated tables are defaulted to `TRANSPORTABLE BINARY XML`, which is the only storage type allowed. Any other storage clause for `XMLType` will throw an error.
- A duplicated table cannot be a temporary table.
- A duplicated table cannot be a reference-partitioned table or a system-partitioned table.
- You cannot specify `NOLOGGING` or `PARALLEL` for a duplicated table.
- You cannot enable a duplicated table for the In-Memory Column Store.

IMMUTABLE

Specify the `IMMUTABLE` keyword to create an append-only table that protects data from unauthorized modification by insiders.

You can create a blockchain table that emphasizes its immutability by using the keywords `IMMUTABLE BLOCKCHAIN` in `CREATE TABLE`.

You must specify the mandatory *`immutable_table_clauses`* when you create an immutable table using the `CREATE IMMUTABLE TABLE` statement.

Prerequistes

- The `COMPATIBLE` initialization parameter must be set to 19.11.0.0 or higher.
- The `CREATE TABLE` system privilege is required to create immutable tables in your own schema. The `CREATE ANY TABLE` system privilege is required to create immutable tables in another user's schema.
- The `NO DROP` and `NO DELETE` clauses are mandatory.

BLOCKCHAIN

Specify the `BLOCKCHAIN` keyword to create a blockchain table.

You must specify the mandatory *`blockchain_table_clauses`* when you create a blockchain table using the `CREATE BLOCKCHAIN TABLE` statement.

When you create a blockchain table, an entry is created in the dictionary table `blockchain_table$` owned by `SYS` .

Restrictions

The following `CREATE TABLE` clauses are disallowed with the creation of blockchain tables:

- `ORGANIZATION INDEX`
- `ORGANIZATION EXTERNAL`
- `NESTED TABLE`

> **See Also:**
>
> - *Managing Immutable Tables*
> - *Managing Blockchain Tables*

IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the table does not exist, a new table is created at the end of the statement.
- If the table exists, this is the table you have at the end of the statement. A new one is not created because the older table is detected.

Using `IF EXISTS` with `CREATE TABLE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement`.

schema

Specify the schema to contain the table. If you omit *`schema`*, then the database creates the table in your own schema.

table

Specify the name of the table or object table to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more on sharded tables.

SHARING

This clause applies only when creating a table in an application root. This type of table is called an application common object and its data can be shared with the application PDBs that belong to the application root. To determine how the table data is shared, specify one of the following sharing attributes:

- `METADATA` - A metadata link shares the table's metadata, but its data is unique to each container. This type of table is referred to as a **metadata-linked application common object**.
- `DATA` - A data link shares the table, and its data is the same for all containers in the application container. Its data is stored only in the application root. This type of table is referred to as a **data-linked application common object**.
- `EXTENDED DATA` - An extended data link shares the table, and its data in the application root is the same for all containers in the application container. However, each application PDB in the application container can store data that is unique to the application PDB. For this type of table, data is stored in the application root and, optionally, in each application PDB. This type of table is referred to as an **extended data-linked application common object**.
- `NONE` - The table is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the table. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

When creating a relational table, you can specify `METADATA`, `DATA`, `EXTENDED DATA`, or `NONE`.

When creating an object table or an `XMLTYPE` table, you can specify only `METADATA` or `NONE`.

You cannot change the sharing attribute of a table after it is created.

> **See Also:**
>
> - *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
> - *Oracle Database Administrator's Guide* for complete information on creating application common objects

relational_table

This clause lets you create a relational table.

relational_properties

The relational properties describe the components of a relational table.

column_definition

The *column_definition* lets you define the characteristics of the column.

Specifying *column_definition* with AS *subquery*

If you specify the `AS` *subquery* clause, and each column returned by *subquery* has a column name or is an expression with a specified column alias, then you can omit the *column_definition* clause. In this case, the names of the columns of table are the same as the names of the columns returned by *subquery*. The exception is creating an index-organized table, for which you must specify the *column_definition* clause, because you must designate a primary key column. Regardless of the table type, if you specify the *column_definition* clause and the `AS` *subquery* clause, then you must omit *datatype* from the *column_definition* clause.

column

Specify the name of a column of the table. The name must satisfy the requirements listed in "Database Object Naming Rules ".

If you also specify `AS subquery`, then you can omit `column` and `datatype` unless you are creating an index-organized table. If you specify `AS subquery` when creating an index-organized table, then you must specify `column`, and you must omit `datatype`.

The absolute maximum number of columns in a table is 1000, if the `MAX_COLUMNS` initialization parameter = `STANDARD`, or 4096 columns if `MAX_COLUMNS` = `EXTENDED`. See *Oracle Database Reference* for more on the `MAX_COLUMNS` initialization parameter.

When you create an object table or a relational table with columns of object, nested table, varray, or REF type, Oracle Database maps the columns of the user-defined types to relational columns, in effect creating hidden columns that count toward the 1000-column limit. A relational column that stores a user-defined type attribute inherits the collation property of the attribute. In Oracle Database 12*c* Release 2 (12.2), user-defined types are created using the pseudo-collation property `USING_NLS_COMP` and their corresponding relational columns inherit this property.

datatype_domain

datatype

Specify the data type of a column in `datatype`.

In general, you must specify `datatype`. However, the following exceptions apply:

- You must omit `datatype` if you specify the `AS subquery` clause.
- You can also omit `datatype` if the statement designates the column as part of a foreign key in a referential integrity constraint. Oracle Database automatically assigns to the column the data type of the corresponding column of the referenced key of the referential integrity constraint.

Restrictions on Table Column Data Types

- Do not create a table with `LONG` columns. Use LOB columns (`CLOB`, `NCLOB`, `BLOB`) instead. `LONG` columns are supported only for backward compatibility.
- You can specify a column of type `ROWID`, but Oracle Database does not guarantee that the values in such columns are valid rowids.

> **See Also:**
>
> "Data Types " for information on `LONG` columns and on Oracle-supplied data types

You can specify a user-defined data type as non-persistable when creating or altering the data type. Instances of non-persistable types cannot persist on disk. See CREATE TYPE for more on user-defined data types declared as non-persistable types.

domain_clause

Use this clause to associate columns with a domain. You can associate non-strict domains with a table column with a compatibile type with any limit. For example, a number(10) domain can be assigned to columns with number(9) or number(11). For strict domains you can only associate their columns with table columns with a compatible type and identical type limits. For

example, a number(10) domain column can only be assigned to numeric columns with precision 10, like decimal(10) or numeric(10).

The position of columns in this clause is the same as those in the domain. The number of columns listed must be the same as in *domain_name*.

Each column can belong to at most one domain. If a column is in two or more domains, the statement will error.

If you specify the data type, you must use the DOMAIN keyword. You can omit the DOMAIN keyword, if you omit the data type and just use the domain owner or domain name.

USING

The USING clause defines the discriminant columns in flexible domains. This clause is mandatory when associating columns with a flexible domain.

The columns in the DOMAIN and USING clauses must be different.

RESERVABLE

Reservable columns provide for lock-free reservations. Lock-free reservations allow other concurrent transactions updating the reservable columns to proceed without being blocked. Lock-free reservations hold locks on hot data for short intervals of time and only when the value is modified during the commit of the transaction.

Specify RESERVABLE on a column to make it reservable on columns with numeric data type.

Guidelines and Restrictions for Reservable Columns

- The schema definition of user tables declares the reservable columns with the RESERVABLE keyword.
- A reservable column can be specified only on columns of the following numeric data types: NUMBER, INTEGER, and FLOAT.
- A reservable column cannot be a Primary Key or an identity column (or virtual (expression) column) because the reservable column is an aggregate type.
- A user table can have at most ten reservable columns.
- User tables that have reservable columns must have a Primary Key.
- Indexes are not supported on reservable columns.
- Composite reservable columns are not allowed. Reservable columns can be included only in CHECK constraints expression.
- The CHECK constraint can be at the column-level or table-level. User-defined operational constraints are used for reservable columns to ensure application correctness.
- Partitioning cannot be made on reservable columns. Transactions with pending reservations must finalize before you can drop the reservable column or mark the column as UNUSED.

See Also:

- *Using Lock-Free Reservation* of the *Database Development Guide*.
- Columns section in *Tables and Table Clusters* of *Database Concepts*.

COLLATE

The COLLATE clause lets you specify a data-bound collation for the column.

For *column_collation_name*, specify a valid named collation or pseudo-collation. For columns of data type CLOB or NCLOB, the only allowed value for *column_collation_name* is the pseudo-collation USING_NLS_COMP.

If you omit this clause, then the column is assigned:

- the pseudo-collation USING_NLS_COMP, if the column has the data type CLOB or NCLOB, or
- the collation of the corresponding parent key column, if the column belongs to a foreign key, or
- the default collation for the table as it stands at the time the column is created.

Refer to the DEFAULT COLLATION clause for more information on the default collation for a table.

You can specify the COLLATE clause only if the COMPATIBLE initialization parameter is set to 12.2 or greater, and the MAX_STRING_SIZE initialization parameter is set to EXTENDED.

SORT

The SORT keyword is valid only if you are creating this table as part of a hash cluster and only for columns that are also cluster columns.

Table rows are hashed into buckets on cluster key columns without SORT, and then sorted in each bucket on the columns with this clause. This may improve response time during subsequent operations on the clustered data.

> **See Also:**
>
> - "CLUSTER Clause" for information on creating a cluster table
> - *Managing Hash Clusters*

VISIBLE | INVISIBLE

Use this clause to specify whether *column* is VISIBLE or INVISIBLE. The default is VISIBLE.

INVISIBLE columns are user-specified hidden columns. To display or assign a value to an INVISIBLE column, you must specify its name explicitly. For example:

- The SELECT * syntax will not display an INVISIBLE column. However, if you include an INVISIBLE column in the select list of a SELECT statement, then the column will be displayed.
- You cannot implicitly specify a value for an INVISIBLE column in the VALUES clause of an INSERT statement. You must specify the INVISIBLE column in the column list.
- You must explicitly specify an INVISIBLE column in Oracle Call Interface (OCI) describes.
- You can configure SQL*Plus to allow INVISIBLE column information to be viewed with the DESCRIBE command. Refer to *SQL*Plus User's Guide and Reference* for more information.

Notes on VISIBLE and INVISIBLE Columns

The following notes apply to VISIBLE and INVISIBLE columns:

- An INVISIBLE column can be used as a partitioning key when specified as part of CREATE TABLE.
- You can specify INVISIBLE columns in a *column_expression*.
- A virtual (expression) column can be an INVISIBLE column.
- PL/SQL %ROWTYPE attributes do not show INVISIBLE columns.
- The COLUMN_ID column of the ALL_, DBA_, and USER_TAB_COLUMNS data dictionary views determines the order in which a SELECT * query returns columns for a table, view, or materialized view. The value of COLUMN_ID is NULL for INVISIBLE columns. When you make an invisible column visible, it will be assigned the next highest available COLUMN_ID value. When you make a visible column invisible, its COLUMN_ID value is set to NULL and COLUMN_ID is decremented by 1 for any columns with a higher COLUMN_ID.

Restrictions on VISIBLE and INVISIBLE Columns

The following restrictions apply to VISIBLE and INVISIBLE columns:

- INVISIBLE columns are not supported in external tables, cluster tables, or temporary tables.
- You cannot make a system-generated hidden column visible.

> **Note:**
>
> To determine whether a column is a system-generated hidden column, query the HIDDEN_COLUMN and USER_GENERATED columns of the ALL_, DBA_, and USER_TAB_COLS data dictionary views. Refer to *Oracle Database Reference* for more information.

DEFAULT

The DEFAULT clause lets you specify a value to be assigned to the column if a subsequent INSERT statement omits a value for the column. The data type of the expression must match the data type specified for the column. The column must also be large enough to hold this expression.

The DEFAULT expression can include any SQL function as long as the function does not return a literal argument, a column reference, or a nested function invocation.

The DEFAULT expression can include the sequence pseudocolumns CURRVAL and NEXTVAL, as long as the sequence exists and you have the privileges necessary to access it. Users who perform subsequent inserts that use the DEFAULT expression must have the INSERT privilege on the table and the SELECT privilege on the sequence. If the sequence is later dropped, then subsequent INSERT statements where the DEFAULT expression is used will result in an error. If you do not fully qualify the sequence by specifying the sequence owner, for example, SCOTT.SEQ1, then Oracle Database will default the sequence owner to be the user who issues the CREATE TABLE statement. For example, if user MARY creates SCOTT.TABLE and refers to a sequence that is not fully qualified, such as SEQ2, then the column will use sequence MARY.SEQ2. Synonyms on sequences undergo a full name resolution and are stored as the fully qualified sequence in the data dictionary; this is true for public and private synonyms. For example, if user BETH adds a column referring to public or private synonym SYN1 and the synonym refers to PETER.SEQ7, then the column will store PETER.SEQ7 as the default.

Restrictions on Default Column Values

Default column values are subject to the following restrictions:

- A `DEFAULT` expression cannot contain references to PL/SQL functions or to other columns, the pseudocolumns `LEVEL`, `PRIOR`, and `ROWNUM`, or date constants that are not fully specified.
- The expression can be of any form except a scalar subquery expression.

> **See Also:**
>
> "About SQL Expressions " for the syntax of *expr*

ON NULL

If you specify the `ON NULL` clause, then Oracle Database assigns the `DEFAULT` column value when a subsequent `INSERT` statement attempts to assign a value that evaluates to NULL.

When you specify `ON NULL`, the `NOT NULL` constraint and `NOT DEFERRABLE` constraint state are implicitly specified. If you specify an inline constraint that conflicts with `NOT NULL` and `NOT DEFERRABLE`, then an error is raised.

If you specify `DEFAULT ON NULL FOR INSERT AND UPDATE`, the `DEFAULT ON NULL` semantics applies for `INSERT`, including the insert branch of merge and multi-table insert and `UPDATE`, including the update branch of merge.

If you specify `DEFAULT ON NULL FOR INSERT ONLY`, it is equivalent to `DEFAULT ON NULL`. It means that `DEFAULT ON NULL` semantics will apply for `INSERT` including the insert branch of merge and multi-table insert only.

In before-row DML triggers, *:new.column-name* shows the defaulted value, and you can override the default value in the trigger. If a column is defined as `DEFAULT ON NULL FOR INSERT AND UPDATE` and the trigger updates the value to `NULL`, then `DEFAULT ON NULL` semantics will not apply – i.e. `NULL` will not be converted to the column default value.

In the following trigger, column `c2` has `DEFAULT ON NULL` semantics. When the trigger is executed, an error is raised since it sets `c2` to `NULL`:

```
create or replace trigger t1_t
before insert or update on t1 for each row
begin
  :new.c2 := NULL;
end;
```

Restriction on the ON NULL Clause

You cannot specify this clause for an object type column or a `REF` column.

> **See Also:**
>
> "Creating a Table with a DEFAULT ON NULL Column Value: Example"

annotations_clause

The *annotation_name* is an identifier that can have up to 4000 characters. If the annotation name is a reserved word it must be provided in double quotes. When a double quoted identifier is used, the identifier can also contain whitespace characters. However, identifiers that contain only whitespace characters are not accepted.

For examples see Add Annotations at Table Creation: Example

For the full semantics of the annotations clause see *annotations_clause*.

identity_clause

Use this clause to specify an identity column. The identity column will be assigned an increasing or decreasing integer value from a sequence generator for each subsequent INSERT statement. You can use the *identity_options* clause to configure the sequence generator.

To create an identity column in a schema other than your own, you must have the CREATE ANY TABLE, CREATE ANY SEQUENCE, and SELECT ANY SEQUENCE system privileges.

ALWAYS

If you specify ALWAYS, then Oracle Database always uses the sequence generator to assign a value to the column. If you attempt to explicitly assign a value to the column using INSERT or UPDATE, then an error will be returned. This is the default.

BY DEFAULT

If you specify BY DEFAULT, then Oracle Database uses the sequence generator to assign a value to the column by default, but you can also explicitly assign a specified value to the column. If you specify ON NULL, then Oracle Database uses the sequence generator to assign a value to the column when a subsequent INSERT statement attempts to assign a value that evaluates to NULL. See *column_definition* ON NULL for full semantics.

identity_options

Use the *identity_options* clause to configure the sequence generator. The *identity_options* clause has the same parameters as the CREATE SEQUENCE statement. Refer to CREATE SEQUENCE for a full description of these parameters and characteristics. The exception is START WITH LIMIT VALUE, which is specific to *identity_options* and can only be used with ALTER TABLE MODIFY. Refer to identity_options for more information.

> **Note:**
>
> When you create an identity column, Oracle recommends that you specify the CACHE clause with a value higher than the default of 20 to enhance performance.

Restrictions on Identity Columns

Identity columns are subject to the following restrictions:

- You can specify only one identity column per table.
- If you specify *identity_clause*, then you must specify a numeric data type for *datatype* in the *column_definition* clause. You cannot specify a user-defined data type.

- If you specify *identity_clause*, then you cannot specify the DEFAULT clause in the *column_definition* clause.
- When you specify *identity_clause*, the NOT NULL constraint and NOT DEFERRABLE constraint state are implicitly specified. If you specify an inline constraint that conflicts with NOT NULL and NOT DEFERRABLE, then an error is raised.
- If an identity column is encrypted, then the encryption algorithm may be inferred. Oracle recommends that you use a strong encryption algorithm on identity columns.
- CREATE TABLE AS SELECT will not inherit the identity property on a column.

> **See Also:**
>
> "Creating a Table with an Identity Column: Examples"

encryption_spec

Starting with Oracle Database 23ai, the Transparent Data Encryption (TDE) decryption libraries for the GOST and SEED algorithms are deprecated, and encryption to GOST and SEED are desupported.

GOST 28147-89 has been deprecated by the Russian government, and SEED has been deprecated by the South Korean government. If you need South Korean government-approved TDE cryptography, then use ARIA instead. If you are using GOST 28147-89, then you must decrypt and encrypt with another supported TDE algorithm. The decryption algorithms for GOST 28147-89 and SEED are included in Oracle Database 23ai, but are deprecated, and the GOST encryption algorithm is desupported with Oracle Database 23ai. If you are using GOST or SEED for TDE encryption, then Oracle recommends that you decrypt and encrypt with another algorithm before upgrading to Oracle Database 23ai. However, with the exception of the HP Itanium platform, the GOST and SEED decryption libraries are available with Oracle Database 23ai, so you can also decrypt after upgrading.

The ENCRYPT clause lets you use the Transparent Data Encryption (TDE) feature to encrypt the column you are defining. You can encrypt columns of type CHAR, NCHAR, VARCHAR2, NVARCHAR2, NUMBER, DATE, LOB, and RAW. The data does not appear in its encrypted form to authorized users, such as the user who encrypts the column.

> **Note:**
>
> Column encryption requires that a system administrator with appropriate privileges has initialized the security module, opened a keystore, and set an encryption key. Refer to *Transparent Data Encryption* for general information about column encryption and to *security_clauses* for related ALTER SYSTEM statements.

USING '*encrypt_algorithm*'

Use this clause to specify the name of the algorithm to be used. Valid algorithms are AES256, AES192, AES128 and 3DES168. If the COMPATIBLE initialization parameter is set to 12.2 or higher, then the following algorithms are also valid: ARIA128, ARIA192, ARIA256, GOST256, and SEED128. If you omit this clause, then the database uses AES192. If you encrypt more than one column in the same table, and if you specify the USING clause for one of the columns, then you must specify the same encryption algorithm for all the encrypted columns.

IDENTIFIED BY *password*

If you specify this clause, then the database derives the column key from the specified password.

'***integrity_algorithm***'

Use this clause to specify the integrity algorithm to be used. Valid integrity algorithms are `SHA-1` and `NOMAC`.

- If you specify `SHA-1`, then TDE uses the Secure Hash Algorithm (SHA-1) and adds a 20-byte Message Authentication Code (MAC) to each encrypted value for integrity checking. This is the default.
- If you specify `NOMAC`, then TDE does not add a MAC and does not perform the integrity check. This saves 20 bytes of disk space per encrypted value. Refer to *Transparent Data Encryption* for more information on using `NOMAC` to save disk space and improve performance.

All encrypted columns in a table must use the same integrity algorithm. If you already have a table column using the `SHA-1` algorithm, then you cannot use the `NOMAC` parameter to encrypt another column in the same table. Refer to the REKEY *encryption_spec* clause of `ALTER TABLE` to learn how to change the integrity algorithm used by all encrypted columns in a table.

SALT | NO SALT

Specify `SALT` to instruct the database to append a random string, called "salt," to the clear text of the column before encrypting it. This is the default.

Specify `NO SALT` to prevent the database from appending salt to the clear text of the column before encrypting it.

The following considerations apply when specifying `SALT` or `NO SALT` for encrypted columns:

- If you want to use the column as an index key, then you must specify `NO SALT`. Refer to *Transparent Data Encryption* for a description of "salt" in this context.
- If you specify table compression for the table, then the database does not compress the data in encrypted columns with `SALT`.

You cannot specify `SALT` or `NO SALT` for LOB encryption.

Restrictions on *encryption_spec*

The following restrictions apply to column encryption:

- Transparent Data Encryption is not supported by the traditional import and export utilities or by transportable-tablespace-based export. Use the Data Pump import and export utilities with encrypted columns instead.
- To encrypt a column in an external table, the table must use `ORACLE_DATAPUMP` as its access type.
- You cannot encrypt a column in tables owned by `SYS`.
- You cannot encrypt a foreign key column.

> **See Also:**
>
> *Transparent Data Encryption* for more information about Transparent Data Encryption

virtual_column_definition

Use *virtual_column_definition* to create a virtual column, also known as an expression column. Expression columns can be virtual, meaning not stored on disk, or materialized, meaning stored on disk. Depending on whether such a column is virtual or materialized, the database derives the values on demand at access time (virtual) or by computing the values and storing them on disk at DML time (materialized). Such columns can be used in queries, DML, and DDL statements. They can be indexed, and you can collect statistics on them. Thus, they can be treated just like other columns. Exceptions and restrictions are listed below in "Notes on Virtual (Expression) Columns" and "Restrictions on Virtual (Expression) Columns".

column

For *column*, specify the name of the virtual (expression) column.

datatype

You can optionally specify the data type of the virtual (expression) column. If you omit *datatype*, then the database determines the data type of the column based on the data type of the underlying expressions. All Oracle scalar data types and XMLType are supported.

COLLATE

The COLLATE clause lets you specify a data-bound collation for the virtual (expression) column. For *column_collation_name*, specify a valid named collation or pseudo-collation. If you omit this clause, then the column is assigned the default collation for the table as it stands at the time the column is created, unless the column belongs to a foreign key, in which case it inherits the collation from the corresponding column of the parent key. Refer to the DEFAULT COLLATION clause for more information on the default collation for a table.

You can specify the COLLATE clause only if the COMPATIBLE initialization parameter is set to 12.2 or greater, and the MAX_STRING_SIZE initialization parameter is set to EXTENDED.

VISIBLE | INVISIBLE

Use this clause to specify whether the virtual (expression) column is VISIBLE or INVISIBLE. The default is VISIBLE. For complete information, refer to "VISIBLE | INVISIBLE".

GENERATED ALWAYS

The optional keywords GENERATED ALWAYS are provided for semantic clarity.

column_expression

The AS *column_expression* clause determines the content of the column. Refer to "Column Expressions " for more information on *column_expression*.

VIRTUAL

Use VIRTUAL to create an expression column that is virtual.

MATERIALIZED

Use MATERIALIZED to store the computed value of an expression column on disk. Rather than computing the values at access time, the computation will take place at DML time.

An alternate way to specify a materialized expression column is to use the keyword STORED instead of MATERIALIZED.

evaluation_edition_clause

You must specify this clause if *column_expression* refers to an editioned PL/SQL function. Use this clause to specify the edition that is searched during name resolution of the editioned PL/SQL function—the evaluation edition.

- Specify `CURRENT EDITION` to search the edition in which this DDL statement is executed.
- Specify `EDITION` *edition* to search *edition*.
- Specifying `NULL EDITION` is equivalent to omitting the *evaluation_edition_clause*.

If you omit the *evaluation_edition_clause*, then editioned objects are invisible during name resolution and an error will result. If the evaluation edition is dropped, then a subsequent query on the virtual (expression) column will result in an error.

The database does not maintain dependencies on the functions referenced by a virtual (expression) column. Therefore, if a virtual (expression) column refers to a noneditioned function, and the function becomes editioned, then the following operations may raise an error:

- Querying the virtual (expression) column
- Updating a row that includes the virtual (expression) column
- Firing a trigger that accesses the virtual (expression) column

> **See Also:**
>
> *Oracle Database Development Guide* for more information on specifying the evaluation edition for a virtual (expression) column

unusable_editions_clause

This clause lets you specify that the virtual (expression) column expression is unusable for evaluating queries in one or more editions. The remaining editions form a range of editions in which it is safe for the optimizer to use the virtual (expression) column expression to evaluate queries.

For example, suppose you define a function-based index on the virtual (expression) column. The optimizer can use the function-based index to evaluate queries that contain the virtual (expression) column expression in their `WHERE` clause. If a query is compiled in an edition that is in the usable range of editions for the virtual (expression) column, then the optimizer will consider using the index to evaluate the query. If a query is compiled in an edition outside the usable range of editions for the virtual (expression) column, then the optimizer will not consider using the index.

> **See Also:**
>
> *Oracle Database Concepts* for more information on optimization with function-based indexes

UNUSABLE BEFORE Clause

This clause lets you specify that the virtual (expression) column expression is unusable for evaluating queries in the ancestors of an edition.

- If you specify `CURRENT EDITION`, then the virtual (expression) column expression is unusable in the ancestors of the edition in which this DDL statement is executed.
- If you specify `EDITION` *`edition`*, then the virtual (expression) column expression is unusable in the ancestors of the specified *`edition`*.

UNUSABLE BEGINNING WITH Clause

This clause lets you specify that the virtual (expression) column expression is unusable for evaluating queries in an edition and its descendants.

- If you specify `CURRENT EDITION`, then the virtual (expression) column expression is unusable in the edition in which this DDL statement is executed and its descendants.
- If you specify `EDITION` *`edition`*, then the virtual (expression) column expression is unusable in the specified *`edition`* and its descendants.
- Specifying `NULL EDITION` is equivalent to omitting the `UNUSABLE BEGINNING WITH` clause.

If an edition specified in this clause is subsequently dropped, there is no effect on the virtual (expression) column.

Notes on Virtual (Expression) Columns

- If *`column_expression`* refers to a column on which column-level security is implemented, then the virtual (expression) column does not inherit the security rules of the base column. In such a case, you must ensure that data in the virtual (expression) column is protected, either by duplicating a column-level security policy on the virtual (expression) column or by applying a function that implicitly masks the data. For example, it is common for credit card numbers to be protected by a column-level security policy, while still allowing call center employees to view the last four digits of the credit card number for validation purposes. In such a case, you could define the virtual (expression) column to take a substring of the last four digits of the credit card number.
- A table index defined on a virtual (expression) column is equivalent to a function-based index on the table.
- You cannot directly update a virtual (expression) column. Thus, you cannot specify a virtual (expression) column in the `SET` clause of an `UPDATE` statement. However, you can specify a virtual (expression) column in the `WHERE` clause of an `UPDATE` statement. Likewise, you can specify a virtual (expression) column in the `WHERE` clause of a `DELETE` statement to delete rows from a table based on the derived value of the virtual (expression) column.
- A query that specifies in its `FROM` clause a table containing a virtual (expression) column is eligible for result caching. Refer to "RESULT_CACHE Hint " for more information on result caching.
- The *`column_expression`* can refer to a PL/SQL function if the function is explicitly designated `DETERMINISTIC` during its creation. However, if the function is subsequently replaced, definitions dependent on the virtual (expression) column are not invalidated. In such a case, if the table contains data, queries that reference the virtual (expression) column may return incorrect results if the virtual (expression) column is used in the definition of constraints, indexes, or materialized views or for result caching. Therefore, in order to replace the deterministic PL/SQL function for a virtual (expression) column.
  - Disable and re-enable any constraints on the virtual (expression) column.
  - Rebuild any indexes on the virtual (expression)column.
  - Fully refresh materialized views accessing the virtual (expression) column.
  - Flush the result cache if cached queries have accessed the virtual (expression) column.

  - Regather statistics on the table.
- A virtual (expression) column can be an `INVISIBLE` column. The *`column_expression`* can contain `INVISIBLE` columns.

Restrictions on Virtual (Expression) Columns

- You can create virtual (expression) columns only in relational heap tables. virtual (expression) columns are not supported for index-organized, external, object, cluster, or temporary tables.
- The *`column_expression`* in the `AS` clause has the following restrictions:
  - It cannot refer to another virtual (expression) column by name.
  - Any columns referenced in *`column_expression`* must be defined on the same table.
  - It can refer to a deterministic user-defined function, but if it does, then you cannot use the virtual (expression) column as a partitioning key column.
  - The output of *`column_expression`* must be a scalar value.

> **See Also:**
>
> "Column Expressions " for additional information and restrictions on *`column_expression`*

- The virtual (expression) column cannot be an Oracle supplied data type, a user-defined type, or LOB or `LONG RAW`.
- You cannot specify a call to a PL/SQL function in the defining expression for a virtual (expression) column that you want to use as a partitioning column.

> **See Also:**
>
> "Adding a Virtual Table Column: Example" and *Oracle Database Administrator's Guide* for examples of creating tables with virtual (expression) columns

period_definition

Use the *`period_definition`* clause to create a valid time dimension for *`table`*.

This clause implements Temporal Validity support for *`table`*. If you specify this clause, then one column in *`table`*, the start time column, contains a start date or timestamp, and another column in *`table`*, the end time column, contains an end date or timestamp. These two columns define a valid time dimension for *`table`*—that is, a period of time for which each row is considered valid. You can use Oracle Flashback Query to retrieve rows from *`table`* based on whether they are considered valid as of a specified time, before a specified time, or during a specified time period.

You can specify at most one valid time dimension when you create a table. You can subsequently add additional valid time dimensions to a table with the *add_period_clause* of `ALTER TABLE`.

valid_time_column

Specify the name of the valid time dimension. The name must satisfy the requirements listed in "Database Object Naming Rules ". Oracle Database creates an INVISIBLE virtual (expression) column with this name of data type NUMBER in *table*.

start_time_column* and *end_time_column

You can optionally specify these clauses as follows:

- Use *start_time_column* to specify the name of the start time column, which contains the start date or timestamp.
- Use *end_time_column* to specify the name of the end time column, which contains the end date or timestamp.

The names you specify for *start_time_column* and *end_time_column* must satisfy the requirements listed in "Database Object Naming Rules ".

If you specify these clauses, then you must define *start_time_column* and *end_time_column* in the *column_definition* clause of CREATE TABLE. Each column must be of a datetime data type (DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, or TIMESTAMP WITH LOCAL TIME ZONE) and can be VISIBLE or INVISIBLE.

If you do not specify these clauses, then Oracle Database creates a start time column named *valid_time_column*_START, and an end time column named *valid_time_column*_END. These columns are of data type TIMESTAMP WITH TIME ZONE and are INVISIBLE.

You can insert and update values in the start time column and end time column as you would any column, with the following considerations:

- If the value of the start time column is NULL, then the row is considered valid for all time values that occur before, but not including, the value of the end time column.
- If the value of the end time column is NULL, then the row is considered valid for all time values that occur on or after the value of the start time column.
- If the value of neither column is NULL, then the value of the start time column must be earlier than the value of the end time column. The row is considered valid for all time values that occur on or after the value of the start time column, and up to, but not including, the value of the end time column.
- If the value of both columns is NULL, then the row is considered valid for all time values.

Restrictions on Valid Time Dimension Columns

The following restrictions apply to valid time dimension columns:

- The *valid_time_column* is for internal use only. You cannot perform DDL or DML operations on it with one exception: You can drop the column by using the *drop_period_clause* of ALTER TABLE.
- You can drop the start time column and end time column only by using the *drop_period_clause* of ALTER TABLE.
- If the start time column and end time column are automatically created by Oracle Database, then they are INVISIBLE and you cannot subsequently make them VISIBLE.

> **See Also:**
>
> - *Oracle Database Development Guide* for more information on Temporal Validity
> - `SELECT` *flashback_query_clause* for more information on Oracle Flashback Query
> - `ALTER TABLE` *add_period_clause* and *drop_period_clause* for information how to add and drop a valid time dimension

Constraint Clauses

Use these clauses to create constraints on the table columns. You must specify a `PRIMARY KEY` constraint for an index-organized table, and it cannot be `DEFERRABLE`. Refer to *constraint* for syntax and description of these constraints as well as examples.

inline_ref_constraint* and *out_of_line_ref_constraint

These clauses let you describe a column of type `REF`. The only difference between these clauses is that you specify *out_of_line_ref_constraint* from the table level, so you must identify the `REF` column or attribute you are defining. Specify *inline_ref_constraint* as part of the definition of the `REF` column or attribute.

> **See Also:**
>
> "REF Constraint Examples"

inline_constraint

Use the *inline_constraint* to define an integrity constraint as part of the column definition.

You can create `UNIQUE`, `PRIMARY KEY`, and `REFERENCES` constraints on scalar attributes of object type columns. You can also create `NOT NULL` constraints on object type columns and `CHECK` constraints that reference object type columns or any attribute of an object type column.

out_of_line_constraint

Use the *out_of_line_constraint* syntax to define an integrity constraint as part of the table definition.

supplemental_logging_props

The *supplemental_logging_props* clause lets you instruct the database to put additional data into the log stream to support log-based tools.

supplemental_log_grp_clause

Use this clause to create a named log group.

- The `NO LOG` clause lets you omit from the redo log one or more columns that would otherwise be included in the redo for the named log group. You must specify at least one fixed-length column without `NO LOG` in the named log group.
- If you specify `ALWAYS`, then during an update, the database includes in the redo all columns in the log group. This is called an **unconditional log group** (sometimes called an "always log group"), because Oracle Database supplementally logs all the columns in the log group

when the associated row is modified. If you omit `ALWAYS`, then the database supplementally logs all the columns in the log group only if any column in the log group is modified. This is called a **conditional log group**.

You can query the appropriate `USER_`, `ALL_`, or `DBA_LOG_GROUP_COLUMNS` data dictionary view to determine whether any supplemental logging has already been specified.

supplemental_id_key_clause

Use this clause to specify that all or a combination of the primary key, unique key, and foreign key columns should be supplementally logged. Oracle Database will generate either an **unconditional log group** or a **conditional log group**. With an unconditional log group, the database supplementally logs all the columns in the log group when the associated row is modified. With a conditional log group, the database supplementally logs all the columns in the log group only if any column in the log group is modified.

- If you specify `ALL COLUMNS`, then the database includes in the redo log all the fixed-length maximum size columns of that row. Such a redo log is a system-generated unconditional log group.
- If you specify `PRIMARY KEY COLUMNS`, then for all tables with a primary key, the database places into the redo log all columns of the primary key whenever an update is performed. Oracle Database evaluates which columns to supplementally log as follows:
  - First the database chooses columns of the primary key constraint, if the constraint is validated or marked `RELY` and is not marked as `DISABLED` or `INITIALLY DEFERRED`.
  - If no primary key columns exist, then the database looks for the smallest `UNIQUE` index with at least one `NOT NULL` column and uses the columns in that index.
  - If no such index exists, then the database supplementally logs all scalar columns of the table.
- If you specify `UNIQUE COLUMNS`, then for all tables with a unique key or a bitmap index, if any of the unique key or bitmap index columns are modified, the database places into the redo log all other columns belonging to the unique key or bitmap index. Such a log group is a system-generated conditional log group.
- If you specify `FOREIGN KEY COLUMNS`, then for all tables with a foreign key, if any foreign key columns are modified, the database places into the redo log all other columns belonging to the foreign key. Such a redo log is a system-generated conditional log group.

If you specify this clause multiple times, then the database creates a separate log group for each specification. You can query the appropriate `USER_`, `ALL_`, or `DBA_LOG_GROUPS` data dictionary view to determine whether any supplemental logging data has already been specified.

immutable_table_clauses

You must specify this clause when you create an immutable table.

If you do not specify the `VERSION` using *`immutable_data_format_clause`*, a `V1` immutable table is created by default.

Example: Create an Immutable Table

The following example creates an immutable table named *`trade_ledger`* in your user schema. The immutable table can be dropped only after 40 days of inactivity. Rows cannot be deleted until 100 days after they have been inserted.

```
CREATE IMMUTABLE TABLE trade_ledger (tr_id NUMBER, user_name VARCHAR2(40), tr_value
```

```
NUMBER)

       NO DROP UNTIL 40 DAYS IDLE

       NO DELETE UNTIL 100 DAYS AFTER INSERT;
```

blockchain_table_clauses

When you create a blockchain table, you must specify the *blockchain_table_clauses*:

- *blockchain_drop_table_clause*
- *blockchain_row_retention_clause*
- *blockchain_hash_clause*
- *blockchain_data_format_clause*

blockchain_drop_table_clause

```
NO DROP [ UNTIL integer DAYS IDLE ]
```

Use `integer` to specify the number of days that the blockchain table must be idle (i.e. have no rows inserted). The minimum idle retention period is 0 days, but the recommended idle retention period is 16 days.

You can specify this clause in two ways:

- `NO DROP` means that the blockchain table cannot be dropped.
- `NO DROP UNTIL integer DAYS IDLE` means that the blockchain table cannot be dropped, if the newest row is less than `integer` of days old.

blockchain_row_retention_clause

```
NO DELETE [ LOCKED ]
  | NO DELETE UNTIL integer DAYS AFTER INSERT [LOCKED]
```

- `integer` specifies the idle retention period for inserted rows before they can be deleted. The minimum idle retention period for inserted rows is 16 days.
- If you specify `LOCKED`, then you cannot change the retention period using `ALTER TABLE`.
- If you do not specify `LOCKED` in the clause `UNTIL number DAYS AFTER INSERT`, then you can change the retention period using `ALTER TABLE`, but only to a value higher than the previous retention period.
- If you specify `NO DELETE LOCKED`, then you cannot delete any rows from this table. But you can drop the entire table if the table is inactive for more than the number of days specified in the *blockchain_drop_table_clause*.

blockchain_hash_clause

```
HASHING USING sha2_512
```

You must specify this clause last after *blockchain_drop_table_clause* and *blockchain_row_retention_clause* when you create a blockchain table.

You cannot specify this clause to modify a blockchain table using the `ALTER TABLE` statement.

blockchain_row_version_user_chain_clause

WITH ROW VERSION

This clause is optional and can only be specified on VERSION V2 blockchain tables. You can specify at most three user-defined columns with the clause. The name of the row version sequence identified by *row_version_name* is used to verify the user chain. The types of the columns are restricted to NUMBER, CHAR, VARCHAR2, and RAW. When the clause is specified, rows with identical values in the specified user-defined columns are sequenced using the Oracle managed hidden column ORABCTAB_ROW_VERSION$.

Example: Row Versions

```
CREATE BLOCKCHAIN TABLE bank_ledger (bank VARCHAR2(128), account_no NUMBER, deposit_date
DATE, deposit_amount NUMBER)
  NO DROP UNTIL 31 DAYS IDLE
  NO DELETE LOCKED
  HASHING USING SHA2_512 WITH ROW VERSION ACCOUNT_NO (bank, account_no) VERSION V2;
```

AND USER CHAIN

The optional AND USER CHAIN clause can only be specified on VERSION V2 blockchain tables as part of the WITH ROW VERSION clause. It extends the functionality offered by the row versions and links these rows in a separate (user) blockchain. At most three user-defined columns can be specified to define a user chain. The name of the user chain is that specified in the WITH ROW VERSION clause. The sequencing of the rows in the user chain is accomplished using column ORABCTAB_ROW_VERSION$. The crypto hash is maintained in column ORABCTAB_USER_CHAIN_HASH$. Note, that ORABCTAB_USER_CHAIN_HASH$ is not signed in V2 blockchain tables. Only the system crypto hash can be signed (with signature stored in ORABCTAB_SIGNATURE$ or ORABCTAB_DELEGATE_SIGNATURE$ column).

Example: AND USER CHAIN

```
CREATE BLOCKCHAIN TABLE bank_ledger (bank VARCHAR2(128), account_no NUMBER, deposit_date
DATE, deposit_amount NUMBER)
         NO DROP UNTIL 31 DAYS IDLE
         NO DELETE LOCKED
         HASHING USING SHA2_512 WITH ROW VERSION AND USER CHAIN bank_accounts (bank,
account_no) VERSION V2;
```

blockchain_system_chains_clause

Specify this clause to override the default of 32 system chains per instance. The number of system chains configured by this clause must be between 1 and 1024.

blockchain_data_format_clause

You must specify the version when you create a blockchain table, either V1 or V2. Version V2 creates additional Oracle managed hidden columns than V1.

You cannot use ALTER TABLE to convert version from V1 to V2 and vice versa.

Example: HASHING and VERSION

```
CREATE BLOCKCHAIN TABLE bank_ledger (bank VARCHAR2(128), deposit_date DATE,
deposit_amount NUMBER)
  NO DROP UNTIL 31 DAYS IDLE
  NO DELETE LOCKED
  HASHING USING SHA2_512 VERSION V2;
```

DEFAULT COLLATION

This clause lets you specify the default collation for the table. The default collation is assigned to columns of the table that are of a character data type and are created with this statement or subsequently added to the table with an `ALTER TABLE` statement. For *`collation_name`*, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the table is set to the effective schema default collation of the schema containing the table. Refer to the DEFAULT_COLLATION clause of `ALTER SESSION` for more information on the effective schema default collation.

You can override the table's default collation and assign a data-bound collation to a particular column by specifying the `COLLATE` clause in the *`column_definition`* or *`virtual_column_definition`* clause of `CREATE TABLE` or `ALTER TABLE`, or the *`modify_col_properties`* or *`modify_virtcol_properties`* clause of `ALTER TABLE`.

You can specify the `DEFAULT COLLATION` clause only if the `COMPATIBLE` initialization parameter is set to `12.2` or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

Restriction on Collation for CLOB and NCLOB Columns

If a column has the data type of `CLOB` or `NCLOB`, then its specified collation must be `USING_NLS_COMP`. The collation of `CLOB` and `NCLOB` columns is always `USING_NLS_COMP` and is not affected by the default collation for the table.

> **See Also:**
>
> *Oracle Database Globalization Support Guide* for full information on default collations and data-bound collations

ON COMMIT

The `ON COMMIT` clause is relevant only if you are creating a global temporary table. This clause specifies whether the data in the temporary table persists for the duration of a transaction or a session.

DELETE ROWS

Specify `DELETE ROWS` for a transaction-specific temporary table. This is the default. Oracle Database will truncate the table (delete all its rows) after each commit.

PRESERVE ROWS

Specify `PRESERVE ROWS` for a session-specific temporary table. Oracle Database will truncate the table (delete all its rows) when you terminate the session.

You can define the scope of a private temporary table using `ON COMMIT`. Use `DROP DEFINITION` to define a transaction-specific table and `PRESERVE DEFINITION` to define a session-specific table .

DROP DEFINITION

Specify `DROP DEFINITION` to create a private temporary table whose content and definition are dropped when the transaction commits. The creation of a transaction-specific private temporary table does not issue an implicit commit, but can be issued within an ongoing

transaction. The scope of this private temporary table is limited to the ongoing transaction. The scope of this private temporary table is limited to the transaction. This is the default.

PRESERVE DEFINITION

Specify `PRESERVE DEFINITION` to create a private temporary table whose definition is preserved when the transaction commits. The creation of a session-specific private temporary table issues an implicit commit. The scope of this private temporary table is extended to the session.

physical_properties

The physical properties relate to the treatment of extents and segments and to the storage characteristics of the table.

INTERNAL | EXTERNAL
Use the keyword `INTERNAL` to indicate an internal partition. This is the default. Use the keyword `EXTERNAL` to indicate an external partition.

deferred_segment_creation

Use this clause to determine when the database should create the segment(s) for this table:

- `SEGMENT CREATION DEFERRED`: This clause defers creation of the table segment — as well as segments for any LOB columns of the table, any indexes created implicitly as part of table creation, and any indexes subsequently explicitly created on the table — until the first row of data is inserted into the table. At that time, the segments for the table, LOB columns and indexes, and explicitly created indexes are all materialized and inherit any storage properties specified in this `CREATE TABLE` statement or, in the case of explicitly created indexes, the `CREATE INDEX` statement. These segments are created regardless whether the initial insert operation is uncommitted or rolled back. This is the default value.

  > **Caution:**
  >
  > When creating many tables with deferred segment creation, ensure that you allocate enough space for your database so that when the first rows are inserted, there is enough space for all the new segments.

- `SEGMENT CREATION IMMEDIATE`: The table segment is created as part of this `CREATE TABLE` statement.

Immediate segment creation is useful, for example, if your application depends upon the object appearing in the `DBA_`, `USER_`, and `ALL_SEGMENTS` data dictionary views, because the object will not appear in those views until the segment is created. This clause overrides the setting of the `DEFERRED_SEGMENT_CREATION` initialization parameter.

To determine whether a segment has been created for an existing table or its LOB columns or indexes, query the `SEGMENT_CREATED` column of `USER_TABLES`, `USER_INDEXES`, or `USER_LOBS`.

Notes on Tables Without Segments

The following rules apply to a table whose segment has not yet been materialized:

- If you create this table with `CREATE TABLE ... AS` *`subquery`*, then if the source table has no rows, segment creation of the new table is deferred. If the source table has rows, then segment creation of the new table is not deferred.

- If you specify `ALTER TABLE ... ALLOCATE EXTENT` before the segment is materialized, then the segment is materialized and then an extent is allocated. However the `ALLOCATE EXTENT` clause in a DDL statement on any indexes of the table will return an error.
- In a DDL statement on the table or its LOB columns or indexes, any specification of `DEALLOCATE UNUSED` is silently ignored.
- `ONLINE` operations on indexes of a table or table partition without a segment will silently be disabled; that is, they will proceed `OFFLINE`.
- If any of the following DDL statements are executed on a table with one or more LOB columns, then the resulting partition(s) or subpartition(s) will be materialized:
  - `ALTER TABLE SPLIT [SUB]PARTITION`
  - `ALTER TABLE MERGE [SUB]PARTITIONS`
  - `ALTER TABLE ADD [SUB]PARTITION` (hash partitions only)
  - `ALTER TABLE COALESCE [SUB]PARTITION` (hash partitions only)

Restrictions on Deferred Segment Creation

This clause is subject to the following restrictions:

- You cannot defer segment creation for the following types of tables: clustered tables, global temporary tables, session-specific temporary tables, internal tables, external tables, and tables owned by `SYS`, `SYSTEM`, `PUBLIC`, `OUTLN`, or `XDB`.
- Deferred segment creation is not supported in dictionary-managed tablespaces.
- Deferred segment creation is not supported in the `SYSTEM` tablespace.
- Serializable transactions do not work with deferred segment creation. Trying to insert data into an empty table with no segment created causes an error.

> **See Also:**
>
> *Oracle Database Concepts* for general information on segment allocation and *Oracle Database Reference* for more information about the `DEFERRED_SEGMENT_CREATION` initialization parameter

segment_attributes_clause

The *`segment_attributes_clause`* lets you specify physical attributes and tablespace storage for the table.

physical_attributes_clause

The *`physical_attributes_clause`* lets you specify the value of the `PCTFREE`, `PCTUSED`, and `INITRANS` parameters and the storage characteristics of the table.

- For a nonpartitioned table, each parameter and storage characteristic you specify determines the actual physical attribute of the segment associated with the table.
- For partitioned tables, the value you specify for the parameter or storage characteristic is the default physical attribute of the segments associated with all partitions specified in this `CREATE` statement (and in subsequent `ALTER TABLE ... ADD PARTITION` statements), unless you explicitly override that value in the `PARTITION` clause of the statement that creates the partition.

If you omit this clause, then Oracle Database sets PCTFREE to 10, PCTUSED to 40, and INITRANS to 1.

> **See Also:**
>
> - *physical_attributes_clause* and storage_clause for a description of these clauses
> - "Creating a Table: Storage Example"

TABLESPACE

Specify the tablespace in which Oracle Database creates the table, object table OIDINDEX, partition, LOB data segment, LOB index segment, or index-organized table overflow data segment. If you omit TABLESPACE, then the database creates that item in the default tablespace of the owner of the schema containing the table.

For a heap-organized table with one or more LOB columns, if you omit the TABLESPACE clause for LOB storage, then the database creates the LOB data and index segments in the tablespace where the table is created.

For an index-organized table with one or more LOB columns, if you omit TABLESPACE, then the LOB data and index segments are created in the tablespace in which the primary key index segment of the index-organized table is created.

For nonpartitioned tables, the value specified for TABLESPACE is the actual physical attribute of the segment associated with the table. For partitioned tables, the value specified for TABLESPACE is the default physical attribute of the segments associated with all partitions specified in the CREATE statement and on subsequent ALTER TABLE ... ADD PARTITION statements, unless you specify TABLESPACE in the PARTITION description.

> **See Also:**
>
> CREATE TABLESPACE for more information on tablespaces

TABLESPACE SET

This clause is valid only when creating a sharded table by specifying the SHARDED keyword of CREATE TABLE. Use this clause to specify the tablespace set in which Oracle Database creates the table.

You can only associate a tablespace set with one table family when you use the CREATE SHARDED TABLE statement. If you try to use a tablespace set with more than one table family, an error will be thrown .

logging_clause

Specify whether the creation of the table and of any indexes required because of constraints, partition, or LOB storage characteristics will be logged in the redo log file (LOGGING) or not (NOLOGGING).The logging attribute of the table is independent of that of its indexes.

This attribute also specifies whether subsequent direct loader (SQL*Loader) and direct-path INSERT operations against the table, partition, or LOB storage are logged (LOGGING) or not logged (NOLOGGING).

Refer to *logging_clause* for a full description of this clause.

table_compression

The *table_compression* clause is valid only for heap-organized tables. Use this clause to instruct the database whether to compress data segments to reduce disk use. The COMPRESS clauses enable table compression. The NOCOMPRESS clause disables table compression. The default is NOCOMPRESS.

COMPRESS

Specifying only the keyword COMPRESS is equivalent to specifying ROW STORE COMPRESS BASIC and enables basic table compression.

ROW STORE COMPRESS BASIC

When you enable table compression by specifying either ROW STORE COMPRESS or ROW STORE COMPRESS BASIC, you enable **basic table compression**. Oracle Database attempts to compress data during direct-path INSERT operations when it is productive to do so. The original import utility (imp) does not support direct-path INSERT, and therefore cannot import data in a compressed format.

Tables with basic table compression use a PCTFREE value of 0 to maximize compression, unless you explicitly set a value for PCTFREE in the *physical_attributes_clause*.

In earlier releases, basic table compression was enabled using COMPRESS BASIC. This syntax is still supported for backward compatibility.

> **See Also:**
>
> "Conventional and Direct-Path INSERT" for information on direct-path INSERT operations, including restrictions

ROW STORE COMPRESS ADVANCED

When you enable table compression by specifying ROW STORE COMPRESS ADVANCED, you enable **Advanced Row Compression**. Oracle Database compresses data during all DML operations on the table. This form of compression is recommended for OLTP environments.

Tables with ROW STORE COMPRESS ADVANCED or NOCOMPRESS use the PCTFREE default value of 10, to maximize compress while still allowing for some future DML changes to the data, unless you override this default explicitly.

In earlier releases, Advanced Row Compression was called OLTP table compression and was enabled using COMPRESS FOR OLTP. This syntax is still supported for backward compatibility.

COLUMN STORE COMPRESS FOR { QUERY | ARCHIVE }

When you specify COLUMN STORE COMPRESS FOR QUERY or COLUMN STORE COMPRESS FOR ARCHIVE, you enable **Hybrid Columnar Compression**. With Hybrid Columnar Compression, data can be compressed during direct-path inserts, conventional inserts, and array inserts. During the load process, data is transformed into a column-oriented format and then compressed. Oracle Database uses a compression algorithm appropriate for the level you specify. In general, the higher the level, the greater the compression ratio. Hybrid Columnar Compression can result in higher compression ratios, at a greater CPU cost. Therefore, this form of compression is recommended for data that is not frequently updated.

COLUMN STORE COMPRESS FOR QUERY is useful in data warehousing environments. Valid values are LOW and HIGH, with HIGH providing a higher compression ratio. The default is HIGH.

COLUMN STORE COMPRESS FOR ARCHIVE uses higher compression ratios than COLUMN STORE COMPRESS FOR QUERY, and is useful for compressing data that will be stored for long periods of time. Valid values are LOW and HIGH, with HIGH providing the highest possible compression ratio. The default is LOW.

Specifying COLUMN STORE COMPRESS is equivalent to specifying COLUMN STORE COMPRESS FOR QUERY HIGH.

Tables with COLUMN STORE COMPRESS FOR QUERY or COLUMN STORE COMPRESS FOR ARCHIVE use a PCTFREE value of 0 to maximize compression, unless you explicitly set a value for PCTFREE in the *physical_attributes_clause*. For these tables, PCTFREE has no effect for blocks loaded using direct-path INSERT. PCTFREE is honored for blocks loaded using conventional INSERT, and for blocks created as a result of DML operations on blocks originally loaded using direct-path INSERT.

[NO] ROW LEVEL LOCKING

If you specify ROW LEVEL LOCKING, then Oracle Database uses row-level locking during DML operations. This improves the performance of these operations when accessing Hybrid Columnar Compressed data. If you specify NO ROW LEVEL LOCKING, then row-level locking is not used. The default is NO ROW LEVEL LOCKING.

In earlier releases, Hybrid Columnar Compression was enabled using COMPRESS FOR QUERY and COMPRESS FOR ARCHIVE. This syntax is still supported for backward compatibility.

> **See Also:**
>
> *Oracle Database Concepts* for more information on Hybrid Columnar Compression, which is a feature of certain Oracle storage systems

Notes on Table Compression

You can specify table compression for the following portions of a heap-organized table:

- For an entire table, in the *physical_properties* clause of *relational_table* or *object_table*
- For a range partition, in the *table_partition_description* of the *range_partitions* clause
- For a composite range partition, in the *table_partition_description* of the *range_partition_desc* clause
- For a composite list partition, in the *table_partition_description* of the *list_partition_desc* clause
- For a list partition, in the *table_partition_description* of the *list_partitions* clause
- For a system or reference partition, in the *table_partition_description* of the *reference_partition_desc* clause
- For the storage table of a nested table, in the *nested_table_col_properties* clause

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_COMPRESSION` package, which helps you choose the correct compression level for an application, and *Oracle Database Administrator's Guide* for more information about table compression, including examples

Restrictions on Table Compression

Table compression is subject to the following restrictions:

- Data segments of BasicFiles LOBs are not compressed. For information on compression of SecureFiles LOBs, see LOB_compression_clause.
- You cannot drop a column from a table that uses compression, although you can set such a column as unused. All of the operations of the `ALTER TABLE ... drop_column_clause` are valid for tables that use `ROW STORE COMPRESS ADVANCED`, `COLUMN STORE COMPRESS FOR QUERY`, and `COLUMN STORE COMPRESS FOR ARCHIVE`.
- You cannot specify any type of table compression for an index-organized table, any overflow segment or partition of an overflow segment, or any mapping table segment of an index-organized table.
- You cannot specify any type of table compression for external tables or for tables that are part of a cluster.
- You cannot specify any type of table compression for tables with `LONG` or `LONG RAW` columns, tables that are owned by the `SYS` schema and reside in the `SYSTEM` tablespace, or tables with `ROWDEPENDENCIES` enabled.
- You cannot specify Hybrid Columnar Compression on tables that are enabled for flashback archiving.
- You cannot specify Hybrid Columnar Compression on the following object-relational features: object tables, `XMLType` tables, columns with abstract data types, collections stored as tables, or OPAQUE types, including `XMLType` columns stored as objects.
- When you update a row in a table compressed with Hybrid Columnar Compression, the `ROWID` of the row may change.
- In tables compressed with Hybrid Columnar Compression, updates to a single row may result in locks on multiple rows. Concurrency for write transactions may therefore be affected.
- If a table compressed with Hybrid Columnar Compression has a foreign key constraint, and you insert data using `INSERT` with the `APPEND` hint, then the data will be compressed to a lesser level than is typical with Hybrid Columnar Compression. To compress the data with Hybrid Columnar Compression, disable the foreign key constraint, insert the data using `INSERT` with the `APPEND` hint, and then reenable the foreign key constraint.

inmemory_table_clause

Use this clause to enable or disable the table for the In-Memory Column Store (IM column store). The IM column store is an optional, static SGA pool that stores copies of tables and partitions in a special columnar format optimized for rapid scans. The IM column store does not replace the buffer cache, but acts as a supplement so that both memory areas can store the same data in different formats.

- Specify `INMEMORY` to enable the table for the IM column store.

You can optionally use the *inmemory_attributes* clause to specify how table data is stored in the IM column store. This clause enables you to specify the data compression method and the data population priority. In an Oracle RAC environment, it also enables you to specify how the data is distributed and duplicated across Oracle RAC instances. Refer to the *inmemory_attributes* clause for more information.

- Specify `NO INMEMORY` to disable the table for the IM column store.
- Specify the *inmemory_column_clause* to enable or disable specific table columns for the IM column store, and to specify the data compression method for specific columns. Refer to the *inmemory_clause* for more information.
- Specify `INMEMORY ALL` to mark all columns as in-memory. Specify `NO INMEMORY ALL` to mark all columns as not in-memory. These options are applied first to table columns before other inmemory column clauses.

  You cannot specify `INMEMORY ALL` and `NO INMEMORY ALL` in the same DDL.

If you omit this clause, then the table is assigned the default IM column store settings for the tablespace in which it is created. Refer to the *inmemory_clause* of `CREATE TABLESPACE` for more information on specifying the default IM column store settings for a tablespace.

In an Oracle Active Data Guard environment, if you specify this clause for a table on the primary database, then the table is enabled or disabled for the IM column store in the Oracle Active Data Guard instance.

> **Note:**
>
> The `INMEMORY_CLAUSE_DEFAULT` initialization parameter enables you to specify a default IM column store clause for new tables and materialized views. Refer to *Oracle Database Reference* for more information on the `INMEMORY_CLAUSE_DEFAULT` initialization parameter.

Restrictions on the In-Memory Column Store

The following restrictions apply to the In-Memory Column Store:

- You cannot specify the `INMEMORY` clause for index-organized tables.
- You cannot specify the `INMEMORY` clause for tables that are owned by the `SYS` schema and reside in the `SYSTEM` or `SYSAUX` tablespace.
- Starting with Oracle Database 18*c* , you can specify the `INMEMORY` clause for external tables. You must set the `QUERY_REWRITE_INTEGRITY` initialization parameter to `stale_tolerated` for the DDL to parse correctly. The policy may not be changed via `ALTER` to anything other than `stale_tolerated` if `INMEMORY` is specified.
- The IM column store does not support `LONG` or `LONG RAW` columns, out-of-line columns (LOBs, varrays, nested table columns), or extended data type columns. If you enable a table for the IM column store and it contains any of these types of columns, then the columns will not be populated in the IM column store.
- If you enable a table for the IM column store and it contains a virtual (expression) column, then the column will be populated in the IM column store only if the value of the `INMEMORY_VIRTUAL_COLUMNS` initialization parameter is `ENABLED` and the SQL expression for the virtual (expression) column refers only to columns that are enabled for the IM column store.

> **See Also:**
>
> *Oracle Database In-Memory Guide* for an overview of the IM column store

inmemory_attributes

Use the *inmemory_memcompress*, *inmemory_priority*, *inmemory_distribute*, and *inmemory_duplicate* clauses to specify how table data is stored in the IM column store.

Specify the *inmemory_spatial* clause to apply inmemory attributes to spatial columns of type SDO_GEOMETRY.

inmemory_memcompress

Use this clause to specify the compression method for table data stored in the IM column store. This data is called In-Memory data.

To instruct the database to not compress In-Memory data, specify NO MEMCOMPRESS.

Specify MEMCOMPRESS AUTO to instruct the database to manage the segment including actions like evict, recompress, and populate.

To instruct the database to compress In-Memory data, specify MEMCOMPRESS FOR followed by one of the following methods:

- DML - This method is optimized for DML operations and performs little or no data compression.
- QUERY - Specifying QUERY is equivalent to specifying QUERY LOW.
- QUERY LOW - This method compresses In-Memory data the least (except for DML) and results in the best query performance. This is the default.
- QUERY HIGH -This method compress In-Memory data more than QUERY LOW, but less than CAPACITY LOW.
- CAPACITY - Specifying CAPACITY is equivalent to specifying CAPACITY LOW.
- CAPACITY LOW - This method compresses In-Memory data more than QUERY HIGH, but less than CAPACITY HIGH, and results in excellent query performance.
- CAPACITY HIGH - This method compresses In-Memory data the most and results in good query performance.

Any memcompress level can be specified via DDL, but will be ignored during population. All In-Memory Compression Units (IMCUs) will be populated as QUERY LOW transparently.

inmemory_priority

Use the PRIORITY clause to specify the data population priority for table data in the IM column store. This clause controls the priority of population, but not the speed of population.

- Specify NONE for **on-demand population**. In this case, the database populates table data in the IM column store when the table it is accessed through a full table scan. If the table is never accessed, or if it is accessed only through an index scan or fetch by rowid, then population never occurs. This is the default.
- Specify one of the following priority levels for **priority-based population**: LOW, MEDIUM, HIGH, or CRITICAL. In this case, the database automatically populates table data in the IM

column store using an internally managed priority queue; a full scan is not a necessary condition for population. The database queues population of the table data based on the specified priority level. For example, a table with the setting `INMEMORY PRIORITY CRITICAL` takes precedence over a table with the setting `INMEMORY PRIORITY HIGH`, which in turn takes precedence over a table with the setting `INMEMORY PRIORITY LOW`, and so on. If the IM column store has insufficient space, then the database does not populate additional table data until space is available.

inmemory_distribute

The `DISTRIBUTE` clause is applicable only if you are using Oracle Real Application Clusters (Oracle RAC) or Oracle Active Data Guard. It lets you specify how table data in the IM column store is distributed across Oracle RAC instances, and lets you specify the database instances in which the data is eligible to be populated.

AUTO and BY

Use the `AUTO` and `BY` clauses to specify how table data in the IM column store is distributed across Oracle RAC instances. You can specify the following options:

- `AUTO` - Oracle Database controls how data is distributed across Oracle RAC instances. Large tables are distributed across Oracle RAC instances depending on their access patterns. Smaller tables may be distributed between instances. This is the default.
- `BY ROWID RANGE` - Data in certain ranges of rowids is distributed to different Oracle RAC instances.
- `BY PARTITION` - Data in partitions is distributed to different Oracle RAC instances.
- `BY SUBPARTITION` - Data in subpartitions is distributed to different Oracle RAC instances.

You can only use `AUTO` and `BY` to distribute the In-Memory Compression Units (IMCUs) for an object between instances in a single Oracle RAC database, not between a primary instance and standby instance in Active Data Guard.

FOR SERVICE

Use the `FOR SERVICE` clause to specify the Oracle RAC or Oracle Active Data Guard instances in which the object is eligible to be populated. You can specify the following options:

- `DEFAULT` - The object is eligible for population on all instances specified with the `PARALLEL_INSTANCE_GROUP` initialization parameter. If this parameter is not set, then the object is populated on all instances. This is the default.
- `ALL` - The object is eligible for population on all instances, regardless of the value of the `PARALLEL_INSTANCE_GROUP` initialization parameter.
- *`service_name`* - The object is eligible for population only on instances belonging to the specified service and only when the service is active and not blocked on an instance.
- `NONE` - The object is not eligible for population on any instances. This option lets you disable IM column store population while preserving the other In-Memory attributes for the table. These attributes take effect if you subsequently enable IM column store population for the table by specifying `FOR SERVICE DEFAULT`, `FOR SERVICE ALL`, or `FOR SERVICE` *`service_name`* in the *`inmemory_distribute`* clause of an `ALTER TABLE` statement.

In Oracle RAC, the `FOR SERVICE` clause specifies the instances within the Oracle RAC database. In Active Data Guard, the primary and standby databases may use a single-instance or Oracle RAC configuration. In Active Data Guard, the `FOR SERVICE` clause specifies instances in the primary database, instances in the standby database, or a mixture of primary and standby instances.

inmemory_duplicate

The DUPLICATE clause is applicable only if you are using Oracle Real Application Clusters (Oracle RAC) on an engineered system. It controls how table data in the IM column store is duplicated across Oracle RAC instances. You can specify the following options:

- DUPLICATE - Data is duplicated on one Oracle RAC instance, resulting in the data existing on a total of two Oracle RAC instances.
- DUPLICATE ALL - Data is duplicated across all Oracle RAC instances. If you specify DUPLICATE ALL, then the database uses the DISTRIBUTE AUTO setting, regardless of whether or how you specify the *inmemory_distribute* clause.
- NO DUPLICATE - Data is not duplicated across Oracle RAC instances. This is the default.

inmemory_column_clause

Use this clause to enable or disable specific table columns for the IM column store, and to specify the data compression method for specific columns. If you specify this clause when creating a NO INMEMORY table, then the column settings will take effect when the table or partition is subsequently enabled for the IM column store.

- Specify INMEMORY to enable the specified table columns for the IM column store.

  You can optionally use the *inmemory_memcompress* clause to specify the data compression method for specific columns. See *inmemory_memcompress*. If you omit the *inmemory_memcompress* clause, then the table column uses the data compression method for the table. You cannot specify the PRIORITY, DISTRIBUTE, or DUPLICATE settings for a specific table column. These settings are the same for all table columns as they are for the table.
- Specify NO INMEMORY to disable the specified table columns for the IM column store.

If you omit the *inmemory_column_clause*, then all table columns use the IM column store settings for the table.

Restrictions on *inmemory_column_clause*

- You cannot specify this clause for a LONG or LONG RAW column, an out-of-line column (LOB, varray, nested table column), or an extended data type column.
- To selectively enable a virtual (expression) column for the IM column store, the value of the INMEMORY_VIRTUAL_COLUMNS initialization parameter must be ENABLED or MANUAL, and the SQL expression for the virtual (expression) column must refer only to columns that are enabled for the IM column store.

inmemory_clause

Use this clause to enable or disable a table partition for the IM column store. In order to specify this clause, the table must be enabled for the IM column store. If you omit this clause, then the table partition uses the IM column store settings for the table.

The *inmemory_attributes* clause has the same semantics for table partitions as for tables. Refer to the *inmemory_attributes* clause for full information.

INMEMORY TEXT

Specify INMEMORY TEXT clause to enable IM full text columns. The PRIORITY clause has the same effect on population of IM full text columns as standard In-Memory columns. The default priority is NONE.

The MEMCOMPRESS clause is not valid with INMEMORY TEXT.

Examples

```
CREATE TABLE mydoc(id NUMBER, docCreationTime DATE, doc CLOB, json_doc JSON) INMEMORY
TEXT(DOC, JSON_DOC)

CREATE TABLE mydoc(id NUMBER, docCreationTime DATE, doc CLOB, json_doc JSON) INMEMORY
PRIORITY CRITICAL
    INMEMORY TEXT(DOC, JSON_DOC)
```

You can apply the IMEMORY TEXT clause to search non-scalar columns in an In-Memory table. This clause enables fast In-Memory searching of text, XML, or JSON documents using the CONTAINS () or JSON_TEXTCONTAINS() operators.

INMEMORY TEXT (column_name1, column_name2) specifies the list of columns to be enabled as IM full text. The columns must be of type CHAR, VARCHAR2, CLOB, BLOB, or JSON. JSON columns have JSON_TEXTCONTAINS() automatically enabled.

INMEMORY TEXT (column_name1 USING policy1, column_name2 USING policy2) specifies the list of columns to be enabled as IM full text along with custom indexing policies. The columns must be of type CHAR, VARCHAR2, CLOB, or BLOB. You cannot use this clause with columns of type JSON.

You can use the IMEMORY PRIORITY clause to set the order in which objects are populated.

> **See Also:**
>
> IM Full Text Columns.

You can specify INMEMORY on non-partitioned tables using the ORACLE_HIVE, ORACLE_HDFS, and ORACLE_BIGDATA driver types.

ilm_clause

Use this clause to add an Automatic Data Optimization policy to *table*.

This clause has the same semantics in CREATE TABLE and ALTER TABLE, with the following additional restriction: You can specify only the ADD POLICY clause for CREATE TABLE. Refer to the *ilm_clause* for the full semantics of this clause.

> **See Also:**
>
> *Oracle Database VLDB and Partitioning Guide* for more information on managing policies for Automatic Data Optimization

Restrictions on Automatic Data Optimization

Automatic Data Optimization is subject to the following restrictions:

- Automatic Data Optimization is not supported for tables that contain object types, index-organized tables, clustered tables, or materialized views.

- Row-level policies are not supported for tables that support Temporal Validity or tables that are enabled for row archiving for In-Database Archiving.

ilm_policy_clause

Use this clause to describe the Automatic Data Optimization policy.

This clause has the same semantics in `CREATE TABLE` and `ALTER TABLE`. Refer to *ilm_policy_clause* for the full semantics of this clause.

RECOVERABLE | UNRECOVERABLE

These keywords are deprecated and have been replaced with `LOGGING` and `NOLOGGING`, respectively. Although `RECOVERABLE` and `UNRECOVERABLE` are supported for backward compatibility, Oracle strongly recommends that you use the `LOGGING` and `NOLOGGING` keywords.

Restrictions on [UN]RECOVERABLE

This clause is subject to the following restrictions:

- You cannot specify `RECOVERABLE` for partitioned tables or LOB storage characteristics.
- You cannot specify `UNRECOVERABLE` for partitioned or index-organized tables.
- You can specify `UNRECOVERABLE` only with `AS` *`subquery`*.

ORGANIZATION

The `ORGANIZATION` clause lets you specify the order in which the data rows of the table are stored.

HEAP

`HEAP` indicates that the data rows of *`table`* are stored in no particular order. This is the default.

INDEX

`INDEX` indicates that *`table`* is created as an index-organized table. In an index-organized table, the data rows are held in an index defined on the primary key for the table.

EXTERNAL

`EXTERNAL` indicates that table is a read-only table located outside the database.

> **See Also:**
>
> "External Table Example"

index_org_table_clause

Use the *`index_org_table_clause`* to create an index-organized table. Oracle Database maintains the table rows, both primary key column values and nonkey column values, in an index built on the primary key. Index-organized tables are therefore best suited for primary key-based access and manipulation. An index-organized table is an alternative to:

- A noncluster table indexed on the primary key by using the `CREATE INDEX` statement
- A cluster table stored in an indexed cluster that has been created using the `CREATE CLUSTER` statement that maps the primary key for the table to the cluster key

You must specify a primary key for an index-organized table, because the primary key uniquely identifies a row. The primary key cannot be DEFERRABLE. Use the primary key instead of the rowid for directly accessing index-organized rows.

If an index-organized table is partitioned and contains LOB columns, then you should specify the *index_org_table_clause* first, then the *LOB_storage_clause*, and then the appropriate *table_partitioning_clauses*.

You cannot use the TO_LOB function to convert a LONG column to a LOB column in the subquery of a CREATE TABLE ... AS SELECT statement if you are creating an index-organized table. Instead, create the index-organized table without the LONG column, and then use the TO_LOB function in an INSERT ... AS SELECT statement.

The ROWID pseudocolumn of an index-organized table returns logical rowids instead of physical rowids. A column that you create with the data type ROWID cannot store the logical rowids of the IOT. The only data you can store in a column of type ROWID is rowids from heap-organized tables. If you want to store the logical rowids of an IOT, then create a column of type UROWID instead. A column of type UROWID can store both physical and logical rowids.

> **See Also:**
>
> "Index-Organized Table Example"

Restrictions on Index-Organized Tables

Index-organized tables are subject to the following restrictions:

- You cannot define a virtual (expression) column for an index-organized table.
- You cannot specify the *composite_range_partitions*, *composite_list_partitions*, or *composite_hash_partitions* clauses for an index-organized table.
- If the index-organized table is a nested table or varray, then you cannot specify *table_partitioning_clauses*.
- The collations of character data type columns belonging to the primary key of an index-organized table must be BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

PCTTHRESHOLD *integer*

Specify the percentage of space reserved in the index block for an index-organized table row. PCTTHRESHOLD must be large enough to hold the primary key. All trailing columns of a row, starting with the column that causes the specified threshold to be exceeded, are stored in the overflow segment. PCTTHRESHOLD must be a value from 1 to 50. If you do not specify PCTTHRESHOLD, then the default is 50.

Restriction on PCTTHRESHOLD

You cannot specify PCTTHRESHOLD for individual partitions of an index-organized table.

mapping_table_clauses

Specify MAPPING TABLE to instruct the database to create a mapping of local to physical ROWIDs and store them in a heap-organized table. This mapping is needed in order to create a bitmap index on the index-organized table. If the index-organized table is partitioned, then the

mapping table is also partitioned and its partitions have the same name and physical attributes as the base table partitions.

Oracle Database creates the mapping table or mapping table partition in the same tablespace as its parent index-organized table or partition. You cannot query, perform DML operations on, or modify the storage characteristics of the mapping table or its partitions.

prefix_compression

The *prefix_compression* clauses let you enable or disable prefix compression for index-organized tables.

- Specify COMPRESS to enable **prefix compression**, also known as key compression, for an index-organized table, which eliminates repeated occurrence of primary key column values in index-organized tables. Use *integer* to specify the prefix length, which is the number of prefix columns to compress.

  The valid range of prefix length values is from 1 to the number of primary key columns minus 1. The default prefix length is the number of primary key columns minus 1.

- Specify NOCOMPRESS to disable prefix compression in index-organized tables. This is the default.

Restriction on Prefix Compression of Index-organized Tables

At the partition level, you can specify COMPRESS, but you cannot specify the prefix length with *integer*.

iot_advanced_compression

Specify *iot_advanced_compression* to compress the indexes of index organized tables (IOTs) and table partitions in order to reduce the storage footprint of IOTs.

You can enable advanced low index compression for all IOTs on specific partitions of a table, and leave other partitions uncompressed.

index_org_overflow_clause

The *index_org_overflow_clause* lets you instruct the database that index-organized table data rows exceeding the specified threshold are placed in the data segment specified in this clause.

- When you create an index-organized table, Oracle Database evaluates the maximum size of each column to estimate the largest possible row. If an overflow segment is needed but you have not specified OVERFLOW, then the database raises an error and does not execute the CREATE TABLE statement. This checking function guarantees that subsequent DML operations on the index-organized table will not fail because an overflow segment is lacking.
- All physical attributes and storage characteristics you specify in this clause after the OVERFLOW keyword apply only to the overflow segment of the table. Physical attributes and storage characteristics for the index-organized table itself, default values for all its partitions, and values for individual partitions must be specified before this keyword.
- If the index-organized table contains one or more LOB columns, then the LOBs will be stored out-of-line unless you specify OVERFLOW, even if they would otherwise be small enough be to stored inline.
- If *table* is partitioned, then the database equipartitions the overflow data segments with the primary key index segments.

INCLUDING *column_name*

Specify a column at which to divide an index-organized table row into index and overflow portions. The primary key columns are always stored in the index. *column_name* can be either the last primary key column or any non primary key column. All non primary key columns that follow *column_name* are stored in the overflow data segment.

If an attempt to divide a row at *column_name* causes the size of the index portion of the row to exceed the specified or default PCTTHRESHOLD value, then the database breaks up the row based on the PCTTHRESHOLD value.

Restriction on the INCLUDING Clause

You cannot specify this clause for individual partitions of an index-organized table.

EXTERNAL PARTITION ATTRIBUTES
Use the **EXTERNAL PARTITION ATTRIBUTES** clause to specify table level external parameters in a hybrid partitioned table.

external_table_clause

Use the *external_table_clause* to create an external table, which allows you to process data that is stored outside the database from within the database without loading any of the data into the database.

Defining an external table only creates metadata in the data dictionary, pointing to data outside the database and providing seamless read only access to such data.

Because external tables have no data in the database, you define them with a small subset of the clauses normally available when creating tables.

In addition to supporting external data residing in operating file systems and Big Data sources and formats such as HDFS and Hive, Oracle supports external data residing in objects via the DBMS_CLOUD package.

You can work with data in object stores using the DBMS_CLOUD package or by manually defining external tables. Oracle strongly recommends using DBMS_CLOUD for the additional functionality that is fully compatible with Oracle autonomous database.

> **See Also:**
>
> - *DBMS_CLOUD*
> - *Managing External Tables*

- Within the *relational_properties* clause, you can specify only *column*, *datatype*, ENCRYPT, *inline_constraint*, and *out_of_line_constraint*. You can specify the ENCRYPT clause only when you specify the ORACLE_DATAPUMP access driver and the AS *subquery* clause to load data into the external table. Within the *inline_constraint* and *out_of_line_constraint* clauses, you can specify all subclauses except CHECK.
- Within the *physical_properties_clause*, you can specify only the organization of the table (ORGANIZATION EXTERNAL *external_table_clause*).
- Within the *table_properties* clause, you can specify the *parallel_clause*. The *parallel_clause* lets you parallelize subsequent queries on the external data and subsequent operations that populate the external table.

Starting with Oracle Database 12*c* Release 2 (12.2), you can create a **partitioned external table**. To do this, within the *table_properties* clause, you can specify the following subclauses of the *table_partitioning_clauses* :

  - *range_partitions* - specify this clause to create a range-partitioned or interval-partitioned external table
  - *list_partitions* - specify this clause to create a list-partitioned external table. Within this clause, you cannot specify the AUTOMATIC clause; an automatic list-partitioned table cannot be an external table.
  - *composite_range_partitions* - specify this clause to create a range-range, range-list, interval-range, or interval-list composite-partitioned external table
  - *composite_list_partitions* - specify this clause to create a list-range or list-list composite-partitioned external table. Within this clause, you cannot specify the AUTOMATIC clause; an automatic composite-partitioned table cannot be an external table.

- You can populate the external table at create time by using the AS *subquery* clause.

No other clauses are permitted in the same CREATE TABLE statement.

> **See Also:**
>
> - "External Table Example"
> - ALTER TABLE ... "PROJECT COLUMN Clause" for information on the effect of changing the default property of the column projection
> - *Oracle Database Data Warehousing Guide*, *Oracle Database Administrator's Guide*, and *Oracle Database Utilities* for information on the uses for external tables

Restrictions on External Tables

External tables are subject to the following restrictions:

- An external table cannot be a temporary table.
- You can specify only the following types of constraints on an external table: NOT NULL constraints, unique constraints, primary key constraints, and foreign key constraints. When you specify unique constraints, primary key constraints, or foreign key constraints, you must also specify RELY DISABLE. These constraints are declarative and are not enforced. They can increase query performance and reduce resource consumption because more optimizer transformations can be taken into account. In order for the optimizer to utilize these RELY DISABLE constraints, the QUERY_REWRITE_INTEGRITY initialization parameter must be set to either trusted or stale_tolerated.
- You cannot create an index on an external table.
- An external table cannot contain INVISIBLE columns.
- An external table cannot have object type, varray, or LONG columns. However, you can populate LOB columns of an external table with varray or LONG data from an internal database table.
- Only ORACLE_LOADER and ORACLE_DATAPUMP access types are permitted for external tables that can be populated into the inmemory column store.

TYPE

TYPE *access_driver_type* indicates the **access driver** of the external table. The access driver is the API that interprets the external data for the database. Oracle Database provides the following access drivers: ORACLE_LOADER, ORACLE_DATAPUMP, ORACLE_HDFS, and ORACLE_HIVE. If you do not specify TYPE, then the database uses ORACLE_LOADER as the default access driver. You must specify the ORACLE_DATAPUMP access driver if you specify the AS *subquery* clause to unload data from one Oracle Database and reload it into the same or a different Oracle Database.

Restrictions

ORACLE_HIVE column names should be limited to [A-ZA-Z0-9_]+ on partitioning external tables.

> **See Also:**
>
> *Oracle Database Utilities* for information about the ORACLE_LOADER, ORACLE_DATAPUMP, ORACLE_HDFS, and ORACLE_HIVE access drivers

DEFAULT DIRECTORY

DEFAULT DIRECTORY lets you specify a default directory object corresponding to a directory on the file system where the external data sources may reside. The default directory can also be used by the access driver to store auxiliary files such as error logs.

ACCESS PARAMETERS

The optional ACCESS PARAMETERS clause lets you assign values to the parameters of the specific access driver for this external table.

- The *opaque_format_spec* specifies all access parameters for the ORACLE_LOADER, ORACLE_DATAPUMP, ORACLE_HDFS, and ORACLE_HIVE access drivers. See *Oracle Database Utilities* for descriptions of the ORACLE_LOADER, ORACLE_DATAPUMP, ORACLE_HDFS, and ORACLE_HIVE access parameters.

  Field names specified in the *opaque_format_spec* must match columns in the table definition. Oracle Database ignores any field in the *opaque_format_spec* that is not matched by a column in the table definition.

- USING CLOB *subquery* lets you derive the parameters and their values through a subquery. The subquery cannot contain any set operators or an ORDER BY clause. It must return one row containing a single item of data type CLOB.

Whether you specify the parameters in an *opaque_format_spec* or derive them using a subquery, the database does not interpret anything in this clause. It is up to the access driver to interpret this information in the context of the external data.

For inline external tables and external modify query statements you must use *opaque_format_spec* within single quotes. For DDL statements you must use *opaque_format_spec* without single quotes.

LOCATION

The LOCATION clause lets you specify one or more external data sources. Usually the *location_specifier* is a file, but it need not be. Oracle Database does not interpret this clause. It is up to the access driver to interpret this information in the context of the external data.

You must specify the LOCATION clause as follows:

- When creating a nonpartitioned external table, you must specify the LOCATION clause at the table level in the *external_table_data_props* clause.
- When creating a partitioned external table, you must specify the LOCATION clause at the partition level in the *external_part_subpart_data_props* clause.
- When creating a composite-partitioned external table, you must specify the LOCATION clause at the subpartition level in the *external_part_subpart_data_props* clause.

REJECT LIMIT

The REJECT LIMIT clause lets you specify how many conversion errors can occur during a query of the external data before an Oracle Database error is returned and the query is aborted. The default value is 0.

CLUSTER Clause

The CLUSTER clause indicates that the table is to be part of *cluster*. The columns listed in this clause are the table columns that correspond to the cluster columns. Generally, the cluster columns of a table are the column or columns that make up its primary key or a portion of its primary key. Refer to CREATE CLUSTER for more information.

Specify one column from the table for each column in the cluster key. The columns are matched by position, not by name.

A cluster table uses the space allocation of the cluster. Therefore, do not use the PCTFREE, PCTUSED, or INITRANS parameters, the TABLESPACE clause, or the *storage_clause* with the CLUSTER clause.

Restrictions on Cluster Tables

Cluster tables are subject to the following restrictions:

- Object tables and tables containing LOB columns or columns of the Any* Oracle-supplied types cannot be part of a cluster.
- You cannot specify the *parallel_clause* or CACHE or NOCACHE for a table that is part of a cluster.
- You cannot specify CLUSTER with either ROWDEPENDENCIES or NOROWDEPENDENCIES unless the cluster has been created with the same ROWDEPENDENCIES or NOROWDEPENDENCIES setting.
- A cluster table cannot contain INVISIBLE columns.

table_properties

The *table_properties* further define the characteristics of the table.

column_properties

Use the *column_properties* clauses to specify the storage attributes of a column.

object_type_col_properties

The *object_type_col_properties* determine storage characteristics of an object column or attribute or of an element of a collection column or attribute.

column

For *column*, specify an object column or attribute.

substitutable_column_clause

The *substitutable_column_clause* indicates whether object columns or attributes in the same hierarchy are substitutable for each other. You can specify that a column is of a particular type, or whether it can contain instances of its subtypes, or both.

- If you specify ELEMENT, then you constrain the element type of a collection column or attribute to a subtype of its declared type.
- The IS OF [TYPE] (ONLY *type*) clause constrains the type of the object column to a subtype of its declared type.
- NOT SUBSTITUTABLE AT ALL LEVELS indicates that the object column cannot hold instances corresponding to any of its subtypes. Also, substitution is disabled for any embedded object attributes and elements of embedded nested tables and varrays. The default is SUBSTITUTABLE AT ALL LEVELS.

Restrictions on the *substitutable_column_clause*

This clause is subject to the following restrictions:

- You cannot specify this clause for an attribute of an object column. However, you can specify this clause for a object type column of a relational table and for an object column of an object table if the substitutability of the object table itself has not been set.
- For a collection type column, the only part of this clause you can specify is [NOT] SUBSTITUTABLE AT ALL LEVELS.

LOB_storage_clause

The *LOB_storage_clause* lets you specify the storage attributes of LOB data segments. You must specify at least one clause after the STORE AS keywords. If you specify more than one clause, then you must specify them in the order shown in the syntax diagram, from top to bottom.

For a nonpartitioned table, this clause specifies the storage attributes of LOB data segments of the table.

For a partitioned table, Oracle Database implements this clause depending on where it is specified:

- For a partitioned table specified at the table level—when specified in the *physical_properties* clause along with one of the partitioning clauses—this clause specifies the default storage attributes for LOB data segments associated with each partition or subpartition. These storage attributes apply to all partitions or subpartitions unless overridden by a *LOB_storage_clause* at the partition or subpartition level.
- For an individual partition of a partitioned table—when specified as part of a *table_partition_description*—this clause specifies the storage attributes of the data segments of the partition or the default storage attributes of any subpartitions of the partition. A partition-level *LOB_storage_clause* overrides a table-level *LOB_storage_clause*.
- For an individual subpartition of a partitioned table—when specified as part of *subpartition_by_hash* or *subpartition_by_list*—this clause specifies the storage attributes of the data segments of the subpartition. A subpartition-level *LOB_storage_clause* overrides both partition-level and table-level *LOB_storage_clauses*.

Restriction on the *LOB_storage_clause*:

Only the TABLESPACE clause is allowed when specifying the *LOB_storage_clause* in a subpartition.

> **See Also:**
>
> - *Oracle Database SecureFiles and Large Objects Developer's Guide* for detailed information about LOBs, including guidelines for creating gigabyte LOBs
> - "Creating a Table: LOB Column Example"

LOB_item

Specify the LOB column name or LOB object attribute for which you are explicitly defining tablespace and storage characteristics that are different from those of the table. Oracle Database automatically creates a system-managed index for each *LOB_item* you create.

SECUREFILE | BASICFILE

Use this clause to specify the type of LOB storage, either high-performance LOB (SecureFiles), or the traditional LOB (BasicFiles).

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information about SecureFiles LOBs

> **Note:**
>
> You cannot convert a LOB from one type of storage to the other. Instead you must migrate to SecureFiles or BasicFiles by using online redefinition or partition exchange.

LOB_segname

Specify the name of the LOB data segment. You cannot use *LOB_segname* if you specify more than one *LOB_item*.

LOB_storage_parameters

The *LOB_storage_parameters* clause lets you specify various elements of LOB storage.

TABLESPACE Clause

Use this clause to specify the tablespace in which LOB data is to be stored.

TABLESPACE SET Clause

This clause is valid only when creating a sharded table by specifying the `SHARDED` keyword of `CREATE TABLE`. Use this clause to specify the tablespace set in which LOB data is to be stored.

storage_clause

Use the *storage_clause* to specify various aspects of LOB segment storage. Of particular interest in the context of LOB storage is the `MAXSIZE` clause of the *storage_clause*, which can

be used in combination with the *LOB_retention_clause* of *LOB_parameters*. Refer to *storage_clause* for more information.

LOB_parameters

Several of the *LOB_parameters* are no longer needed if you are using SecureFiles for LOB storage. The PCTVERSION and FREEPOOLS parameters are valid and useful only if you are using BasicFiles LOB storage.

ENABLE STORAGE IN ROW

If you enable storage in row, then the LOB value is stored in the row (inline) if its length is less than approximately 4000 bytes minus system control information. This is the default.

Restriction on Enabling Storage in Row

For an index-organized table, you cannot specify this parameter unless you have specified an OVERFLOW segment in the *index_org_table_clause*.

DISABLE STORAGE IN ROW

If you disable storage in row, then the LOB value is stored outside of the row out of line regardless of the length of the LOB value.

The LOB locator is always stored inline regardless of where the LOB value is stored. You cannot change the value of STORAGE IN ROW once it is set except by moving the table. See the *move_table_clause* in the ALTER TABLE documentation for more information.

CHUNK *integer*

Specify the number of bytes to be allocated for LOB manipulation. If *integer* is not a multiple of the database block size, then the database rounds up in bytes to the next multiple. For example, if the database block size is 2048 and *integer* is 2050, then the database allocates 4096 bytes (2 blocks). The maximum value is 32768 (32K), which is the largest Oracle Database block size allowed. The default CHUNK size is one Oracle Database block.

The value of CHUNK must be less than or equal to the value of NEXT, either the default value or that specified in the *storage_clause*. If CHUNK exceeds the value of NEXT, then the database returns an error. You cannot change the value of CHUNK once it is set.

PCTVERSION *integer*

Specify the maximum percentage of overall LOB storage space used for maintaining old versions of the LOB. If the database is running in manual undo mode, then the default value is 10, meaning that older versions of the LOB data are not overwritten until they consume 10% of the overall LOB storage space.

You can specify the PCTVERSION parameter whether the database is running in manual or automatic undo mode. PCTVERSION is the default in manual undo mode. RETENTION is the default in automatic undo mode. You cannot specify both PCTVERSION and RETENTION.

This clause is not valid if you have specified SECUREFILE. If you specify both SECUREFILE and PCTVERSION, then the database silently ignores the PCTVERSION parameter.

LOB_retention_clause

Use this clause to specify whether you want the LOB segment retained for flashback purposes, consistent-read purposes, both, or neither.

You can specify the RETENTION parameter only if the database is running in automatic undo mode. Oracle Database uses the value of the UNDO_RETENTION initialization parameter to

determine the amount of committed undo data to retain in the database. In automatic undo mode, RETENTION is the default value unless you specify PCTVERSION. You cannot specify both PCTVERSION and RETENTION.

You can specify the optional settings after RETENTION only if you are using SecureFiles. The SECUREFILE parameter of the *LOB_storage_clause* indicates that the database will use SecureFiles to manage storage dynamically, taking into account factors such as the undo mode of the database.

- Specify MAX to signify that the undo should be retained until the LOB segment has reached MAXSIZE. If you specify MAX, then you must also specify the MAXSIZE clause in the *storage_clause*.
- Specify MIN if the database is in flashback mode to limit the undo retention **duration** for the specific LOB segment to *n* seconds.
- Specify AUTO if you want to retain undo sufficient for consistent read purposes only.
- Specify NONE if no undo is required for either consistent read or flashback purposes.

If you do not specify the RETENTION parameter, or you specify RETENTION with no optional settings, then RETENTION is set to DEFAULT, which is functionally equivalent to AUTO.

> **See Also:**
>
> - To set the UNDO_RETENTION initialization parameter, see Setting the Minimum Undo Retention Period
> - CREATE TABLE clause *LOB_storage_parameters* for more information on simplified LOB storage using SecureFiles
> - *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information on using SecureFiles
> - *flashback_mode_clause* of ALTER DATABASE for information on putting a database in flashback mode
> - "Creating an Undo Tablespace: Example"

FREEPOOLS *integer*

Specify the number of groups of free lists for the LOB segment. Normally *integer* will be the number of instances in an Oracle Real Application Clusters environment or 1 for a single-instance database.

You can specify this parameter only if the database is running in automatic undo mode. In this mode, FREEPOOLS is the default unless you specify the FREELIST GROUPS parameter of the *storage_clause*. If you specify neither FREEPOOLS nor FREELIST GROUPS, then the database uses a default of FREEPOOLS 1 if the database is in automatic undo management mode and a default of FREELIST GROUPS 1 if the database is in manual undo management mode.

This clause is not valid if you have specified SECUREFILE. If you specify both SECUREFILE and FREEPOOLS, then the database silently ignores the FREEPOOLS parameter.

Restriction on FREEPOOLS

You cannot specify both FREEPOOLS and the FREELIST GROUPS parameter of the *storage_clause*.

LOB_deduplicate_clause

This clause is valid only for SecureFiles LOBs. Use the *LOB_deduplicate_clause* to enable or disable LOB deduplication, which is the elimination of duplicate LOB data.

The DEDUPLICATE keyword instructs the database to eliminate duplicate copies of LOBs. Using a secure hash index to detect duplication, the database coalesces LOBs with identical content into a single copy, reducing storage consumption and simplifying storage management.

If you omit this clause, then LOB deduplication is disabled by default.

This clause implements LOB deduplication for the entire LOB segment. To enable or disable deduplication for an individual LOB, use the DBMS_LOB.SETOPTIONS procedure.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information about LOB deduplication and *Oracle Database PL/SQL Packages and Types Reference* for information about about the DBMS_LOB package

LOB_compression_clause

This clause is valid only for SecureFiles LOBs, not for BasicFiles LOBs. Use the *LOB_compression_clause* to instruct the database to enable or disable server-side LOB compression. Random read/write access is possible on server-side compressed LOB segments. LOB compression is independent from table compression or index compression. If you omit this clause, then the default is NOCOMPRESS.

You can specify HIGH, MEDIUM, or LOW to vary the degree of compression. The HIGH degree of compression incurs higher latency than MEDIUM but provides better compression. The LOW degree results in significantly higher decompression and compression speeds, at the cost of slightly lower compression ratio than either HIGH or MEDIUM. If you omit this optional parameter, then the default is MEDIUM.

This clause implements server-side LOB compression for the entire LOB segment. To enable or disable compression on an individual LOB, use the DBMS_LOB.SETOPTIONS procedure.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information on server-side LOB storage and *Oracle Database PL/SQL Packages and Types Reference* for information about client-side LOB compression using the UTL_COMPRESS supplied package and for information about the DBMS_LOB package

ENCRYPT | DECRYPT

These clauses are valid only for LOBs that are using SecureFiles for LOB storage. Specify ENCRYPT to encrypt all LOBs in the column. Specify DECRYPT to keep the LOB in cleartext. If you omit this clause, then DECRYPT is the default.

Refer to *encryption_spec* for general information on that clause. When applied to a LOB column, *encryption_spec* is specific to the individual LOB column, so the encryption algorithm can differ from that of other LOB columns and other non-LOB columns. Use the

encryption_spec as part of the *column_definition* to encrypt the entire LOB column. Use the *encryption_spec* as part of the *LOB_storage_clause* in the *table_partition_description* to encrypt a LOB partition.

Restriction on *encryption_spec* for LOBs

You cannot specify the SALT or NO SALT clauses of *encryption_spec* for LOB encryption.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information on LOB encryption and *Oracle Database PL/SQL Packages and Types Reference* for information the DBMS_LOB package

CACHE | NOCACHE | CACHE READS

Refer to CACHE | NOCACHE | CACHE READS for information on these clauses.

LOB_partition_storage

The *LOB_partition_storage* clause lets you specify a separate *LOB_storage_clause* or *varray_col_properties* clause for each partition. You must specify the partitions in the order of partition position. You can find the order of the partitions by querying the PARTITION_NAME and PARTITION_POSITION columns of the USER_IND_PARTITIONS view.

If you do not specify a *LOB_storage_clause* or *varray_col_properties* clause for a particular partition, then the storage characteristics are those specified for the LOB item at the table level. If you also did not specify any storage characteristics for the LOB item at the table level, then Oracle Database stores the LOB data partition in the same tablespace as the table partition to which it corresponds.

Restrictions on *LOB_partition_storage*

LOB_partition_storage is subject to the following restrictions:

- In the *LOB_parameters* of the *LOB_storage_clause*, you cannot specify *encryption_spec*, because it is invalid to specify an encryption algorithm for partitions and subpartitions.
- You can only specify the TABLESPACE clause for hash partitions and all types of subpartitions.

varray_col_properties

The *varray_col_properties* let you specify separate storage characteristics for the LOB in which a varray will be stored. If *varray_item* is a multilevel collection, then the database stores all collection items nested within *varray_item* in the same LOB in which *varray_item* is stored.

- For a nonpartitioned table—when specified in the *physical_properties* clause without any of the partitioning clauses—this clause specifies the storage attributes of the LOB data segments of the varray.
- For a partitioned table specified at the table level—when specified in the *physical_properties* clause along with one of the partitioning clauses—this clause specifies the default storage attributes for the varray LOB data segments associated with each partition (or its subpartitions, if any).

- For an individual partition of a partitioned table—when specified as part of a *table_partition_description*—this clause specifies the storage attributes of the varray LOB data segments of that partition or the default storage attributes of the varray LOB data segments of any subpartitions of this partition. A partition-level *varray_col_properties* overrides a table-level *varray_col_properties*.
- For an individual subpartition of a partitioned table—when specified as part of *subpartition_by_hash* or *subpartition_by_list*—this clause specifies the storage attributes of the varray data segments of this subpartition. A subpartition-level *varray_col_properties* overrides both partition-level and table-level *varray_col_properties*.

STORE AS [SECUREFILE | BASICFILE] LOB Clause

If you specify `STORE AS LOB`, then:

- If the maximum varray size is less than approximately 4000 bytes, then the database stores the varray as an inline LOB unless you have disabled storage in row.
- If the maximum varray size is greater than approximately 4000 bytes or if you have disabled storage in row, then the database stores in the varray as an out-of-line LOB.

If you do not specify `STORE AS LOB`, then storage is based on the maximum possible size of the varray rather than on the actual size of a varray column. The maximum size of the varray is the number of elements times the element size, plus a small amount for system control information. If you omit this clause, then:

- If the maximum size of the varray is less than approximately 4000 bytes, then the database does not store the varray as a LOB, but as inline data.
- If the maximum size is greater than approximately 4000 bytes, then the database always stores the varray as a LOB.
  - If the actual size is less than approximately 4000 bytes, then it is stored as an inline LOB
  - If the actual size is greater than approximately 4000 bytes, then it is stored as an out-of-line LOB, as is true for other LOB columns.

substitutable_column_clause

The *substitutable_column_clause* has the same behavior as described for object_type_col_properties.

> **See Also:**
>
> "Substitutable Table and Column Examples"

Restriction on Varray Column Properties

You cannot specify this clause on an interval partitioned table.

nested_table_col_properties

The *nested_table_col_properties* let you specify separate storage characteristics for a nested table, which in turn enables you to define the nested table as an index-organized table. Unless you explicitly specify otherwise in this clause:

- For a nonpartitioned table, the storage table is created in the same schema and the same tablespace as the parent table.
- For a partitioned table, the storage table is created in the default tablespace of the schema. By default, nested tables are equipartitioned with the partitioned base table.
- In either case, the storage table uses default storage characteristics, and stores the nested table values of the column for which it was created.

You must include this clause when creating a table with columns or column attributes whose type is a nested table. Clauses within *nested_table_col_properties* that function the same way they function for the parent table are not repeated here.

nested_item

Specify the name of a column, or of a top-level attribute of the object type of the tables, whose type is a nested table.

COLUMN_VALUE

If the nested table is a multilevel collection, then the inner nested table or varray may not have a name. In this case, specify COLUMN_VALUE in place of the *nested_item* name.

> **See Also:**
>
> "Creating a Table: Multilevel Collection Example" for examples using *nested_item* and COLUMN_VALUE

LOCAL | GLOBAL

Specify LOCAL to equipartition the nested table with the base table. This is the default. Oracle Database automatically creates a local partitioned index for the partitioned nested table.

Specify GLOBAL to indicate that the nested table is a nonpartitioned nested table of a partitioned base table.

storage_table

Specify the name of the table where the rows of *nested_item* reside.

You cannot query or perform DML statements on *storage_table* directly, but you can modify its storage characteristics by specifying its name in an ALTER TABLE statement.

> **See Also:**
>
> ALTER TABLE for information about modifying nested table column storage characteristics

RETURN [AS]

Specify what Oracle Database returns as the result of a query.

- VALUE returns a copy of the nested table itself.
- LOCATOR returns a collection locator to the copy of the nested table.

The locator is scoped to the session and cannot be used across sessions. Unlike a LOB locator, the collection locator cannot be used to modify the collection instance.

If you do not specify the *segment_attributes_clause* or the *LOB_storage_clause*, then the nested table is heap organized and is created with default storage characteristics.

Restrictions on Nested Table Column Properties

Nested table column properties are subject to the following restrictions:

- You cannot specify this clause for a temporary table.
- You cannot specify this clause on an interval partitioned table.
- You cannot specify the *oid_clause*.
- At create time, you cannot use *object_properties* to specify an *out_of_line_ref_constraint*, *inline_ref_constraint*, or foreign key constraint for the attributes of a nested table.

> **See Also:**
>
> - ALTER TABLE for information about modifying nested table column storage characteristics
> - "Nested Table Example" and "Creating a Table: Multilevel Collection Example"

XMLType_column_properties

The *XMLType_column_properties* let you specify storage attributes for an `XMLTYPE` column.

XMLType_storage

`XMLType` tables and columns data can be stored as transportable binary XML, binary XML, or a set of objects in object-relational storage.

- Specify `TRANSPORTABLE BINARY XML` to store XML data in a transportable format that is scalable and distributed. See Create Tables and Columns as Transportable Binary XML for examples.
  - `TRANSPORTABLE BINARY XML` can only be stored in `SECUREFILE`.
  - Any LOB parameters you specify are applied to the underlying BLOB column created for storing the transportable binary XML encoded value. .
  - You can not specify the *XMLSchema_spec* clause for `TRANSPORTABLE BINARY XML`.
- Specify `BINARY XML` to store the XML data in compact binary XML format.

  Any LOB parameters you specify are applied to the underlying `BLOB` column created for storing the binary XML encoded value.

  In earlier releases, binary XML data is stored by default in a BasicFiles LOB. Beginning with Oracle Database 11*g* Release 2 (11.2.0.2), if the `COMPATIBLE` initialization parameter is 11.2 or higher and you do not specify `BASICFILE` or `SECUREFILE`, then binary XML data is stored in a SecureFiles LOB whenever possible. If SecureFiles LOB storage is not possible then the binary XML data is stored in a BasicFiles LOB. This can occur if either of the following is true:

  - The tablespace for the XMLType table does not use automatic segment space management.
  - A setting in file init.ora prevents SecureFiles LOB storage. For example, see parameter DB_SECUREFILE in *Oracle Database Reference*.

- Specify CLOB if you want the database to store the XMLType data in a CLOB column. Storing data in a CLOB column preserves the original content and enhances retrieval time.

  If you specify LOB storage, then you can specify either LOB parameters or the *XMLSchema_spec* clause, but not both. Specify the *XMLSchema_spec* clause if you want to restrict the table or column to particular schema-based XML instances.

  If you do not specify BASICFILE or SECUREFILE with this clause, then the CLOB column is stored in a BasicFiles LOB.

  > **Note:**
  >
  > Oracle recommends against storing XMLType data in a CLOB column. CLOB storage of XMLType is deprecated. Use binary XML storage of XMLType instead.

- Specify OBJECT RELATIONAL if you want the database to store the XMLType data in object-relational columns. Storing data objects relationally lets you define indexes on the relational columns and enhances query performance.

  If you specify object-relational storage, then you must also specify the *XMLSchema_spec* clause.

  Use the ALL VARRAYS AS clause if you want the database to store all varrays in an XMLType column.

In earlier releases, XMLType data is stored in a CLOB column in a BasicFiles LOB by default. Beginning with Oracle Database 11*g* Release 2 (11.2.0.2), if the COMPATIBLE initialization parameter is 11.2 or higher and you do not specify the *XMLType_storage* clause, then XMLType data is stored in a binary XML column in a SecureFiles LOB. If SecureFiles LOB storage is not possible, then it is stored in a binary XML column in a BasicFiles LOB.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information on SecureFiles LOBs

XMLSchema_spec

Refer to the XMLSchema_spec for the full semantics of this clause.

> **See Also:**
>
> - *LOB_storage_clause* for information on the *LOB_segname* and *LOB_parameters* clauses
> - "XMLType Column Examples" for examples of XMLType columns in object-relational tables and "Using XML in SQL Statements " for an example of creating an XMLSchema
> - *Oracle XML DB Developer's Guide* for more information on XMLType columns and tables and on creating XMLSchemas
> - *Oracle Database PL/SQL Packages and Types Reference* for information on the DBMS_XMLSCHEMA package

XMLType_virtual_columns

This clause is valid only for XMLType tables with binary XML storage, which you designate in the *XMLType_storage* clause. Specify the VIRTUAL COLUMNS clause to define virtual (expression) columns, which can be used as in a function-based index or in the definition of a constraint. You cannot define a constraint on such a virtual (expression) column during creation of the table, but you can use a subsequent ALTER TABLE statement to add a constraint to the column.

> **See Also:**
>
> *Oracle XML DB Developer's Guide* for examples of how to use this clause in an XML environment

json_storage_clause

With support for JSON data type you can define a column of JSON data type using the *JSON_storage_clause*.

You can specify the JSON type modifier when you specify a JSON type column definition as follows:

Create a Table with a JSON Type Column: Example

This example creates table j_purchaseorder with JSON data type column po_document. Oracle recommends that you store JSON data as JSON type.

```
CREATE TABLE j_purchaseorder
        (id VARCHAR2 (32) NOT NULL PRIMARY KEY,
         date_loaded TIMESTAMP (6) WITH TIME ZONE,
         po_document JSON );
```

> **See Also:**
>
> For more information on creating a JSON column see *Creating a Table with a JSON Column of the JSON developer's Guide.*

read_only_clause

This clause lets you specify whether to create a table, partition, or subpartition in read-only or read/write mode.

- Use `READ ONLY` to specify read-only mode. When an object is in read-only mode, you cannot issue any DML statements that affect the object or any `SELECT ... FOR UPDATE ...` statements on the object. You can issue DDL statements as long as they do not modify any table data. See *Oracle Database Administrator's Guide* for the complete list of operations that are allowed and disallowed on read-only objects.
- Use `READ WRITE` to specify read/write mode. This is the default.

When you specify this clause for a partitioned table, you specify the default read-only or read/write mode for the table. This mode is assigned to all partitions in the table at creation time, as well as any partitions that are subsequently added to the table, unless you override this behavior by specifying the mode at the partition level.

When you specify this clause for a composite-partitioned table, you specify the default read-only or read/write mode for all partitions in the table. You can override this behavior by specifying this clause for a particular partition. The default mode of a partition is assigned to all subpartitions in the partition at creation time, as well as any subpartitions that are subsequently added to the partition, unless you override this behavior by specifying the mode at the subpartition level.

indexing_clause

The *`indexing_clause`* is valid only for partitioned tables. Use this clause to set the **indexing property** for a table, table partition, or table subpartition.

- Specify `INDEXING ON` to set the indexing property to `ON`. This is the default.
- Specify `INDEXING OFF` to set the indexing property to `OFF`.

The indexing property determines whether table partitions and subpartitions are included in partial indexes on the table.

- For simple partitioned tables, partitions with an indexing property of `ON` are included in partial indexes on the table. Partitions with an indexing property of `OFF` are excluded.
- For composite-partitioned tables, subpartitions with an indexing property of `ON` are included in partial indexes on the table. Subpartitions with an indexing property of `OFF` are excluded.

You can specify the *`indexing_clause`* at the table, partition, or subpartition level. When you specify the *`indexing_clause`* at the table level, in the *`table_properties`* clause, you set the default indexing property for the table. Interval partitions, which are automatically created by the database, always inherit the default indexing property for the table. Other types of partitions and subpartitions inherit the default indexing property as follows:

- For simple partitioned tables, partitions inherit the default indexing property for the table. You can override this behavior by specifying the *`indexing_clause`* for an individual partition:
  - For a range partition, in the *`table_partition_description`* of the *`range_partitions`* clause
  - For a hash partition, in the *`individual_hash_partitions`* clause of the *`hash_partitions`* clause
  - For a list partition, in the *`table_partition_description`* of the *`list_partitions`* clause

  - For a reference partition, in the *table_partition_description* of the *reference_partition_desc* clause of the *reference_partitioning* clause
  - For a system partition, in the *table_partition_description* of the *reference_partition_desc* clause of the *system_partitioning* clause

- For composite-partitioned tables, subpartitions inherit the default indexing property for the table. You can override this behavior by specifying the *indexing_clause* for an individual partition or subpartition.

  If you specify the *indexing_clause* for a partition, then its subpartitions inherit the indexing property of the partition:

  - For composite range partitions, in the *table_partition_description* of the *composite_range_partitions* clause
  - For composite list partitions, in the *table_partition_description* of the *composite_list_partitions* clause
  - For composite hash partitions, in the *individual_hash_partitions* clause of the *composite_hash_partitions* clause

  You can set the indexing property of a subpartition by specifying the *indexing_clause* for the subpartition:

  - For range subpartitions, in the *range_subpartition_desc* clause of the *composite_range_partitions* clause
  - For list subpartitions, in the *list_subpartition_desc* clause of the *composite_list_partitions* clause
  - For hash subpartitions, in the *individual_hash_subparts* clause of the *composite_hash_partitions* clause

> **See Also:**
>
> *Oracle Database Reference* for information on viewing the indexing property of a table, table partition, or table subpartition.
>
> - To view the default indexing property of a table, query the `DEF_INDEXING` column of the `*_PART_TABLES` views.
> - To view the indexing property of a table partition, query the `INDEXING` column of the `*_TAB_PARTITIONS` views.
> - To view the indexing property of a table subpartition, query the `INDEXING` column of the `*_TAB_SUBPARTITIONS` views.

Restrictions on the *indexing_clause*

The *indexing_clause* is subject to the following restrictions:

- You cannot specify the *indexing_clause* for nonpartitioned tables.
- You cannot specify the *indexing_clause* for index-organized tables.

> **See Also:**
>
> The *partial_index_clause* of `CREATE INDEX` for more information on partial indexes

table_partitioning_clauses

Use the *table_partitioning_clauses* to create a partitioned table.

Notes on Partitioning in General

The following notes pertain to all types of partitioning:

- You can specify up to a total of 1024K-1 partitions and subpartitions.
- You can create a partitioned table with just one partition. A table with one partition is different from a nonpartitioned table. For example, you cannot add a partition to a nonpartitioned table.
- You can specify a name for every table and LOB partition and for every table and LOB subpartition, but you need not do so. If you specify a name, then it must conform to the rules for naming schema objects and their parts as described in Database Object Naming Rules . If you omit the name, then the database generates names as follows:
  - If you omit a partition name, then the database generates a name of the form `SYS_Pn`. System-generated names for LOB data and LOB index partitions take the form `SYS_LOB_Pn` and `SYS_IL_Pn`, respectively.
  - If you specify a subpartition name in *subpartition_template*, then for each subpartition created with that template, the database generates a name by concatenating the partition name with the template subpartition name. For LOB subpartitions, the generated LOB subpartition name is a concatenation of the partition name and the template LOB segment name. If the `COMPATIBLE` initialization parameter is set to `12.2` or higher, then the maximum length of the concatenation is 128 bytes; otherwise, the maximum length is 30 bytes. If the concatenation exceeds the maximum length, then the database returns an error and the statement fails.
  - If you omit a subpartition name when specifying an individual subpartition, and you have not specified *subpartition_template*, then the database generates a name of the form `SYS_SUBPn`. The corresponding system-generated names for LOB data and index subpartitions are `SYS_LOB_SUBPn` and `SYS_IL_SUBPn`, respectively.
- Tablespace storage can be specified at various levels in the `CREATE TABLE` statement for both table segments and LOB segments. The number of tablespaces does not have to equal the number of partitions or subpartitions. If the number of partitions or subpartitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

  The database evaluates tablespace storage in the following order of descending priority:
  - Tablespace storage specified at the individual table subpartition or LOB subpartition level has the highest priority, followed by storage specified for the partition or LOB in the *subpartition_template*.
  - Tablespace storage specified at the individual table partition or LOB partition level. Storage parameters specified here take precedence over the *subpartition_template*.
  - Tablespace storage specified for the table
  - Default tablespace storage specified for the user

- By default, nested tables are equipartitioned with the partitioned base table.

Restrictions on Partitioning in General

All partitioning is subject to the following restrictions:

- You cannot partition a table that is part of a cluster.
- You cannot partition a nested table or varray that is defined as an index-organized table.
- You cannot partition a table containing any `LONG` or `LONG RAW` columns.

Restrictions on Hybrid Partitioned Tables

- Restrictions that apply to external tables also apply to hybrid partitioned tables unless explicitly noted. Only DML operations are supported on internal partitions of a hybrid partitioned table (external partitions are treated as read-only partitions).
- Only single level `LIST`, `RANGE`, interval and autolist partitioning are supported.
- The following DDLs are supported: `ADD PARTITION`, `ADD SUBPARTITION`, `DROP PARTITION`, `DROP SUBPARTITION`, `EXCHANGE PARTITION`, `EXCHANGE SUBPARTITION` on internal and external partitions and subpartitions. Partitions and subpartitions can also be renamed.
- The DDLs `MOVE`, `SPLIT` and `MERGE` are supported on internal partition and subpartitions only.
- Existing DMLs are supported on internal partitions only. External partitions are treated as read-only. All triggers are supported.
- Table level non-enforced constraints in mandatory `RELY DISABLE` mode are supported. The only supported enforced constraint is `NOT NULL` constraint.
- Unique indexes and global unique indexes are not supported. Only non-unique partial indexes are supported on internal partitions. External partitions are not indexable.
- Only single level list partitioning is supported for HIVE.
- Attribute clustering (`CLUSTERING` clause) is not allowed.
- In-memory defined on the table level only has an effect on internal partitions of the hybrid partitioned table.
- No column default value is allowed.
- Invisible columns are not allowed.
- The `CELLMEMORY` clause is not allowed.
- `SPLIT`, `MERGE`, and `MOVE` maintenance operations are not allowed on external partitions.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to *Oracle Database VLDB and Partitioning Guide* for a discussion of these restrictions.

> **See Also:**
>
> "Partitioning Examples"

range_partitions

Use the *range_partitions* clause to partition the table on ranges of values from the column list. For an index-organized table, the column list must be a subset of the primary key columns of the table.

Restrictions on Range Partitioning

Range partitioning is subject to the restrictions listed in "Restrictions on Partitioning in General". The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
- Partitioning key columns must be of type `CHAR`, `NCHAR`, `VARCHAR2`, `NVARCHAR2`, `VARCHAR`, `NUMBER`, `FLOAT`, `DATE`, `TIMESTAMP`, `TIMESTAMP WITH LOCAL TIMEZONE`, or `RAW`.
- Each range partitioning key column with a character data type that belongs to an `XMLType` table or a table with an `XMLType` column, or that is used as a sharding key column must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`. For all these collations, partition bounds are checked using the collation `BINARY`.
- You cannot specify NULL in the `VALUES` clause.

column

Specify an ordered list of columns used to determine into which partition a row belongs. These columns are the **partitioning key**. You can specify virtual (expression) columns and `INVISIBLE` columns as partitioning key columns.

INTERVAL Clause

Use this clause to establish **interval partitioning** for the table. Interval partitions are partitions based on a numeric range or datetime interval. They extend range partitioning by instructing the database to create partitions of the specified range or interval automatically when data inserted into the table exceeds all of the range partitions. For each automatically created partition, the database generates a name of the form `SYS_Pn`. The database guarantees that automatically generated partition names are unique and do not violate namespace rules.

- For *`expr`*, specify a valid number or interval expression.
- The optional `STORE IN` clause lets you specify one or more tablespaces into which the database will store interval partition data.
- You must also specify at least one range partition using the `PARTITION` clause of *`range_partitions`*. The range partition key value determines the high value of the range partitions, which is called the **transition point**, and the database creates interval partitions for data beyond that transition point.

Restrictions on Interval Partitioning

The `INTERVAL` clause is subject to the restrictions listed in "Restrictions on Partitioning in General" and "Restrictions on Range Partitioning". The following additional restrictions apply:

- You can specify only one partitioning key column, and it must be of type `NUMBER`, `DATE`, `FLOAT`, `TIMESTAMP`, or `TIMESTAMP WITH LOCAL TIME ZONE`.
- This clause is not supported for index-organized tables.
- This clause is not supported for tables containing varray columns.
- You cannot create an interval-partitioned table with equipartitioned nested tables. If you create an interval-partitioned table using nested tables or XML object-relational data types, then the nested tables will be created as nonpartitioned tables.
- This clause is supported for tables containing `XMLType` columns only if the XML data is stored as binary XML.
- Interval partitioning is not supported at the subpartition level.

- Serializable transactions do not work with interval partitioning. Trying to insert data into a partition of an interval partitioned table that does not yet have a segment causes an error.
- In the `VALUES` clause:
  - You cannot specify `MAXVALUE` (an infinite upper bound), because doing so would defeat the purpose of the automatic addition of partitions as needed.
  - You cannot specify `NULL` values for the partitioning key column.

> **See Also:**
>
> *Oracle Database VLDB and Partitioning Guide* for more information on interval partitioning

PARTITION *partition*

If you specify a partition name, then the name *partition* must conform to the rules for naming schema objects and their part as described in "Database Object Naming Rules ". If you omit *partition*, then the database generates a name as described in "Notes on Partitioning in General".

range_values_clause

Specify the noninclusive upper bound for the current partition. The value list is an ordered list of literal values corresponding to the column list in the *range_partitions* clause. You can substitute the keyword `MAXVALUE` for any literal in the value list. `MAXVALUE` specifies a maximum value that will always sort higher than any other value, including null.

Specifying a value other than `MAXVALUE` for the highest partition bound imposes an implicit integrity constraint on the table.

> **Note:**
>
> If *table* is partitioned on a `DATE` column, and if the date format does not specify the first two digits of the year, then you must use the `TO_DATE` function with the `YYYY` 4-character format mask for the year. The `RRRR` format mask is not supported in this clause. The date format is determined implicitly by `NLS_TERRITORY` or explicitly by `NLS_DATE_FORMAT`. Refer to *Oracle Database Globalization Support Guide* for more information on these initialization parameters.

> **See Also:**
>
> *Oracle Database Concepts* for more information about partition bounds and "Range Partitioning Example"

table_partition_description

Use the *table_partition_description* to define the physical and storage characteristics of the table.

The clauses *deferred_segment_creation*, *segment_attributes_clause*, *table_compression*, *inmemory_clause*, and *ilm_clause* have the same function as described for the *physical_properties* of the table as a whole.

Use the *indexing_clause* to set the indexing property for a range, list, system, or reference table partition. Refer to the *indexing_clause* for more information.

The *prefix_compression* clause and OVERFLOW clause, have the same function as described for the *index_org_table_clause*.

LOB_storage_clause

The *LOB_storage_clause* lets you specify LOB storage characteristics for one or more LOB items in this partition or in any range or list subpartitions of this partition. If you do not specify the *LOB_storage_clause* for a LOB item, then the database generates a name for each LOB data partition as described in "Notes on Partitioning in General".

varray_col_properties

The *varray_col_properties* let you specify storage characteristics for one or more varray items in this partition or in any range or list subpartitions of this partition.

nested_table_col_properties

The *nested_table_col_properties* let you specify storage characteristics for one or more nested table storage table items in this partition or in any range or list subpartitions of this partition. Storage characteristics specified in this clause override any storage attributes specified at the table level.

partitioning_storage_clause

Use the *partitioning_storage_clause* to specify storage characteristics for hash partitions and for range, hash, and list subpartitions.

Restrictions on *partitioning_storage_clause*

This clause is subject to the following restrictions:

- The TABLESPACE SET clause is valid only when creating a sharded table by specifying the SHARDED keyword of CREATE TABLE. Use this clause to specify the tablespace set in which table partition data is to be stored.
- The OVERFLOW clause is relevant only for index-organized partitioned tables and is valid only within the *individual_hash_partitions* clause. It is not valid for range or hash partitions or for subpartitions of any type.
- You cannot specify the *advanced_index_compression* clause of the *index_compression* clause.
- You can specify the *prefix_compression* clause of the *indexing_clause* only for partitions of index-organized tables and you can specify COMPRESS or NOCOMPRESS, but you cannot specify the prefix length with *integer*.

list_partitions

Use the *list_partitions* clause to partition the table on a list of literal values for each column in the *column* list. List partitioning is useful for controlling how individual rows map to specific partitions.

Restrictions on List Partitioning

List partitioning is subject to the restrictions listed in "Restrictions on Partitioning in General". The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
- You cannot specify more than one partitioning key column when partitioning an index-organized table.
- The partitioning key columns must be of type `CHAR`, `NCHAR`, `VARCHAR2`, `NVARCHAR2`, `VARCHAR`, `NUMBER`, `FLOAT`, `DATE`, `TIMESTAMP`, `TIMESTAMP WITH LOCAL TIMEZONE`, or `RAW`.
- Each list partitioning key column with a character data type that belongs to an `XMLType` table or a table with an `XMLType` column, or that is used as a sharding key column must have one of the `BINARY` following declared collations: `BINARY` , `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS` . For all these collations, partitions are matched using the collation BINARY.

AUTOMATIC

Specify `AUTOMATIC` to create an automatic list-partitioned table. This type of table enables the database to create additional partitions on demand.

When you create an automatic list-partitioned table, you specify partitions and partitioning key values just as you would when creating a regular list-partitioned table. However, you do not specify a `DEFAULT` partition. As data is loaded into the table, the database automatically creates a new partition when the loaded partitioning key values do not correspond to any of the existing partitions. If list partitioning is defined with a single partitioning key value, then the database creates a new partition for each new partitioning key value. If list partitioning is defined with multiple partitioning key columns, then the database creates a new partition for each new and unique set of partitioning key values. For each automatically created partition, the database generates a name of the form `SYS_Pn`. The database guarantees that automatically generated partition names are unique and do not violate namespace rules.

You can specify the `AUTOMATIC` keyword for list-partitioned tables, and list-range, list-list, list-hash, and list-interval composite-partitioned tables. For composite-partitioned tables, each automatically created list partition will have one subpartition, unless a subpartition template is defined for the table.

If a local partitioned index is defined on an automatic list-partitioned table, then local index partitions will be created when the corresponding table partitions are created.

Restrictions on Automatic List Partitioning

Automatic list partitioning is subject to the restrictions listed in "Restrictions on List Partitioning". The following additional restrictions apply:

- An automatic list-partitioned table must have at least one partition when created. Because new partitions are automatically created for new, and unknown, partitioning key values, an automatic list-partitioned table cannot have a `DEFAULT` partition.
- Automatic list partitioning is not supported for index-organized tables or external tables.
- Automatic list partitioning is not supported for tables containing varray columns.
- You cannot create a local domain index on an automatic list-partitioned table. You can create a global domain index on an automatic list-partitioned table.
- An automatic list-partitioned table cannot be a child table or a parent table for reference partitioning.
- Automatic list partitioning is not supported at the subpartition level.

STORE IN

The optional `STORE IN` clause lets you specify one or more tablespaces into which the database will store data for the automatically created list partitions.

> **Note:**
>
> You can change an automatic list-partitioned table to a regular list-partitioned table, and vice versa. You can also change the tablespaces into which the database will store data for automatically created list partitions. See the clause *alter_automatic_partitioning* of `ALTER TABLE` for more information.

list_values_clause

The *list_values_clause* of each partition must have at least one value. If the table is partitioned on one key column, then use the upper branch of the *list_values* syntax to specify a list of values for that column. In this case, no value, including NULL, can appear in more than one partition. If the table is partitioned on multiple key columns, then use the lower branch of the *list_values* syntax to specify a list of value lists. Each value list is enclosed in parentheses and represents a list of values for the key columns. In this case, individual key column values can appear in more than one partition; however, no complete value list can appear in more than one partition. List partitions are not ordered.

If you specify the literal `NULL` for a partition value in the `VALUES` clause, then to access data in that partition in subsequent queries, you must use an `IS NULL` condition in the `WHERE` clause, rather than a comparison condition.

The `DEFAULT` keyword creates a partition into which the database will insert any row that does not map to another partition. Therefore, you can specify `DEFAULT` for only one partition, and you cannot specify any other values for that partition. Further, the default partition must be the last partition you define. The use of `DEFAULT` is similar to the use of `MAXVALUE` for range partitions.

The string comprising the list of values for each partition can be up to 4K bytes. The total number of values for all partitions cannot exceed 64K-1.

The partitioning key column for a list partition can be an extended data type column, which has a maximum size of 32767 bytes. In this case, the list of values that you want to specify for a partition may exceed the 4K byte limit. You can work around this limitation by using one of the following methods:

- Use the `DEFAULT` partition for values that exceed the 4K byte limit.
- Use a hash function, such as `STANDARD_HASH`, in the partition key column to create unique identifiers of lengths less than 4K bytes. See STANDARD_HASH for more information.

Restriction on the *list_values_clause*

You cannot specify a `DEFAULT` partition for an automatic list-partitioned table.

> **See Also:**
>
> "Extended Data Types" for more information on extended data types

table_partition_description

The subclauses of the *table_partition_description* have the same behavior as described for range partitions in *table_partition_description*.

hash_partitions

Use the *hash_partitions* clause to specify that the table is to be partitioned using the hash method. Oracle Database assigns rows to partitions using a hash function on values found in columns designated as the partitioning key. You can specify individual hash partitions, or you can specify how many hash partitions the database should create.

Restrictions on Hash Partitioning

Hash partitioning is subject to the restrictions listed in "Restrictions on Partitioning in General". The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
- Partitioning key columns must be of type `CHAR`, `NCHAR`, `VARCHAR2`, `NVARCHAR2`, `VARCHAR`, `NUMBER`, `FLOAT`, `DATE`, `TIMESTAMP`, `TIMESTAMP WITH LOCAL TIMEZONE`, or `RAW`.
- Each hash partitioning key column with a character data type that belongs to an `XMLType` table or a table with an `XMLType` column, or that is used as a sharding key column must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

column

Specify an ordered list of columns used to determine into which partition a row belongs (the partitioning key).

individual_hash_partitions

Use this clause to specify individual partitions by name.

Use the *indexing_clause* to set the indexing property for a hash partition. Refer to the *indexing_clause* for more information.

Restriction on Specifying Individual Hash Partitions

The only clauses you can specify in the *partitioning_storage_clause* are the `TABLESPACE` clause and table compression.

> **Note:**
>
> If your enterprise has or will have databases using different character sets, then use caution when partitioning on character columns. The sort sequence of characters is not identical in all character sets. Refer to *Oracle Database Globalization Support Guide* for more information on character set support.

hash_partitions_by_quantity

An alternative to defining individual partitions is to specify the number of hash partitions. In this case, the database assigns partition names of the form `SYS_Pn`. The `STORE IN` clause lets you specify one or more tablespaces where the hash partition data is to be stored. The number of

tablespaces need not equal the number of partitions. If the number of partitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

For both methods of hash partitioning, for optimal load balancing you should specify a number of partitions that is a power of 2. When you specify individual hash partitions, you can specify both `TABLESPACE` and table compression in the *partitioning_storage_clause*. When you specify hash partitions by quantity, you can specify only `TABLESPACE`. Hash partitions inherit all other attributes from table-level defaults.

The *table_compression* clause has the same function as described for the *table_properties* of the table as a whole.

The *prefix_compression* clause and the `OVERFLOW` clause have the same function as described for the *index_org_table_clause*.

Tablespace storage specified at the table level is overridden by tablespace storage specified at the partition level, which in turn is overridden by tablespace storage specified at the subpartition level.

In the *individual_hash_partitions* clause, the `TABLESPACE` clause of the *partitioning_storage_clause* determines tablespace storage only for the individual partition being created. In the *hash_partitions_by_quantity* clause, the `STORE IN` clause determines placement of partitions as the table is being created and the default storage location for subsequently added partitions.

Restriction on Specifying Hash Partitions by Quantity

You cannot specify the *advanced_index_compression* clause of the *index_compression* clause.

> **See Also:**
>
> *Oracle Database VLDB and Partitioning Guide* for more information on hash partitioning

composite_range_partitions

Use the *composite_range_partitions* clause to first partition *table* by range, and then partition the partitions further into range, hash, or list subpartitions.

The `INTERVAL` clause has the same semantics for composite range partitioning that it has for range partitioning. Refer to "INTERVAL Clause" for more information.

Specify *subpartition_by_range*, *subpartition_by_hash* or *subpartition_by_list* to indicate the type of subpartitioning you want for each composite range partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement or subsequently created subpartitions.

After establishing the type of subpartitioning you want for the table, and optionally a subpartition template, you must define at least one range partition.

- You must specify the *range_values_clause* , which has the same requirements as for noncomposite range partitions.
- Use the *table_partition_description* to define the physical and storage characteristics of the each partition.

- In the *range_partition_desc*, use *range_subpartition_desc*, *list_subpartition_desc*, *individual_hash_subparts*, or *hash_subparts_by_quantity* to specify characteristics for the individual subpartitions of the partition. The values you specify in these clauses supersede for these subpartitions any values you have specified in the *subpartition_template*.
- The only characteristics you can specify for a hash or list subpartition or any LOB subpartition are TABLESPACE and *table_compression*.

Restrictions on Composite Range Partitioning

Regardless of the type of subpartitioning, composite range partitioning is subject to the following restrictions:

- The only physical attributes you can specify at the subpartition level are TABLESPACE and table compression.
- You cannot specify composite partitioning for an index-organized table. Therefore, the OVERFLOW clause of the *table_partition_description* is not valid for composite-partitioned tables.
- You cannot specify composite partitioning for tables containing XMLType columns.
- Each range, list, or hash subpartitioning key column with a character data type that belongs to an XMLType table or a table with an XMLType column must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

> **See Also:**
>
> "Composite-Partitioned Table Examples" for examples of composite range partitioning and *Oracle Database VLDB and Partitioning Guide* for examples of composite list partitioning

composite_list_partitions

Use the *composite_list_partitions* clause to first partition *table* by list, and then partition the partitions further into range, hash, or list subpartitions.

Specify *subpartition_by_range*, *subpartition_by_hash* or *subpartition_by_list* to indicate the type of subpartitioning you want for each composite list partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement and for subsequently created subpartitions.

After establishing the type of subpartitioning you want for each composite partition, and optionally defining a subpartition template, you must define at least one list partition.

- In the *list_partition_desc*, you must specify the *list_values_clause*, which has the same requirements as for noncomposite list partitions.
- Use the *table_partition_description* to define the physical and storage characteristics of the each partition.
- In the *list_partition_desc*, use *range_subpartition_desc*, *list_subpartition_desc*, *individual_hash_subparts*, or *hash_subparts_by_quantity* to specify characteristics for the individual subpartitions of the partition. The values you specify in these clauses supersede the for these subpartitions any values you have specified in the *subpartition_template*.

Specify AUTOMATIC to create an automatic list-range, list-list, list-hash, or list-interval composite-partitioned table. This type of table enables the database to create additional partitions on demand. The optional STORE IN clause lets you specify one or more tablespaces into which the database will store data for the automatically created partitions. The AUTOMATIC and STORE IN clauses have the same semantics here as they have for noncomposite list partitions. Refer to AUTOMATIC and STORE IN in the documentation on *list_partitions* for the full semantics of these clauses. Automatic composite-partitioned tables are subject to the restrictions listed in Restrictions on Composite List Partitioning and Restrictions on Automatic List Partitioning.

Restrictions on Composite List Partitioning

Composite list partitioning is subject to the same restrictions as described in "Restrictions on Composite Range Partitioning".

composite_hash_partitions

Use the *composite_hash_partitions* clause to first partition *table* using the hash method, and then partition the partitions further into range, hash, or list subpartitions.

Specify *subpartition_by_range*, *subpartition_by_hash* or *subpartition_by_list* to indicate the type of subpartitioning you want for each composite range partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement or subsequently created subpartitions.

After establishing the type of subpartitioning you want for the table, you must specify *individual_hash_partitions* or *hash_partitions_by_quantity*.

Restrictions on Composite Hash Partitioning

Composite hash partitioning is subject to the same restrictions as described in "Restrictions on Composite Range Partitioning".

subpartition_template

The *subpartition_template* is an optional element of range, list, and hash subpartitioning. The template lets you define default subpartitions for each table partition. Oracle Database will create these default subpartition characteristics in any partition for which you do not explicitly define subpartitions. This clause is useful for creating symmetric partitions. You can override this clause by explicitly defining subpartitions at the partition level, in the *range_subpartition_desc*, *list_subpartition_desc*, *individual_hash_subparts*, or *hash_subparts_by_quantity* clause.

When defining subpartitions with a template, you can explicitly define range, list, or hash subpartitions, or you can define a quantity of hash subpartitions.

- To explicitly define subpartitions, use *range_subpartition_desc*, *list_subpartition_desc*, or *individual_hash_subparts*. You must specify a name for each subpartition. If you specify the *LOB_partitioning_clause* of the *partitioning_storage_clause*, then you must specify *LOB_segname*.
- To define a quantity of hash subpartitions, specify a positive integer for *hash_subpartition_quantity*. The database creates that number of subpartitions in each partition and assigns subpartition names of the form SYS_SUBP*n*.

> **Note:**
>
> When you specify tablespace storage for the subpartition template, it does not override any tablespace storage you have specified explicitly for the partitions of *table*. To specify tablespace storage for subpartitions, do one of these things:
>
> - Omit tablespace storage at the partition level and specify tablespace storage in the subpartition template.
> - Define individual subpartitions with specific tablespace storage.

Restrictions on Subpartition Templates

Subpartition templates are subject to the following restrictions:

- If you specify TABLESPACE for one LOB subpartition, then you must specify TABLESPACE for all of the LOB subpartitions of that LOB column. You can specify the same tablespace for more than one LOB subpartition.
- If you specify separate LOB storage for list subpartitions using the *partitioning_storage_clause*, either in the *subpartition_template* or when defining individual subpartitions, then you must specify *LOB_segname* for both LOB and varray columns.

subpartition_by_range

Use the *subpartition_by_range* clause to indicate that the database should subpartition by range each partition in *table*. The subpartitioning column list is unrelated to the partitioning key but is subject to the same restrictions (see column).

You can use the *subpartition_template* to specify default subpartition characteristic values. See *subpartition_template*. The database uses these values for any subpartition in this partition for which you do not explicitly specify the characteristic.

You can also define range subpartitions individually for each partition using the *range_subpartition_desc* of *range_partition_desc* or *list_partition_desc*. If you omit both *subpartition_template* and the *range_subpartition_desc*, then the database creates a single MAXVALUE subpartition.

subpartition_by_list

Use the *subpartition_by_list* clause to indicate that the database should subpartition each partition in the table on lists of literal values from the *column* list. You can specify a maximum of 16 list subpartitioning key columns.

You can use the *subpartition_template* to specify default subpartition characteristic values. See *subpartition_template*. The database uses these values for any subpartition in this partition for which you do not explicitly specify the characteristic.

You can also define list subpartitions individually for each partition using the *list_subpartition_desc* of *range_partition_desc* or *list_partition_desc*. If you omit both *subpartition_template* and the *list_subpartition_desc*, then the database creates a single DEFAULT subpartition.

Restrictions on List Subpartitioning

List subpartitioning is subject to the same restrictions as described in Restrictions on Composite Range Partitioning.

subpartition_by_hash

Use the *subpartition_by_hash* clause to indicate that the database should subpartition by hash each partition in *table*. The subpartitioning column list is unrelated to the partitioning key but is subject to the same restrictions (see column).

You can define the subpartitions using the *subpartition_template* or the SUBPARTITIONS *integer* clause. See *subpartition_template*. In either case, for optimal load balancing you should specify a number of partitions that is a power of 2.

If you specify SUBPARTITIONS *integer*, then you determine the default number of subpartitions in each partition of *table*, and optionally one or more tablespaces in which they are to be stored. The default value is 1. If you omit both this clause and *subpartition_template*, then the database will create each partition with one hash subpartition.

Notes on Composite Partitions

The following notes apply to composite partitions:

- For all subpartitions, you can use the *range_subpartition_desc*, *list_subpartition_desc*, *individual_hash_subparts*, or *hash_subparts_by_quantity* to specify individual subpartitions by name, and optionally some other characteristics.
- Alternatively, for hash and list subpartitions:
  - You can specify the number of subpartitions and optionally one or more tablespaces where they are to be stored. In this case, Oracle Database assigns subpartition names of the form SYS_SUBPn.
  - If you omit the subpartition description and if you have created a subpartition template, then the database uses the template to create subpartitions. If you have not created a subpartition template, then the database creates one hash subpartition or one DEFAULT list subpartition.
- For all types of subpartitions, if you omit the subpartitions description entirely, then the database assigns subpartition names as follows:
  - If you have specified a subpartition template *and* you have specified partition names, then the database generates subpartition names of the form *partition_name* underscore (_) *subpartition_name* (for example, P1_SUB1).
  - If you have not specified a subpartition template *or* if you have specified a subpartition template but did not specify partition names, then the database generates subpartition names of the form SYS_SUBP*n*.

reference_partitioning

Use this clause to partition the table by reference. Partitioning by reference is a method of equipartitioning the table being created (the **child table**) by a referential constraint to an existing partitioned table (the **parent table**). When you partition a table by reference, partition maintenance operations subsequently performed on the parent table automatically cascade to the child table. Therefore, you cannot perform partition maintenance operations on a reference-partitioned table directly.

If the parent table is an interval-partitioned table, then partitions in the reference-partitioned child table that correspond to interval partitions in the parent table will be created during inserts into the child table. When an interval partition in a child table is created, the partition name is inherited from the associated parent table partition. If the child table has a table-level default

tablespace, then it will be used as the tablespace for the new interval partition. Otherwise, the tablespace will be inherited from the parent table partition. Refer to *Oracle Database VLDB and Partitioning Guide* for more information on referencing an interval-partitioned table.

constraint

The partitioning referential constraint must meet the following conditions:

- You must specify a referential integrity constraint defined on the table being created, which must refer to a primary key or unique constraint on the parent table. The constraint must be in `ENABLE VALIDATE NOT DEFERRABLE` state, which is the default when you specify a referential integrity constraint during table creation.
- All foreign key columns referenced in the constraint must be `NOT NULL`.
- When you specify the constraint, you cannot specify the `ON DELETE SET NULL` clause of the *`references_clause`*.
- The parent table referenced in the constraint must be an existing partitioned table. It can be partitioned by any method.
- The foreign and parent keys cannot contain any virtual (expression) columns that reference PL/SQL functions or LOB columns.

reference_partition_desc

Use this optional clause to specify partition names and to define the physical and storage characteristics of the partition. The subclauses of the *`table_partition_description`* have the same behavior as described for range partitions in *table_partition_description*.

If you specify this clause when creating a reference-partitioned child table whose parent is an interval-partitioned table, then the partition descriptors are used for the child table's non-interval partitions. Partition descriptors cannot be specified for interval partitions.

Restrictions on Reference Partitioning

Reference partitioning is subject to the restrictions listed in Restrictions on Partitioning in General. The following additional restrictions apply:

- Restrictions for reference partitioning are derived from the partitioning strategy of the parent table.
- Neither the parent table nor the child table can be an automatic list-partitioned table.
- You cannot specify this clause for an index-organized table, an external table, or a domain index storage table.
- The parent table can be partitioned by reference, but *`constraint`* cannot be self-referential. The table being created cannot be partitioned based on a reference to itself.
- If `ROW MOVEMENT` is enabled for the parent table, it must also be enabled for the child table.

> **See Also:**
>
> *Oracle Database VLDB and Partitioning Guide* for more information on partitioning by reference and "Reference Partitioning Example"

system_partitioning

Use this clause to create system partitions. System partitioning does not entail any partitioning key columns, nor do system partitions have any range or list bounds or hash algorithms. Rather, they provide a way to equipartition dependent tables such as nested table or domain index storage tables with partitioned base tables.

- If you specify only `PARTITION BY SYSTEM`, then the database creates one partition with a system-generated name of the form `SYS_Pn`.
- If you specify `PARTITION BY SYSTEM PARTITIONS` *`integer`*, then the database creates as many partitions as you specify in *`integer`*, which can range from 1 to 1024K-1.
- The description of the partition takes the same syntax as reference partitions, so they share the *`reference_partition_desc`*. You can specify additional partition attributes with the *`reference_partition_desc`* syntax. However, within the *`table_partition_description`*, you cannot specify the `OVERFLOW` clause.

Restrictions on System Partitioning

System partitioning is subject to the following restrictions:

- You cannot system partition an index-organized table or a table that is part of a cluster.
- Composite partitioning is not supported with system partitioning.
- You cannot split a system partition.
- You cannot specify system partitioning in a `CREATE TABLE ... AS SELECT` statement.
- To insert data into a system-partitioned table using an `INSERT INTO ... AS` *`subquery`* statement, you must use partition-extended syntax to specify the partition into which the values returned by the subquery will be inserted.

> **See Also:**
>
> Refer to *Oracle Database Data Cartridge Developer's Guide* for information on the uses for system partitioning and "References to Partitioned Tables and Indexes "

consistent_hash_partitions

This clause is valid only for sharded tables. Use this clause to create consistent hash partitions.

Each sharding key column with a character data type must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

directory_based_partitions

Use this clause to create a sharded table with directory-based sharding.

The restrictions that apply to sharded tables apply to tables sharded by directory.

Example: Create Sharded Table and Partition by Directory

```
CREATE SHARDED TABLE departments
  ( department_id  NUMBER(6)
  , department_name VARCHAR2(30) CONSTRAINT dept_name_nn NOT NULL
```

```
, manager_id    NUMBER(6)
, location_id   NUMBER(4)
, CONSTRAINT dept_id_pk PRIMARY KEY(department_id)
)
PARTITION BY DIRECTORY (department_id)
(
  PARTITION p_1 TABLESPACE tbs1,
  PARTITION p_2 TABLESPACE tbs2
);
```

In the example above, when you partition by directory the partition names `p_1` and `p_2` do not a have value list after them. This is different from partition by list.

consistent_hash_with_subpartitions

This clause is valid only for sharded tables. Use this clause to create consistent hash with subpartitions.

Each sharding key column with a character data type must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

range_partitionset_clause

Use this clause to create a range partition set.

In the `SUBPARTITION BY` clause, within the *`subpartition_template`* clause, you cannot specify a tablespace for a subpartition. That is, for range, list, and individual hash subpartitions, you cannot specify the `TABLESPACE` clause of the *`partitioning_storage_clause`*, and in the *`hash_subpartitions_by_quantity`* clause, you cannot specify the `STORE IN (`*`tablespace`*`)` clause.

In the `PARTITIONS AUTO` clause, within the *`subpartition_template`* clause of the *`range_partitionset_desc`* clause, you *can* specify a tablespace for a subpartition.

Each super sharding or sharding key column with a character data type must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

list_partitionset_clause

Use this clause to create a list partition set.

In the `SUBPARTITION BY` clause, within the *`subpartition_template`* clause, you cannot specify a tablespace for a subpartition. That is, for range, list, and individual hash subpartitions, you cannot specify the `TABLESPACE` clause of the *`partitioning_storage_clause`*, and in the *`hash_subpartitions_by_quantity`* clause, you cannot specify the `STORE IN (`*`tablespace`*`)` clause.

In the `PARTITIONS AUTO` clause, within the *`subpartition_template`* clause of the *`list_partitionset_desc`* clause, you *can* specify a tablespace for a subpartition.

Each super sharding or sharding key column with a character data type must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

attribute_clustering_clause

Use this clause to enable the table for attribute clustering. Attribute clustering lets you cluster data in close physical proximity based on the content of specified columns.

Attribute clustering can be based only on columns in *table* or on joined values from other tables. The latter is called join attribute clustering.

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for more information on attribute clustering

clustering_join

Use this clause to specify join attribute clustering. Use the `JOIN` clause to specify the joined values from other tables on which to base the attribute clustering. You can specify a maximum of four `JOIN` clauses.

cluster_clause

Use this clause to specify the type of ordering to use for the table: linear ordering or interleaved ordering. If you do not specify the `LINEAR` or `INTERLEAVED` keyword, then the default is `LINEAR`.

BY LINEAR ORDER

Use this clause to specify linear ordering. This type of ordering stores data according to the order of the specified columns. If you specify this clause, then you can specify only one clustering column group, which can contain at most 10 columns.

BY INTERLEAVED ORDER

Use this clause to specify interleaved ordering. This type of ordering uses a special multidimensional clustering technique, similar to z-ordering, that permits multicolumn clustering. If you specify this clause, then you can specify at most four clustering column groups, with a maximum of 40 columns across all groups.

clustering_columns

Use this clause to specify one or more clustering column groups.

clustering_column_group

Use this clause to specify one or more columns to be included in the clustering column group.

Restriction on Attribute Clustering Columns

Each character column in the clustering column group must have one of the following declared collations: `BINARY` or `USING_NLS_COMP`.

clustering_when

Use these clauses to allow or disallow attribute clustering during direct-path insert operations and data movement operations.

ON LOAD

Specify `YES ON LOAD` to allow, or `NO ON LOAD` to disallow, attribute clustering during direct-path inserts (serial or parallel) resulting either from an `INSERT` or a `MERGE` operation.

The default is `YES ON LOAD`.

ON DATA MOVEMENT

Specify YES ON DATA MOVEMENT to allow, or NO ON DATA MOVEMENT to disallow, attribute clustering for data movement that occurs during the following operations:

- Data redefinition using the DBMS_REDEFINITION package
- Table partition maintenance operations that are specified by the following clauses of ALTER TABLE: *coalesce_table*, *merge_table_partitions*, *move_table_partition*, and *split_table_partition*

The default is YES ON DATA MOVEMENT.

zonemap_clause

Use this clause to create a zone map on the table. The zone map tracks the columns specified in the *clustering_columns* clause.

- Specify WITH MATERIALIZED ZONEMAP to create a zone map. For *zonemap_name*, specify the name of the zone map to be created. If you omit *zonemap_name*, then the name of the zone map is ZMAP$_*table*.
- Specify WITHOUT MATERIALIZED ZONEMAP to not create a zone map. This is the default.

If you subsequently drop the table or use the ALTER TABLE statement to DROP CLUSTERING or MODIFY CLUSTERING ... WITHOUT MATERIALIZED ZONEMAP, then the zone map will be dropped.

> **See Also:**
>
> CREATE MATERIALIZED ZONEMAP for more information on zone maps

Restrictions on Attribute Clustering

The following restrictions apply to attribute clustering:

- Attribute clustering is not supported for temporary tables or external tables.
- The table being created must be a heap-organized table. However, tables specified in the *clustering_join* clause can be heap-organized or index-organized tables.
- Clustering columns must be of a scalar data type and cannot be encrypted.
- If you specify BY LINEAR ORDER, then you can specify only one clustering column group, which can contain at most 10 columns.
- If you specify BY INTERLEAVED ORDER, then you can specify at most four clustering column groups, with a maximum of 40 columns across all groups.
- For join attribute clustering:
  - The number of dimension tables cannot exceed four.
  - The join to the table or tables providing the attribute clustering columns must be on a unique key or primary key column to avoid row duplication.
- Attribute clustering will not order rows that are inserted using MERGE statements or multitable insert operations.

CACHE | NOCACHE | CACHE READS

Use these clauses to indicate how Oracle Database should store blocks in the buffer cache. For LOB storage, you can specify CACHE, NOCACHE, or CACHE READS. For other types of storage, you can specify only CACHE or NOCACHE.

If you omit these clauses, then:

- In a `CREATE TABLE` statement, `NOCACHE` is the default.
- In an `ALTER TABLE` statement, the existing value is not changed.

The behavior of `CACHE` and `NOCACHE` described in this section does not apply when Oracle Database chooses to use direct reads or to perform table scans using parallel query.

CACHE

For data that is accessed frequently, this clause indicates that the blocks retrieved for this table are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables.

> **See Also:**
>
> *Oracle Database Concepts* for more information on how the database maintains the least recently used (LRU) list

As a parameter in the *`LOB_storage_clause`*, `CACHE` specifies that the database places LOB data values in the buffer cache for faster access. The database evaluates this parameter in conjunction with the *`logging_clause`*. If you omit this clause, then the default value for both BasicFiles and SecureFiles LOBs is `NOCACHE LOGGING`.

Restriction on CACHE

You cannot specify `CACHE` for an index-organized table. However, index-organized tables implicitly provide `CACHE` behavior.

NOCACHE

For data that is not accessed frequently, this clause indicates that the blocks retrieved for this table are placed at the least recently used end of the LRU list in the buffer cache when a full table scan is performed. `NOCACHE` is the default for LOB storage.

As a parameter in the *`LOB_storage_clause`*, `NOCACHE` specifies that the LOB values are not brought into the buffer cache. `NOCACHE` is the default for LOB storage.

Restriction on NOCACHE

You cannot specify `NOCACHE` for an index-organized table.

CACHE READS

`CACHE READS` applies only to LOB storage. It specifies that LOB values are brought into the buffer cache only during read operations but not during write operations.

logging_clause

Use this clause to indicate whether the storage of data blocks should be logged or not.

> **See Also:**
>
> *logging_clause* for a description of the *`logging_clause`* when specified as part of *`LOB_parameters`*

result_cache_clause

Use this clause to determine whether the results of statements or query blocks that name this table are considered for storage in the result cache.

You can use mode `DEFAULT` or mode `FORCE` for result caching, with `STANDBY` enabled or disabled.

- `DEFAULT`: Result caching is not determined at the table level. The query is considered for result caching if the `RESULT_CACHE_MODE` initialization parameter is set to `FORCE`, or if that parameter is set to `MANUAL` and the `RESULT_CACHE` hint is specified in the query. This is the default if you omit this clause.
